If the child's face begins to flush and show signs of the physiological effects of the drug, the dose can be reduced in frequency. Do not forget in these cases to give an emetic if there is anything in the stomach which may be causing the spasm, or a cathartic, if there be reason to suspect intestinal disturbance as the cause.

In nervous disturbances and undefinable and transitory disorders of children, the *bromides*, in doses of one or two grains every ten or fifteen minutes, will often prove of great benefit.

You will often meet with children of a nervous, excitable frame of mind, who are, perhaps, naturally of a sensitive, nervous temperament, who are disturbed by the slightest noise, and are unable to go to sleep before ten or eleven o'clock at night. In such cases you will find it necessary to give a nervous sedative. An excellent effect will be produced by *chamomilla* in some one of its forms, as the tincture, administered in minim doses, every fifteen or twenty minutes. Put a teaspoonful in half a tumbler of water, and let the child drink it freely.

A single drop of the *wine of ipecac*, repeated every fifteen or twenty minutes, will often produce the most marked relief, both from vomiting and diarrhoea. Administered in this manner, the drug is not nauseous, and is easily taken.

I now make a statement, upon the authority of Trousseau and his enthusiastic successor, which may appear to you, as it once did to me, incredible—viz., that *one-sixtieth of a grain of calomel*, taken every hour for ten or twelve hours, will relieve the headache of syphilis occurring at night.

I have administered it in one-fortieth-grain doses in this manner, and have obtained the results which they claimed for it, but I have not yet tried it in sixtieth-grain doses. The relief was very marked by the second or third night. It is not intended to take the place of iodides which are given in such cases.

Nursing children often vomit or regurgitate their food; teaspoonful doses, every ten or fifteen minutes, of a solution of one grain of *calomel* to a pint of water, will often relieve this. One *twenty-fourth of a grain of mercury* with chalk, every fifteen or twenty minutes, is of great benefit in the vomiting and non-inflammatory diarrhoea of children.

Where the diarrhoea is accompanied by *mucous passages*, indicative of a certain degree of inflammatory action, or enteritis, benefit will be derived from the administration of one teaspoonful of a solution of *bichloride of mercury* (corrosive sublimate), one grain to the quart, every hour.

Another extraordinary statement, which at first seemed to me to be fabulous, and may seem so to you, but which, nevertheless, you will find to be based upon clinical facts: Put a grain of *tartar emetic* into one quart of water; teaspoonful doses of this solution every half hour will prove effectual for the relief of the *wheezing* and *cough* accompanying a slight *bronchitis* in children.

A single drop of the *tincture of nux vomica* given every ten minutes will often produce most marked relief in *sick headache* not of a neurotic origin. It should be given immediately after or soon after meals.

It is well known that *cantharides*, when given in large doses, is liable to cause inflammation of the urinary tract; but it has been found that a *single drop of the tincture* every hour will in many cases relieve *vesical catarrh*.

A *single drop of the tincture of digitalis*, given to a patient suffering from symptoms due to *organic heart disease* when digitalis is indicated, administered at intervals of an hour or half hour, according to the severity of the symptoms, will often give greater relief than larger doses, and without liability to ill effects.

For the *diarrhoea of children*, accompanied with slight *inflammation*, straining, and the passage of *jelly-looking matter*, but not true dysentery, *five drops of castor-oil*, given every hour in water with sugar and gum, is an excellent remedy.

In *orchitis* and *epididymitis* and *dysmennorrhoea* not of a membranous, obstructive, or neuralgic character, two-minim doses of *tincture of pulsatilla* every hour will afford greater relief than any

other mode of treatment. For *flatulence, fluttering and palpitation* at the menopause, *one-fiftieth grain doses* of the *extract of Calabar bean* every half hour for six or eight doses, and similarly repeated after stopping it for three hours, will prove an effectual remedy. In *amenorrhœa* not due to anæmia, minim doses of the *fluid extract of ergot* every half hour for five or six hours, the day before and again on the day on which it should occur, will be beneficial. There are many cases of *febrile movement, with dry, hot skin*, a full, bounding pulse, the mucous membrane of the throat and nose probably dry—cases in which the febrile movement is not the commencement of one of the continued fevers; the *tincture of aconite*, one-third to one-half a minim given every fifteen minutes, will be found of decided benefit. Visiting the patient shortly after the commencement of this treatment, you will often find him in a little perspiration; the medicine may then be administered at longer intervals, every half-hour or longer, according to the indications. The *tincture of aconite*, administered in a similar manner, is also useful in cases of commencing so-called cold in the head. It is likewise useful in cardiac hypertrophy with palpitation, severe headache, and disturbances of the nervous system due to increased force of the heart-beat.

Two minims of the *tincture of hamamelis* every half-hour will often control hæmorrhages.

The *tincture of belladonna* in minim doses, given every half-hour, is a good remedy in cases of *nasal catarrh*, and bronchitis accompanied by free secretion. You should cease to give the drug for a while after eight or ten doses have been administered, as it is less quickly eliminated from the system than the other medicines of which we have already spoken. In cases of *pulmonary ædema* with failure of heart power, *belladonna* thus administered is of benefit in retarding the exudation of serum, and in overcoming the failure of heart power.

Two grains of the *chloride of ammonium*, combined with ten or fifteen minims of the *tincture of cubebs*, given every half-hour, oftentimes controls acute pharyngitis and superficial inflammations of the other tissues about the throat. For *inflammation of the throat* dependent upon a *gouty diathesis*, add to this mixture ten minims of the *ammoniated tincture of guaiac*, and administer every hour.

In the headache of *migraine*, one grain of the *citrate of caffeine* given every half-hour will often produce most marked relief.

In *neuralgias* about the face or head, three-minim doses of the *tincture of gelsemium* every half-hour will often act almost miraculously, and leave no ill effects.

For certain kinds of *headaches* (especially those which are periodical and not of malarial origin), fifteen-minim doses of fluid extract of *guarana* given every fifteen minutes will very frequently relieve. If it does not relieve in four doses, increase the dose to thirty minims.

CORRESPONDENCE.

A Peculiar Type of Fever.

EDS. MED. AND SURG. REPORTER:—

Under the above title, Dr. J. M. Pinkston, in a recent issue of your journal (March 3) relates the history of an epidemic of fever which he is pleased to call a peculiar type, though the peculiarity appears to consist in the fact that the patients recovered in thirty-six to seventy-two hours; we will however return to this point later.

The article concludes thus—"As to diagnosis, I should like to have the opinion of older members of the profession." While I cannot lay claim to the latter distinction, I still feel that the former field is open to me.

For our purpose, it is perhaps better to place the epidemic fever of Dr. Pinkston, and the disease which I hope to show that it is, side by side.

"Peculiar Fever."

Prodromes.—Identical.

Invasion.—The fever is usually ushered in with a chill, followed by headache, nausea, vomiting; in some cases cold feet and hands, tenderness and continuance of pain, in most cases, over region of stomach, and almost invariably tenderness at a point midway between the hips, but no iliac tenderness.

Tongue.—Identical.

Bowels and Stomach.—Generally typhantic; stomach almost invariably so.

The bowels are usually constipated.

Fever.—

"I should have stated that the fever in the commencement is high in children, sometimes attended with convulsions."

"The symptoms in the commencement, in some cases, indicate violent congestion of the stomach and bowels, and, as indicated by breathing, congestion of lungs, but there are no physical signs thereof."

"Some cases also have slight sore throat, enlargement of the tonsils, and a little irritation of bronchial tubes, and consequently a little cough."

(Reference to the article will show that a plan of treatment has been used that, in this city at least, is a well-recognized one for typhoid fever; so that we may say)

Treatment.—Identical.

Diet and Hygiene.—Identical.

"If improperly treated, or if not treated at all, and in some cases in spite of treatment, it will last from ten to six weeks."

Typhoid Fever.

(Mild and abortive form.)

Prodromes.—Identical.

Invasion.—Fever usually ushered in with a chill or chilly sensations, headache, nausea, loss of appetite, etc. Complaints of soreness, pain, etc., as much in stomach and at the "midway point" as anywhere else.

Tongue.—Identical.

Bowels and Stomach.—The same, almost always.

Diarrhœa is often wanting. (J. M. DaCosta.)

Fever.—

Temperature evening of fourth day 104°. (Wunderlich.)

Other symptoms of grave disturbance of the nervous system show themselves in violent general convulsions. (Da Costa.)

Have not all of us seen typhoid fever so commence? Is this violent congestion of the stomach and bowels not an illustration of the poison being swallowed and acting directly upon the tissue with which it comes in contact? as milk contaminated by water containing fecal fermentations. (Prof. Stillé.)

Treatment.—Identical.

Diet and Hygiene.—Identical.

Is this not often the case with typhoid, which may terminate in sixteen days or less?

As above said, the doctor states that the patients recovered in from thirty-six to seventy-two hours. Are we to understand that a patient will be well, sick and well again in the above period? An analysis of the symptoms would lead one to suppose that the convalescence was rather tardy, once more resembling typhoid fever.

So on the whole I would be inclined to call the "peculiar type of fever," a typical example of the mild or abortive typhoid, such as Jürgensen describes (*Sammlung Klinischer Vorträge*, Nov. 1, 1873). It is the short duration, as Prof. DaCosta tells us, that is characteristic of abortive typhoid, and the changes are so marked and rapid that the defervescence is accomplished in a few days.

W. A. EDWARDS, M. D.

1210 Spruce St., Phila.

NEWS AND MISCELLANY.

Annual Commencement of the Woman's Medical College.

The annual commencement of the Woman's Medical College was held in Association Hall, March 15th. Thirty-five women received the degree of M. D. The Rev. Dr. Henry C. McCook opened the exercises with prayer, and then President T. Morris Perot presented the diplomas.

The address to the graduating class was delivered by Professor W. H. Parish. After reviewing the training the students had undergone, he said:

"Who has not been asked, Does not frequent contact with pain and suffering, disease and death, render one indifferent to the occurrence of such in others? Is not sympathy supplanted by stony stoicism? How great the error to suppose so! The experiences of a physician's life educates him to avoid the emotional, and to keep coolness and judgment in the ascendancy. His sympathies are none the less. Long years of professional work will but enlarge in you true, active sympathy. The physician's studies ennoble his humanity. The study of any manifestation of nature gives profit to the human mind.

"Away, then, with the fallacious reasoning that woman may with propriety devote her capabilities to the study of the lily or the rose, or of the spider or beetle, but cannot study man, the noblest work of God. The relations of the physician to the general public are becoming daily of a higher and more responsible character. I will briefly enumerate some of the matters in reference to which the public demand that the physician shall be well informed. Among such matters are, for instance, the successful operation of the National Board of Health, the establishment of State Boards of Health with properly-defined duties and powers, the prevention of epidemic diseases, the preservation of the purity of water courses, the prevention of the adulteration of food, the establishment of medical Boards for the inspection of schools and school houses, the location and inspection of hospitals and almshouses, the support of rightly-managed medical colleges by means of proper legislation; as, for instance, a more restricted and cautious conferring of college charters, and the greatly-needed revision of State anatomical acts."

Murder Will Out.

A female smuggler named Bronar met with a serious accident at Lyons on December 16, while in the exercise of her illegal calling. She had concealed several bladders full of alcohol under her petticoats in order to pass them through the *octroi* free of duty. Being arrested on suspicion of smuggling, she pierced the bladders with a pin, and the liquor ran out before she reached the police station. On arriving there, however, she incautiously attempted to dry her clothes before a red-hot stove. Being saturated with alcohol, they took fire. Madame Bronar received such injuries before the flames could be extinguished that her life was in danger.

The Moon and the Weather.

At the last meeting of the British Association, Sir W. Thompson delivered an address upon the tides. While explaining the theory of the moon's influence on the tides, he incidentally touched on the supposed influence of the moon's changes upon weather, and pointed out that the comparison of most careful and complete indications of the barometer, thermometer, and anemometer, and the times of the new and full moon and half moon, had failed to establish any relation whatever between them, and had proved, on the contrary, that if there was any dependence of the weather on the phases of the moon it was only to a degree imperceptible to ordinary observation.

Glass Coffins.

From *Lyon Med.*, February 11, we learn that in order to prevent the diffusion of the products of decomposition of human bodies in the air and water, Dr. A. Meyer proposes to substitute glass coffins for those made of wood. They will be opaque, very thick, and formed only of two parts, hermetically closed by a silicated mastic as indestructible as the glass itself. By suitable pressure, an anti putrescent gaseous atmosphere (carbonic acid, for example) may be introduced into the coffin, and preserve the corpse from putrefaction during an indefinite period of time. Dr. Meyer adds that these coffins can be readily supplied by the trade at prices which will more and more approximate to those paid for wooden coffins.

To Restore Faded Ink.

In order to restore faded ink, all that is necessary, according to the *Boston Journal of Chemistry*, is to moisten the paper with water, and brush over the writing with a solution of sulphide of ammonium. The ink will become black immediately, from the formation of the black sulphide of iron. Of course this means of restoration is not applicable with aniline inks.

Officers of the Cincinnati Obstetrical Society for 1883.

President.—Dr. J. Trush.

Vice-President.—C. O. Wright.

Recording Secretary.—Clara Ellsbury.

Corresponding Secretary.—J. G. Hyndman.

Treasurer.—Geo. E. Jones.

Personals.

—D. H. Macnaughton Jones, M. C. H., F. R. C. S. T., and Edin. Professor of Obstetrics and Gynecology in the Green's College, Cork, surgeon of several hospitals, but founder and especially interested in the Cork Ophthalmic and Aural Hospital, has been invited to London, a more extended field of usefulness. Dr. Jones is favorably known in this country by his valuable contributions to medical periodical literature, and by his published volumes.

Items.

—Dr. G. Hother recommends the use of hazeline in prolapsus ani.

—M. Dupré concludes that the liver is the chief source of urea formation.

The bicycle is getting to be a common mode of travel among physicians in England.

—It is reported that the British public spend annually \$5,000,000 for secret remedies.

—M. Desnos has found resorcin very effective in reducing the temperature of typhoid fever.

—M. Burcq ("*Comptes Rendus*") shows that copper has a powerful disinfectant and antiseptic action.

—The award of \$20,500 to the four surgeons summoned to attend President Garfield has been received by them.

—In Ontario, Canada, there is one doctor to every 1,125 inhabitants—so it appears from the last Medical Register.

—It is reported that certain foreign manufacturers of glycerin adulterate it with over twenty-five per cent. of glucose.

—Velpeau has reported four cases of laying open the internal carotid artery in operations for the removal of tonsils.

—A new hospital at Dayton, O., has recently been completed and opened. It cost \$75,000, and has a capacity of 200 beds.

—A Chair of Laryngology has been established in the Royal University of Rome, and Dr. Zaverthal has been appointed to fill it.

—Dupuytren first called attention, in 1828, to the frequency with which deformity of the chest is associated with enlarged tonsils.

—A Physical Aspect of Abscesses.—Professor in physics: "What is Boyle's law?" Student, with a carbuncle: "To break out in the most inconvenient place."

—Dr. Squire recommends a solution of bromic ether in water (1 to 200) for administration in whooping cough, as well as for angina pectoris and spasmodic pain.

—A case of polyorchism was observed in Bulgaria, on a farmer eighteen years of age. There were three testicles, two being on the right in the scrotum, one above the other.

—"Well, madam, how's your husband today?" "Doctor, he's no better." "Did you get the leeches?" "Yes, doctor, but he could only take three of them raw; I had to fry the rest."

—Dr. Albert G. Craig, Vevay, Indiana, suggests the substitution of linseed oil for olive oil in the composition of liniments. He has found it better, as well as much cheaper.

—U. S. Grant, when asked to sign the petition in favor of making all physicians equal before the law in the government service, said he would "*give homeopaths no encouragement directly or indirectly.*"

—The recent epidemic of diphtheria in Russia has been followed by a still more virulent outbreak of scarlatina, which a Russian newspaper describes as more devastating than the most sanguinary war.

—A new sanitary journal has just appeared at Naples under the editorship of Dr. Achille Spatuzzi. Its title is "*Il Propugnatore della Salute, Periodico d'Igiene Popolare*,"—the advocate of health, a periodical of popular hygiene.

OBITUARY NOTICES.

S. B. ROBBINS, M. D.

Dr. S. B. Robbins died at Shelbyville, Ind., February 22, 1883, after a lingering illness, at the age of 39. He was much respected, and enjoyed an extensive and successful practice until failing health compelled him to retire.

ALVILDA G. SMITH.

At Adamsburg, Snyder county, Pa., March 14, 1883, died Alvilda G., wife of Dr. A. M. Smith, aged 33 years.

A most gentle and estimable woman, much beloved by all who were fortunate enough to know her, has gone from us. May God comfort her husband and parents. F. P. D.

QUERIES AND REPLIES.

MESSRS. EDS: What is the best antidote for alcoholic poisoning, emetics excepted? What the best to dissipate the odor in the breath?

Oblige yours respectfully, I. H. C.

Ans.—You will find these topics fully discussed in Napheys' *Medical Therapeutics*, 7th ed., pp. 557-571, to which we would refer you.

Dr. P. S., of Va. We can readily publish any pamphlet which you wish to have issued. On receipt of MS. we will send you an estimate.

MARRIAGES.

ARMSTRONG—BLAIR.—On Wednesday, February 28, 1883, by the Rev. R. B. Foresman, Milton N. Armstrong, M. D., of Blairstown, N. J., and Lizzie H. Blair, of Johnsonburg, N. J.

OTT—FORD.—On Tuesday evening, February 27, 1883, by Rev. L. P. Hornberger, Dr. Lambert Ott, formerly of Independence, Missouri, and Ida L., youngest daughter of the late George Ford, of Philadelphia.

DEATHS.

FISHER.—At Cologne, Germany, on February 13, 1883, at six o'clock, a. m., of congestion of the lungs, Alexander Ming Fisher, M. D., in the 26th year of his age, son of the late Lieut. Edward M. Fisher, and grandson of the late Col. Alexander Ming.

MILLER.—On March 6, 1883, after a lingering illness, Mary Agnes, only daughter of Dr. A. M. Miller, of Bird-in-Hand, Pa., in the 22d year of her age.

LECTURE.

CLINICAL LECTURE ON THE DISEASES OF WOMEN.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND
SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS.

Infantile Leucorrhœa.

GENTLEMEN: The little girl, nine years old, whom I first bring before you, is suffering from a very profuse leucorrhœa, which, her mother informs me, she has been unable to cure by any of the remedies which she has employed, and which has now lasted for two months. I, of course, made a vaginal examination, and, on separating the labia, I found that the whole vulva was about the color of red flannel, and bathed with a copious leucorrhœal discharge. The meatus urinarius was also seen to be in the same condition, and urethritis has, no doubt, been set up by the spreading of the irritation. If it had been necessary, I could have introduced a small glass speculum into the vagina; but this was not required to make a diagnosis, as I saw exactly what was the matter without resorting to this.

Not infrequently mothers will bring their little girls to you in this condition, and they will sometimes be in a state of great agitation, because they are afraid the trouble has been the result of injury done the children. There is ordinarily no reason whatever to suspect anything of the kind, and you can at once quiet the anxious mother's mind. The affection is a perfectly simple one, and is perfectly curable also. What is it, then?

It is generally known as infantile leucorrhœa; but infantile vaginitis would be a better term for it.

Now as to its causes. One of the most frequent of these is neglect of hygienic precautions. There is generally no intentional neglect on the part of the mother or nurse; but, on account of the undeveloped condition of the part, an accumulation of hardened secretion sometimes collects in the same way as that which not infrequently gives rise to balanitis in the male child. Another common cause is the depreciated condition of the child's system, such as that due to *spanæmia*, in which all the mucous membranes are apt to become more or less affected. Thus, there is often gastric and intestinal, as well as nasal catarrh. A third cause that may be mentioned is reflex influence from the rectum. The cause of the irritation in the rectum is usually *ascarides*, and an afflux of blood to the part is caused by the itching and irritation.

In some instances, the *ascarides*, by getting into the vagina itself, are the direct cause of the trouble. The prognosis of this affection is, that it can be cured at once if it is properly treated.

In the treatment, the first thing to do is to see if there are any worms present, and if so (or there is any reason to suspect that such is the case), use an injection of warm salt water, as this form of *ascaris* (the *ascaris vermicularis*), as well as others, is unfavorably affected by salt. The next thing to do is to get the child's general system in the best condition possible by appropriate food, iron, vegetable tonics, and the hypophosphites. It is better to depend on nourishing diet, however, than on medicinal agents. If after the worms

have been gotten rid of the vaginal irritation and discharge should continue, or if no worms should be found to be present, local treatment will be required. The vagina should be thoroughly washed out by means of a syringe provided with a small nozzle, which ought to be well oiled before being introduced. In order that the canal may be perfectly cleansed, the child should be placed upon the back. In some cases the mere removal of the accumulated secretion, which is a constant source of irritation, is all that is necessary; but if the trouble has gone on for some time, this may not be sufficient. Something further is then needed, and one of the best applications to use is the old-fashioned black wash (calomel and lime-water) in the strength of one ounce to the pint of water. Before using this, (which should be done twice a day) an injection of simple warm water should be made. I have never yet seen a case of infantile leucorrhœa that could not be cured by such treatment as this; so that there is no necessity of resorting to astringents and nitrate of silver, which may perhaps do harm. If it is adopted here, I have no doubt that in less than two weeks this child will be entirely well.

But there is one mistake which is apt to be made by the physician in these cases, on account of which a much longer time may be required for a case than is at all necessary, and that is, the failure on his part to show the mother or nurse how to introduce the nozzle of the syringe properly. Mothers, unless they are especially instructed in regard to this point, never carry the nozzle more than an eighth of an inch up into the vagina, and as it is above this that the degenerating pus is found, there will be no improvement, simply because the injections fail to reach the real source of trouble. It is not enough even to show the mother how to use the syringe, but you should also watch her do it, and see that the upper part of the vagina is reached. In a child of this age, the rectal tube of a Davidson syringe should be employed.

Recurring Attacks of Pelvic Peritonitis in Connection with Ovaritis and Salpingitis.

Our next patient is Mrs. Mary H., a native of the United States, and 33 years of age, who has been married for ten years. She has had two children, and the youngest is now seven years old. She says she got quite well after the birth of her last child; but has been complaining for more than six years. She nursed the child for about seven months, when her menses came on, and since that time she has never been well.

This is not an uncommon history: the trouble not commencing at child-birth, but with the resumption of ovulation. Since she has stopped nursing the child, she says she has had constant pain in the lower part of the abdomen, and twice she has been very much bloated. The first time that this bloating occurred, she did not suffer much pain with it; but the second time it was accompanied with very severe pain, and she was confined to bed for a time. The second attack lasted for about two months. In regard to her menstrual periods, she says she does not have much more pain than usual at that time, but that she has considerable pain for three or four days before the flow, and that it is somewhat relieved by the latter. She sometimes has backache in addition to the constant abdominal pain, but is always able to attend to her household duties.

When a vaginal examination was made in this case, it was found that the uterus was in its normal position, and, on mapping it out, by means of conjoined manipulation, that there was more or less fixation of the organ. On either side of the uterus was discovered a mass which was tender under pressure, and which extended outwards. The fixation of the uterus indicates with certainty that the patient has had pelvic peritonitis; and there can be little doubt that the two attacks of which she has spoken were of this nature. The bloating which she mentioned, and which she thought was dropsy, was in all probability the tympanites which so frequently accompanies pelvic peritonitis.

What is the diagnosis here? All the gentlemen who have examined the case, agree with me in believing that both the fallopian tubes, as well as both the ovaries, are enlarged, since these parts can be mapped out with unusual ease in this instance. It is altogether probable, therefore, that after she ceased nursing her child, she became affected with chronic ovaritis and chronic salpingitis. Mr. Lawson Tait, the distinguished English surgeon, has recently pointed out the fact that repeated attacks of pelvic peritonitis occur as a result of this condition of the ovaries and tubes. Up to the time that Mr. Tait's paper appeared in the *British Medical Journal* last summer, I had never had my attention called to this point, and consequently my experience has not yet been very extensive in regard to it; but I have already seen enough to convince me that he is quite right in attributing these recurring attacks of pelvic peritonitis to the escape of irritating fluid from the inflamed tubes into the peritoneum. In the present instance, the first attack

of peritonitis was evidently very light; but the second one seems to have been considerably more severe. Although the tubal enlargements can apparently be made out with unusual clearness in this case, the diagnosis, you must understand, is not a positive one.

I have now operated in five cases where the same diagnosis was made, but they were all cases in which the patient's sufferings had become intolerable. The fifth operation was performed only four days ago. The patient was completely bed-ridden, and had become so addicted to the use of opium that she required no less than ten grains of sulphate of morphia by hypodermic injection each day. Sometimes she has taken as much as sixteen grains in the twenty-four hours. To-day, for the first time, her allowance of the drug has been diminished. Her ovaries and fallopian tubes, I may say in passing, were found to be in the typical condition described by Tait.

In the case now before you the ovaries and tubes are, no doubt, in very much the same state; and yet this is a case in which I certainly would not recommend the operation for their removal. The reason is, that this woman does not suffer to such an extent, in my opinion, as to justify a resort to so radical a procedure. I cannot impress upon you too strongly the fact that the dangers of this operation are very great; and the great fault that I have to find with Mr. Tait, is that he makes too light of them altogether. I cannot believe that the high standard of success which he has thus far maintained, will be kept up in the future. In the five cases which I have now operated upon myself, there is not one patient to whom death would not have been a welcome relief from her sufferings. A woman who is in such a deplorable condition as all these even before this operation, is worse than a leper, and everybody who has anything to do with her case soon gets sick of it. Such patients almost invariably become opium-eaters. The present case is fortunately not of this desperate character. The dividing line must be drawn between suitable and unsuitable cases for operation; and nothing would induce me to operate here, as long as she remains no worse than she is now. She does not suffer enough, and her life is by no means miserable enough, to render it proper to subject her to the dangers of such an operation. Saturday, however, I saw a case in which I would not hesitate an instant to operate, because the poor woman had had so many attacks of inflammation, and was so utterly wretched in every way.

Here, instead of an operation, I would recom-

mend such measures as the repeated painting of the roof of the vagina with compound tincture of iodine, the external application of blisters or tincture of iodine, and the continued use of galvanism and the hot-water douche.

Subinvolution and Antelexion in Connection with Laceration of the Cervix Uteri.

Our last patient to-day is Mrs. Mary P—, 24 years of age, and a native of the United States. She has had one child and three miscarriages, the last of which occurred one year ago. She says she has been complaining for the last three or four months, and has suffered from severe pain in the back and lower part of the abdomen. At her monthly periods, which last for a week, she flows very profusely. She also suffers a great deal of pain at the time of menstruation, and would go to bed if it were possible for her to do so. Between her periods she has a profuse leucorrhœa. All the miscarriages, it seems, have occurred since the birth of her living child, and in answer to closer questioning, she tells me that the menorrhagia has really continued ever since her baby was born, but has increased of late. The pains also she has had for a long time, but it is only within the last three or four months that they have become so severe. Finally, she says that there has been no change in her condition of life which would account for the aggravation of symptoms of which she has spoken.

When I made a physical examination in this case, the moment the finger was passed up into the vagina, it was found that the uterus was tilted forward to a marked extent, and that the cervix was badly lacerated on both sides. The uterus was then found to be not simply anteverted, but in a state of antelexion, and was also both large and tender. The ovaries were, apparently, altogether normal. Such a condition having been found, the most of the patient's symptoms are already accounted for. When the child was born the cervix uteri was lacerated, and, no doubt in consequence of this, involution was interfered with. The menorrhagia depends on the abnormal condition of the lining mucous membrane of the uterus, which was in all probability affected by subinvolution. The diagnosis of the case is, therefore, *first*, laceration of the cervix; *second*, subinvolution of the uterus; *third*, antelexion of the uterus, in consequence of the subinvolution; and, *fourth*, fungoid degeneration of the endometrium. Some European writers call this latter condition *endo metritis polyposa*, but the name is not a correct one.

In order to be properly treated, this patient

should be admitted to the Woman's Hospital. She should be kept quiet for a week, have her bowels regulated, and be treated with hot vaginal injections. A Sims' speculum should then be introduced, and by means of a copper wire curette, such as I now show you, the whole endometrium should be scraped, in order to remove all the little polypoid excrescences with which it is covered. After that she should remain in bed for three or four days, the hot vaginal injections being kept up in the meanwhile, and then an operation for the repair of the lacerated cervix should be performed. The sutures could be removed in about ten days, and the next thing would be to restore the uterus to its proper position, in which it would probably remain without the use of a pessary. The patient could then be discharged, and I believe that she would soon be entirely well.

You observe that the woman is very pale and weak from loss of blood; but as long as this condition of menorrhagia continues, it is adding fuel to the flames to give her iron or quinia. Iron, I have found, is the very worst thing that you can give such a patient, and this is a point which I trust you will not lose sight of. As to the leucorrhœa, that will no doubt disappear as soon as her system, freed from the constant drain from which it now suffers, has regained its normal strength and tone.

COMMUNICATIONS.

UTERINE DYSKINESIA.

BY JOHN AULDE, M. D.,
Of Philadelphia.

Uterine dyskinesia is described by Dr. Grailly Hewitt as "a symptom and effect of uterine disease so common and so important that it deserves to be considered separately and distinctly," and is used by him to denote "impairment of the power of locomotion." (Reynolds' System of Med., vol. v., page 700.) That it is a common symptom will be admitted by every professional man in general practice, and that it is an important one, the numerous failures of the multitudinous remedies recommended for uterine troubles must be recorded as indisputable proofs. The mere treatment of the "effect" of disease, without a knowledge of the cause, and an attempt to remove the obstacle to the normal performance of the functions of the organs and tissues involved in the pathological processes, would indeed be superficial and short-sighted; again, any remedies which may be adopted with a view to simply

palliate a "symptom" of disease, so long as the *vis medicatrix nature* is unable to overcome the obstruction to natural operations, will yield the practitioner but little comfort or satisfaction in the art of healing, while the ultimate failure of his methods will undoubtedly cause him to long for the time when medicine, like chemistry, philosophy, etc., shall occupy its proper position in the circle of the sciences. That it does not occupy this position to-day, the unsettled condition of the minds of professional men, together with the various changes which have been suggested and adopted during a century of progress, are the evidences conclusive that the confines of that field have not yet been reached, where medicine can claim to occupy the position of an exact science.

These remarks, though apparently somewhat of a digression from the subject for consideration, are not prompted by any feelings of dissatisfaction with the results attained by a long list of most noble and honored workers; nor is it the intention to offer any suggestions with the object of introducing changes or modifications, but in the hope that these preliminary observations may be considered a sufficient reason for the presentation of a most simple remedy, or method of treatment, for an exceedingly obstinate and intractable malady.

The writer was consulted September 14, 1882, by a lady, aged 35, married, and the mother of one child by a former marriage eight years previous, the history of whose case, and physical examination, warranted the conclusion that she was a sufferer from uterine troubles, and that the main features of the case were expressed, in part at least, by "uterine dyskinesia." It should be stated here that this patient is English by birth and education, and by social position belongs to the middle class, but she has been a resident of this country for the past ten years, and up to the time of her second marriage, some two years ago, she had enjoyed excellent health.

Her symptoms were as follows: deep-seated pain in the region of the ovaries on both sides: one side seeming to be at times the more painful, then the other. These pains were not lancinating in the true sense, but yet they appeared to extend both upward and downward, and at times were so severe that she feared to undertake any exercise in the shape of walking, on account of the prostration they caused. The pain in the back, of which she complained, was for the most part continuous, and was of a dragging character. In the occipital region, the pain of the head was

constant, but she was frequently subject to frontal headaches of the most excruciating character. Her vision was also affected, so that she was unable to read ordinary printed matter for a longer period than a few minutes at a time during the day, but at night even this was impossible, though this latter condition had been present for only a few months. The vertigo from which she suffered was both subjective and objective, and proved a great source of annoyance to her, by reason of the difficulty it caused her in the slight attention necessary to the care of the usual household affairs. The stomach was not entirely free from this general nervous disturbance, and manifested its implication by slight occasional dull pains, more particularly noticeable after eating, but the feeling of nausea was frequent, although vomiting had not occurred. The difficulty in locomotion was prominent and permanent, simply walking a block or two being most painful and laborious, while stooping, or walking up and down stairs, not only caused acute pain referable to the womb itself, but greatly exaggerated all the other pains. This condition of affairs, the various symptoms being somewhat modified in the beginning, but gradually becoming more grave, had been present for more than a year, while during this time she had subjected herself to various forms of treatment, but without any apparent relief. Internal medication had been tried for a time, then electricity had been substituted; a pessary had been worn for a time, but that had been abandoned; and later on she had been informed that there was a polypus in the womb. During the two months previous to coming under my charge, she had been under treatment by local applications to the uterus, the sittings being conducted regularly twice a week.

As might have been expected from the foregoing history, the physical condition afforded little encouragement for immediate relief; and, besides, the season of the year was unfavorable, unless, perchance, she might have been placed in some suitable country locality, where she could have the advantages of pure air and water, and a nourishing diet; but this was out of the question. The negative symptoms naturally coming under observation were, the absence of any history of malaria or specific disease, neither had there been any convulsions, and careful inquiry failed to develop any trace of hysterical phenomena. When it is added that the menses were regular as to number, but sometimes a few days earlier, and again a few days later, and that physical examination discovered a slight retroflexion

of the uterus, together with some deflexion of the body towards the left iliac fossa, the description is complete, and the case stated.

In order the more completely to fortify the diagnosis, it may not be uninteresting to quote further from Dr. Hewitt, as follows: "Uterine dyskinesia is one of the earliest symptoms of uterine flexion, and as such it is a symptom which has an extreme importance."

"Further analysis renders it evident that there are two possible reasons for the circumstance that uterine flexions give rise to uterine dyskinesia. The existing flexion is always accompanied by more or less congestion, distension of the uterine tissues, and compression of certain other portions. On the whole, evidence is in favor of the conclusion that it is the increased compression of the uterine tissue at the seat of flexion which is the principal cause of the actual pain."

Treatment in these cases must be conducted in such a manner that the patient will not lose hope and become dissatisfied, while the object in view on the part of the physician should be two-fold, to relieve the suffering and conquer the disease. The typical character of this case, the writer concluded, furnished an opportunity of more fully testing the value of a remedy which it is claimed has a physiological indication under such conditions, and as a result, the spinal hot-water bag was ordered. Dr. Chapman says of the application of heat to the spine (*Handbook of Therapeutics*, Ringer, page 79, 7th ed.):

"1st. The temperature of the sympathetic ganglia being raised, the flow of blood to them becomes more copious, and the functions consequently become more energetic than before.

"2d. Their nervous influence passes in fuller and more powerful streams along the nerves emerging from them, and ramifying over the blood-vessels which they control.

"3d. The muscular bands surrounding those vessels, stimulated by this increased nervous afflux to contract with more than their usual force, diminish proportionally the diameter of the vessels themselves.

"4th. The diameter of the vessels being thus lessened, the blood flows through them in less volume and with less rapidity than before: indeed, it is probable that, while the nervous ganglia in question are made to emit their maximum of energy, many of the terminal branches of the blood-vessels acted upon become completely closed."

Instructions were given that the hot-water bag should be used but once in the twenty-four

hours, and that hot water should also be used morning and evening as a vaginal injection, the patient being cautioned as to the most approved method of using the syringe; her bed was to be so arranged that the buttocks would be slightly elevated, and she was advised to lie either on the right side or in the prone position. In ancient times, when it was believed that the womb was distorted, or out of position, the practice of hanging the patient up by the heels was sometimes indulged in, but modern methods have substituted for that, the less heroic, but more scientific plan of the knee-chest position. In this case, however, reliance was placed in the hot water, no medicine whatever being given, and she was requested to report again at the end of a week.

My surprise and gratification may be imagined, when, on the next visit, she stated that she was about well, and that her troubles had disappeared as if by magic. She could now read with comfort; the pain in the occiput had vanished; the frontal headache was no more, while the pains in the back and groin were so lessened that she could walk without difficulty.

On the 22d of September she was placed on the syrup of the iodide of iron, dr. ss., the iodide of potassium, gr. v., this amount to be taken four times daily, the hot-water treatment in the meantime to be kept up. The object of this treatment was to remove any products of inflammation, and at the same time improve the nutrition of the body. At the end of another week she reported that the improvement continued, and that her strength was gaining. The uterus at this time was still large, "congested" or "distended," but was not hard or tender to the touch; and, without entering into a detailed description of the physiological action of the ingredients composing it, the following prescription was written:

R.	Ext. cimicifugæ,	f. $\frac{3}{4}$ ij.
	Ext. hamamelis,	f. $\frac{3}{4}$ ss.
	Ext. cocœ,	f. $\frac{3}{4}$ j.

M. Sig.—A teaspoonful about an hour after each meal.

This was ordered to be continued for a week, but in a few days she reported that the medicine did not seem to agree with her; so the dose was reduced to one-third of the quantity above stated, with the request that it should be increased as fast as possible until the prescribed amount was reached. The result was that in the course of a few days drachm doses were comfortably borne. On the 12th of October, she was again placed on the iodide of potassium and iron mixture, a sufficient quantity being ordered to last a week. The hot

water was discontinued entirely, and she was asked to come again in about two weeks, thus allowing her to be free from the influence of medicine at least a week before her final visit. At the time of the visit just mentioned above, the patient complained of dyspareunia, and it was then developed that she had also suffered from this complication, which is regarded as a common occurrence in cases of flexion. For this, the compound tincture of iodine was applied freely to the vaginal surface of the cervix uteri, followed by a pledget of cotton-wool saturated in glycerine.

On the first of November this lady came to my office apparently in the best health and spirits, and reported that she had never felt better in her life. Such, then, is the history of a single case which has been watched with more than usual interest; and it is placed before the profession, not as a discovery, but as a practical and rational method of accomplishing desired results. Much could be said of the physiological effects of this remedy, and its congener, ice, but it does not come within the scope of this paper.

DEAFNESS FROM THE USE OF QUININE.

BY M. LANDESBURG, M. D.,
of Philadelphia.

CASE 1. Miss C., a stout, but somewhat anæmic lady, was under my treatment for serous iridochoroiditis of both eyes. In the course of the treatment I ordered her three grains of sulphate of quinine, with five grains of lactate of iron pro dosi, to be taken three times a day. Contrary to my expectations, Miss C. appeared the next morning in my office with the complaint of having become "stone deaf," as she expressed herself, to all appearances in consequence of the use of the powders I had prescribed her. She had never before suffered from any ear-trouble, and her hearing had always been very fine. Shortly after the ingestion of the second powder, she had felt some dizziness and fullness in her ears; she cannot tell that her hearing had diminished, but she had the sensation as if the voices she heard were husky and came from far off. She compared the sensation to that of having the ears filled with water and hearing people speaking. In the course of the afternoon slight headaches set in, and the hearing diminished considerably. Before bedtime, she took the third powder, and awoke the next morning, after a night of sound sleep, unable to understand the voice of her sister, who was her bed-companion. The head was absolutely free, and there was no other trouble but the sensation of fullness in the ears.

Examination showed: External appearance of the ears and of the drum-membrane perfectly normal. With the right ear the patient hears medium loud voice close by; with the left ear she hears whispering close by. The ticking of my watch is not heard when applied to either auricle, but it is heard when pressed against the forehead, the temples, or put between the teeth. The vibration of the tuning-fork is heard equally well from all parts of the cranium. The Eustachian tubes are permeable, and the drum-membranes normally movable. The pulse and temperature are normal, and patient answers negatively my question whether she had experienced any difficulty of speech, or she had observed any rash or eruption on the skin of her body. Inflation, according to Politzer's method, has no effect upon the condition of fullness in the ears, and does not improve the hearing.

The question was: Whether this high degree of impairment of hearing was the immediate consequence of the ingestion of such small doses of quinine, or whether it was a casual coincidence only?

To bring the question to an issue, I ordered the use of the powders to be discontinued, asking the patient to pay strict attention to any change which might occur in the condition of her ears, and to report the next day her observations. The latter were to the effect that the hearing gradually improved during the day, that towards evening the sensation of fullness in the ears had vanished entirely, and that she had been able in the evening to hear conversation with perfect ease. With either ear she could now hear whispering at 15' distance. The next day the recovery was complete, and patient heard whispering at 35' distance with either ear.

Now, to make the experiment conclusive, I prevailed upon the patient to try again the effects of the powders upon her system, to which she consented the more readily, as she was herself greatly interested in her peculiar case, and liked the idea of enlightening, by her experiments, the dark chapters of our medical science.

After two days' rest, during which the ears remained in a perfectly normal condition, patient took again, in the morning after breakfast, one powder in a capsule. No disagreeable after-effects followed. At one o'clock p. m. she took the second powder. At two o'clock she felt slight dizziness, as if the blood was rushing to the head. The face was slightly flushed, and the pulse was somewhat accelerated. These symptoms rapidly vanished, and were replaced by noises and a sen-

sation of fullness in the ears. At three o'clock she ascertained a decrease in the power of hearing. The ticking of her watch she heard only at 6' distance. This impairment of hearing gradually progressed. At nine o'clock she heard the ticking of her watch only at one foot distance. At this time she took the third powder and went to bed. In the next morning the sensation of fullness in the ears was more pronounced, and she only heard words when spoken close to the auricles.

There was no change in the appearance of her ears. With either ear, whispering was heard close by.

The restitution was complete within two days.

Now, to bring the case to the closest test, patient offered, herself, to try, for the third time, the action of quinine. I very willingly accepted her kind offer, the more so as I did not apprehend any injurious consequences from these experiments.

After eight days of rest, I prescribed to the patient three powders of pure sulphate of quinine, in three-grain doses, to be taken in capsules. The result was as follows: After the first powder, taken at eight o'clock in the morning, patient felt slight dizziness and headache, with the sensation as if the blood was rushing to the head, and as if the face was flushed—which, however, was not the case. At ten o'clock she took the second powder. Half an hour later the sensation of fullness in the ears set in, and the power of hearing rapidly diminished, so that towards evening she heard the ticking of her watch only at 4' distance. At nine o'clock p. m. she took the third powder and went to bed. The sleep was sound. In the next morning the noises in her ears were very troublesome, and my examination showed that patient could hardly hear whispering close by.

The recovery was complete.

CASE 2. Mr. C. came under my treatment for furuncles of his right auditory canal, from the repeated attacks of which he has been suffering for several months. His general health was poor, and his appetite very bad. He complained of sleeplessness and nervousness. There was no history of malaria. The power of hearing was normal in either ear. The affection proper I treated according to the indications. To build up his system, I ordered him a decoct. of cort. chin. rub., which he used with great benefit for two weeks. After this I resorted to a combination of iron with quinine—ferri hydrogenii redacti, and chin. sulphur. ad gr. iij. pro dosi, three times a day. After a three days' use of this remedy, fullness

and ringing in the ears developed, with gradual diminution of the hearing power. Notwithstanding these symptoms, which grew worse every day, patient continued the use of the powders for five days longer, to present himself only at the appointed time. His power of hearing was reduced in either ear to hearing a loud voice close to the auricle. There was no pain, and no change in the condition of either drum-membrane. Inflation of ear, by means of Politzer's air-bag, did not improve hearing, and did not diminish the ringing noises in the ears, which however caused but little discomfort to the patient.

Complete recovery within three days set in spontaneously after the further use of quinine had been discontinued.

After an interval of two weeks, during which time patient had used an iron preparation, I resolved to try again the effects which the ingestion of quinine would have on the hearing of the patient. For this purpose I prescribed to him two doses of sulphate of quinine of ten grains each, with the directions to take one powder in the morning after breakfast, and to watch carefully the effects. If there should be no alteration in the condition of his hearing, patient was advised to take in the evening the second powder. A few hours after patient had taken the first powder, he called on me, complaining of such distressing hammering noises in his ears, and showing such impairment of hearing (he heard only loud voice close to the auricle), that I thought best to refrain from further experiments.

The noises developed about an hour after the ingestion of quinine, and were immediately followed by decrease of the hearing power.

This time also spontaneous recovery was rapid and complete.

POPLITEAL ANEURISM CURED BY DIGITAL AND INSTRUMENTAL COMPRESSION.

BY JOHN L. KING, M. D.,
Of Burg Hill, Ohio.

I wish to report a cure of popliteal aneurism, which I have delayed until now to be certain of its permanency.

Wells A. Fitch, thirty-two years of age, married, a worker at a planing machine, on the 15th of March, 1875, consulted me concerning a "lump back of the knee." Diagnosis, popliteal aneurism. Patient could not touch heel (right) to the ground. Two years previous noticed that the leg became easily tired; never observed the pulsation in the tumor until I called his attention to it. Tried forced flexion, which was abandoned before

twenty-four hours because of pain. Secured a relay of assistants, and tried digital compression of the femoral artery at the distal side of the origin of the profunda femoris for eight days and eight hours, two hundred hours in all, with a slight diminution of size of tumor and bruit, and an appreciable thickening of the wall of the sac. Administered tr. ver. vir., tr. aconite rad., morph. sulph., as required. Advised patient to wait a week, during which I had a compressor made with a semi-circular steel slide and thumb-screw, to which was attached an egg-shaped piece of wood, padded, and covered with chamois skin. Every day the patient adjusted the thumb-screw, so as to compress the femoral after the profunda femoris was given off, for a period of one-half to an hour at a time, until about four hours' compression was made every twenty-four. This was kept up with more or less regularity during April, May, June, and July. Some time in October the aneurismal bruit ceased; the tumor was only about one-half as large as at first, hard and non-elastic. I wish to impress upon my brother practitioners that the time usually given by authors for the cure of aneurism by digital compression is too short. Digital compression should not be so complete as to occlude the artery; tardy circulation is desired and required; it does not preclude the possibility, nor interfere with any subsequent surgical operation. It will even be a benefit, because the foregoing compression will have gradually dilated the collateral vessels, so that when the sudden arrest of circulation takes place in ligation, one element of pain will be modified. You must shift your point of pressure to prevent chafing. Do not be discouraged, even if you do not effect a cure in three months. In my case there has been no return, and the patient considers himself cured.

HOSPITAL REPORTS.

BELLEVUE HOSPITAL, NEW YORK.

CLINIC OF DR. LEWIS A. SAYRE.

Reported for the MEDICAL AND SURGICAL REPORTER, by
Edward Develin, M. D.

Hip Disease Cured.

CASE 1. Female, aged six years. This child was brought to me eight months ago, suffering from hip disease. At that time she was following out the plan of treatment advised by Dr. Hutchison for the cure of this disease; this method had been carried out during the previous eight months, and the disease of the joint was yet making steady progress. Dr. Hutchison claims that the weight of the limb—the foot being raised from

the ground by a high shoe being placed upon the foot of the sound limb—is sufficient to extend the limb and prevent attrition of the articulating surfaces of the diseased bone, and at the same time to overcome the contraction of the muscles; his statement being that from three to four hours' extension during each day would accomplish all that is necessary, and that no reflex action would take place at night.

When this plan was first introduced, I was much pleased at the simplicity of this treatment, and was not slow to test its merits; but the results were unfortunate, and I was compelled to abandon it entirely, the weight of the limb alone being utterly insufficient to prevent the reflex action of the muscles. When the child came to me she was using crutches as well as the shoe.

I at once ordered that the child be placed in bed, and that traction be made upon the limb in the line of the deformity, by means of the weight and pulley, the direction of the extension being changed day by day until the limb was brought perfectly straight.

My long extension splint was then applied, and the child allowed to walk out in the open air; just sufficient extension being made to prevent pressure upon the articulating surfaces, and thus relieve the joint from all pressure.

A few days ago the mother brought the child to me, and I requested her to bring her to the clinic to-day.

(The splint was now removed from the patient.)

We have, as you observe, a shortening of about half an inch of the right leg; this is partly owing to arrest of development, and partly to the absorption of the bone by disease; the figure of the child, however, exclusive of this, is perfect; she is perfectly straight, and there is no bending or tilting of the pelvis, as the result of the psoas and iliac muscles being shortened.

For the past six months there has been no weight upon the head of the femur or upon the acetabulum, the patient being supported by the perineal bands; she has been walking upon the perineum. You now observe that free movement can be made in all directions; and no pain whatever is felt at the joint; there is, however, a little stiffness at the knee, owing to the long confinement of the limb; this can be easily overcome in a short time by manipulation and exercise; the motion of the limb will also be greatly improved by exercise; care, however, must be used for some time, in order that the limb be not used to excess; but as long as there is no ankylosis, it can be restored to its former usefulness; but the shortening will always remain. As the child now stoops down you can observe to what extent the muscles are contracted (the child now stated that it did not hurt her at the hip, but hurt her a little at the knee). By gently exercising these muscles, but never to such a degree as to cause pain, this contraction will be entirely overcome. In this case before you we have a perfect cure of disease of the hip joint; you observe that as I now place this high shoe upon the shortened limb, and which the child had been wearing upon the sound limb, according to the Hutchison treatment, she can walk perfectly well without the splint; there is therefore no necessity for its further application.

There is no need for other treatment than this plan I have adopted for the cure of hip disease; you have seen how, by the application of the long or short splint, the entire weight of the body is borne upon the perineal bands of the instrument; your extension here is very slight—it is so slight in fact that it should be called more properly prevention of pressure upon the diseased parts. Some are under the impression that it is necessary to fasten a heavy weight to the limb and pull all the time, and then call that my method of treatment. It is not so: my treatment is simply to prevent the contact of the diseased surfaces, and when the limb is secured in such a manner, motion can take place even in a diseased joint, without causing pain. But remember that it is useless to attempt to apply this long splint until the limb has been brought perfectly straight, by the means which I have just described.

I do not advise you to endorse any statement I may make to you regarding my plan of treatment until you have proved the same to be true, and if you find the same to be incorrect, denounce it at once. This child has had the night extension applied, and afterwards has worn my long splint; and although the disease is practically well, the limb is shortened owing to the progress the disease had made before coming under my treatment.

CASE 2. Now here is a boy who is afflicted with the same disease, but which had not reached to such an advanced stage as the previous case; this child is now wearing my long splint, which consists of a pelvis belt, two perineal bands, side rod and foot plate; extension being made in the rod by means of a ratchet and key. Every time the diseased limb is placed upon the ground the weight of the body is supported upon the perineal bands; it is an absolute impossibility for the articular surfaces to come into apposition when this splint is worn; at the same time motion can take place within the joint with perfect freedom from pain, although Dr. Agnew in his latest work states that it is an absolute impossibility to construct any instrument that will bear the weight of the body and the limb, without pressing upon the joint. Gentlemen, I do not wish to differ with any one, but duty is the first call to a man taking charge of human life, and particularly to one who is giving instruction to others who are also to take charge of life and disease. Now, as I know positively that my method of treatment is thoroughly effectual and practical, and that under this treatment a large number have recovered with perfect motion at the joint, and are as well to-day as thought the joint had never been affected, and during the treatment of these cases motion was secured at all times, to prove this before you I will now make motion at the hip upon the patient. You observe that we now bring the leg up, and the pelvis remains perfectly straight upon the table showing that the movement is in the joint itself, and here (allowing the foot to fall upon the table), you notice that I can let the limb drop without causing pain, attrition within the joint being so thoroughly prevented.

CASE 3. This child a number of you are familiar with, and have, no doubt, carefully watched the progress of the disease.

About thirteen months ago the patient was brought to the clinic suffering from disease of the

hip joint, but as she was too small at that time to follow the plan of night extension, and afterwards the long splint, it was determined to put the child in the wire cuirass, and there make the extension, which has been carefully followed out by the parents until the present, I, however, having seen her occasionally. Two months ago a large abscess formed at the joint, but on careful examination it proved to be extra-capsular. Aspiration was then resorted to, two ounces of pus being withdrawn. It was then carefully bandaged, and since that time absorption of its remaining contents has taken place, and as you observe, that difficulty is entirely relieved. Owing to the improved condition of the hip, we have now placed the long splint upon her, and although owing to her long confinement in the cuirass and her small size, she is yet unable to walk, you observe, as I place her on the ground and hold her by the hands, she is able to move both limbs without causing her any pain, and that there is no shortening of the limb. This child is now making rapid progress towards recovery and perfect use of that limb; her general health has much improved; and now, with application of this splint, she will soon be able to walk alone and secure the benefit of exercise and fresh air; this, with good diet, will secure perfect health. There is no so-called scrofula in this child.

NOTE.—Three weeks after, the patient was again presented at the clinic, in the best possible health, still wearing the splint, and able to walk a short distance.

CASE 4. This young man whom I now present to you illustrates a remarkable recovery from hip disease; I having at the present time in my office four and a half inches of his right femur.

He was between 6 and 7 years of age at the time, and was brought to me in 1865 in an almost dying condition, having a number of abscesses around the joint. I immediately determined upon excision of the joint, and performed the operation in the hospital. I found the acetabulum was perforated, the caries extending down the neck and embracing the head of the femur. I therefore sawed off the bone below the trochanter minor, and removed some pieces of bone from the acetabulum.

Owing to a law recently passed at that time in New York, which forbade the admittance of patients into the hospital from the neighboring states, I was compelled to place him at a hotel, and, although it incurred great risk to the patient, he was removed accordingly. To effect this in the best possible manner, I placed him in a wire cuirass, the result far exceeding my expectations; for at the present time this young man can run with considerable speed, has perfect flexion of the limb, although, as you observe, he has a perceptible limp; this, however, does not in any way prevent him from following his calling, as he is not compelled to use any artificial aid whatever to assist his gait (at this point the young man ran up the centre aisle of the lecture-room and back, without requiring any more effort than would be called for in any of his more fortunate fellows, and with just as much ease).

Here, (exposing the nates of the man) you will observe this deep cicatrix on the right side, passing from the ilium below the ilio-femoral crease,

is where the largest opening was made; but the marks of the abscesses in the anterior regions he requests to be excused from exposing.

I present this case to you as fully illustrating a cure effected in hip-joint disease, and also the utility of the wire cuirass, in which such cases can be treated and removed with comfort and freedom from danger to the patient from one point to another.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M. M. D.

Asthma.

I now show you again the patient with asthma whom you have seen before (see page 260), and I wish to say a few words about him.

You notice how his chest and neck have become fuller, and the clavicle is more elevated, and almost obliterated from view by reason of the distention of the parts around it; and the superficial veins of the neck are distended, though they do not look as large just now as they have. By auscultation under the clavicle I get coarse, rude, rhonchus sounds, which are produced in the larger tubes, and which entirely mask the normal resonance. Yet if I percuss over this region, I find that there is a very remarkable degree of resonance. There is no dulness here to indicate any condensation of pulmonary tissue, such as you get in pleurisy or pneumonia with effusions into the bronchi. The remarkable resonance here is accounted for by the extensive emphysema which this man has. On examining the chest carefully, you would find the resonance noticeably increased in certain parts, as in the margin of the lungs covering the heart and liver, and at the base of the lungs posteriorly. And if there were less coarse rhonchi due to bronchitis, you would find that there is absence of the respiratory murmur, especially on inspiration, and a prolonged feeble expiratory sound, which is due to the loss of elasticity in the lung tissues from their emphysematous distension; and this was produced by his violent efforts at inspiration. He is also suffering from another result of the emphysema, namely an obstruction in the lungs to the free circulation of the blood which should empty into the right ventricle, for the distension of the air cells in the lungs has caused the obliteration of many of the small blood vessels, and the consequent increased pressure in those remaining results in congestion; and so the right ventricle from over-distension becomes dilated, and then the auricle also; and the resulting obstruction to the return systemic circulation is here manifested by the distended veins in the neck, and the dropsy in the legs and elsewhere. These symptoms were so extreme several days ago that it became necessary to dry-cup the chest and to strengthen the heart's action with digitalis, and then he improved at once. He is now so much relieved that he can lie down in bed and sleep comfortably. The vascular tension has also been relieved by means of diuresis and purging. Recently his urine has contained albumen. This is a useful case for illustrating the mechanics of respiration, and because it has brought to your notice conditions which you will sometimes be called upon to treat.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, March 1, 1883. The President, R. A. Cleemann, M. D., in the chair.

Dr. W. Goodell presented the specimens and reported a case of

Double Enucleation of Uterine Fibroids.

Mrs. B., a Hebrew lady, aged 38, and the mother of five children, the youngest five years old, began early in 1880 to have menorrhagia and difficult micturition. Later, her physician, Dr. A. H. McAdam, discovered a uterine fibroid. In January, 1881, Dr. Goodell was called in to see her. He confirmed the diagnosis and found a fibroid in the anterior wall of the womb, bulging out the anterior lip of the cervix, which was greatly hypertrophied, but not at all enlarging the os. The sound gave a measurement of six inches. As all remedial measures wholly failed, he admitted her into his private hospital, and on February 6th cut into the tumor by means of Adams' subcutaneous saw, and by enucleation removed most of it. A month later the fragment left behind descended low enough to be removed without difficulty. The tumor weighed not quite two pounds. At the time of this last operation a small fibroid was discovered in the posterior wall of the womb, but it was too high up to be attacked. Her convalescence was prompt and her monthly flux became natural. On October 6 the sound gave a measurement of only three inches, and she felt well. But in the following March she again sought his advice for a return of the menorrhagia. A fibroid was now bulging out the posterior lip of the cervix, but not expanding the os. The uterine cavity measured five inches. As all remedies again failed, enucleation was once more proposed, and on February 28, 1883, the operation was performed for the second time. The posterior lip of the cervix was cut open by the saw without invading the uterine cavity, and after an hour's hard work, a tumor weighing one and a half pounds was taken away in fragments. Several very beautiful and perfect fibroids, as large as a pigeon's egg, were also removed. They were attached to the capsule of the mother tumor merely by loose connective tissue. About a pint of blood was lost during the operation, but after the removal of the tumor the hemorrhage ceased, and the cavity left behind was not tamponed. The patient is doing very well, although the shock was somewhat profound.

In commenting upon this case, Dr. Goodell remarked that the to-and-fro linear movement of the saw made it a very efficient instrument for working in narrow channels, and that it had the further merit of lessening the amount of hemorrhage. He now used no other instrument for incising the capsule of fibroid tumors. The history of this unique case had somewhat shaken his confidence in the operation of enucleation, because since the womb is affected usually with multiple fibroids, some one of these must invariably be left behind, and a second operation may become needful. He believed that in these cases oöphorectomy, a safer and more sure remedy, had a future before it. He had, in fact, performed the

operation four days ago on a lady who was so feeble from prolonged hemorrhage that he did not dare to remove the fibroid by enucleation, which is a more prolonged operation, and attended by a greater loss of blood. She was doing very well indeed. For the same reason, not daring to enucleate, he had early last year removed both ovaries for a bleeding fibroid, but after a remission of several months the hemorrhage returned, and he will probably have to perform enucleation or hysterectomy.

Dr. B. F. Baer inquired if the case in which hemorrhage returned after oöphorectomy was not of the submucous variety. Ought not the operation to be limited to the interstitial and sub-peritoneal varieties, where enucleation is not possible? In one case reported by Dr. Byford, of Chicago, a uterine (sub-mucous) fibroid went on increasing and hemorrhage continued after oöphorectomy.

Dr. Goodell, from *a priori* reasoning, would expect less favorable results in submucous tumors, as they are more like polypi in their characters, and would be more likely to continue to bleed. The case referred to, in which oöphorectomy had failed, was of the submucous type, and could have been removed by division of the mucous membrane and enucleation, had the patient's condition permitted it.

Dr. B. F. Baer narrated the history of a case in which

Induction of Premature Labor for the Relief of Suppression of Urine

Was considered necessary. The case occurred in the practice of Drs. Marcy and Mecray, of Cape May, N. J. About the sixth month of pregnancy a general oedema was noticed, and the urine contained considerable albumen and a few casts. The amount of urine passed diminished rapidly while the proportion of albumen increased, and the patient became weak and anæmic. Every means was tried to increase the quantity of urine, but without avail. Among the remedies used were a wide range of diuretics and hydragogue cathartics with Basham's mixture. A sudden suppression of urine occurred at eight months, and but four ounces were passed in forty-eight hours: this became solid when heated; headache and spots before the eyes were now added to the other symptoms, a grumous discharge from the uterus had been noticed for a week, and convulsions seemed threatening. Dr. Baer was called in consultation, and he agreed with them as to the advisability of inducing premature labor. A No. 9 flexible catheter was warmed and softened, and was after great difficulty introduced between the membranes and the anterior wall of the uterus. The cervix-uteri had been lacerated in a previous labor, and was hard and small. Pains of a natural character followed immediately upon the introduction of the catheter. After some hours the pulse became weak and the patient faint, the os was but slightly opened, and it was considered advisable to administer stimulants, use Barnes' dilators and the Hodge forceps. A dead child was speedily extracted: the latter had been alive in the morning. Four hours after delivery, urine was secreted, and in two days the albumen had entirely disappeared. The patient recovered.

Dr. D. F. Willard reported a case of

Induced Premature Labor Necessitated by great Œdema of the Labia Minora.

The patient, probably over forty years of age, had been married about one year, and was pregnant with her first child. She suffered from headache, her feet and eyelids were swollen, and her urine showed one-sixth albumen and contained casts and blood corpuscles. Basham's mixture, diuretics of every kind, diaphoretics, hot-air baths, hydragogue cathartics, and tonics, were used without a satisfactory result. Digitalis infusion and jaborandi alone gave a very temporary relief. The patient soon after her first visit called attention to the condition of the labia minora, which were found to be enormously swollen, shining, tense, and pitting on pressure. The urine amounted to from fifteen to thirty ounces per day, and steadily decreased in quantity. The œdema of other portions of the body decreased under the use of digitalis, but that of the labia increased. The patient could lie only upon her back, with the knees drawn up and as widely extended as possible; the pain was great and constant. Lancet punctures were made with temporary relief. The patient was steadily failing, her pulse was 150 per minute. An erysipelatous blush made its appearance, and rapidly spread to the abdomen and thighs. Premature extraction of the child offered the only chance, and was at once performed. Gestation had reached eight months. It was a difficult task, as the labia were five inches in depth. Barnes' dilators and the Hodge forceps were used, and delivery accomplished in two hours. The child was dead, and the mother died three hours later.

W. H. H. GUTHENS, Secretary.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, March 8, 1883.

The President, Dr. James Tyson, in the chair.

Dr. Guy Hinsdale exhibited a series of specimens of cancer, involving the stomach, liver, pancreas, rectum, and lung. They were obtained from recent cases at the Episcopal Hospital.

Carl W., æt. 44, was admitted October 23, 1882. He had never been ill before, and his symptoms had been developed during the two weeks previous to admission. His bowels were regular; he had had no vomiting, but had pain at the lower margin of the left ribs, with cough and friction sounds. Cachexia was marked. The abdomen was soft. A tumor was felt in the left hypochondriac region. The spleen was distinctly felt and enlarged.

The tumor increased in size, became more tender, and pain was at times very severe. The patient's appetite was gone, and emaciation was extreme. Twenty-six days after admission death occurred. At the autopsy, fluid was found in the pleural, pericardial, and abdominal cavities. There were old pleuritic adhesions. The roots of the lungs, the base of the left lung adjacent to the diaphragm, and the pleura beneath the ninth and tenth ribs, were found to be the seat of cancerous deposit. The bronchial and thyroid glands were very much hypertrophied, but not cancerous.

The cardiac extremity of the stomach was the seat of an extensive cancer, but the cardiac orifice was not involved, and the mucous membrane

not destroyed. The pyloric end was intact. The pancreas was the seat of cancerous growth. The liver was of a dark, mottled color, and showed numerous metastatic growths in an early stage of development; its weight was five pounds, nine ounces. The spleen was greatly enlarged and the seat of small secondary deposits. Kidneys normal.

Microscopic sections of the thyroid gland showed simple hypertrophy; sections of the metastatic growth in the liver showed scirrhus cancer.

CASE 2. James S., æt. 40, admitted September 28, 1882. During two months previous to admission he had lost forty pounds of flesh; his skin had become very sallow, and vomiting, which at first was occasional, finally occurred after every meal. A tumor was distinctly felt on the left side above the umbilicus; it moved with respiration, and was painful on pressure. Albumen was present in the urine. The patient's mother had died of cancer of the stomach.

After admission, the tumor increased in size, the patient grew weaker, vomiting frequently, and passing clay-colored stools. Death occurred on the thirty-eighth day after admission.

At the autopsy, the heart, lungs, kidneys and spleen were found in a normal condition; the stomach was very much dilated, and contained undigested food. A cancer was found at the pyloric extremity. The walls of the pylorus were very much thickened, and its orifice admitted the thumb with difficulty.

The liver was detached and found to be the seat of four large masses of secondary cancer. Its weight was three pounds, fourteen ounces. The gall duct was unobstructed.

A microscopic section of the growth in the stomach showed scirrhus cancer.

Case 3. Cancer of the Stomach; Gastro-Colic Fistula.

C. W., æt. 66, was admitted June 13, 1882. His health had been good until four months previously, when he vomited some dark bloody matter. Pain was occasional, and occurred after eating. Vomiting had occurred once. Jaundice began three weeks before admission; the skin was dry and the body not much emaciated. Stools regular, but clay-colored. The liver was slightly enlarged. Distinct nodular masses, slightly painful on pressure, could be felt in the epigastric and umbilical regions. The inguinal glands were slightly enlarged; the axillary glands remained normal. There was no cough; a faint low systolic murmur was heard at the aortic cartilages. The urine was dark yellow, sp. gr. 1.010, and contained no albumen. Vomiting, emaciation and jaundice progressed, the tumor increased in size, and death occurred two months after admission.

At the autopsy, a cancer was found at the pylorus. A fistulous opening, large enough to admit the forefinger, was found to exist between the stomach and transverse colon, which were infiltrated by the cancerous deposit and adherent to each other. The calibre of the colon was small. The mucous membrane of the stomach at the seat of disease was ulcerated and ragged. There was no dilatation or hypertrophy of the walls of the organ. The gall-bladder was distended, and both the pancreatic and common bile duct were obliterated. Heart, kidneys, and other organs, showed

nothing very unusual. The mesenteric glands were slightly enlarged. The spleen was small, and its hilus the seat of a hard calcareous plate; the organ was displaced, lying close against the diaphragm, some distance from the chest-wall, accounting for the perfect resonance which had been noted in the splenic region.

Case 4. Rectal Cancer; Colotomy.

John M., æt. 71, was admitted to the hospital October 26, 1882. He had always been healthy until three months previously, when the movements of his bowels became irregular.

The patient suffered from diarrhœa. His urine was albuminous, and contained hyaline casts. He had hydrocele. He denied specific history. Exploration of the rectum revealed a malignant stricture an inch and a half from the anus.

On account of the patient's age, operative measures were not contemplated until after the passages became very difficult, and hiccough and stercoraceous vomiting demanded relief. This was temporarily afforded by the operation of left lateral lithotomy, which was performed by Dr. John H. Packard. Death ensued twenty-four hours later.

At the autopsy the wound was found in good condition; the descending colon was opened about three inches from the point of its bending downwards. An enormous cancer was found involving the rectum and posterior wall of the bladder, and nearly filling the true pelvis. All the other viscera were in good condition. Microscopic sections showed the cancer to be scirrhus.

EDITORIAL DEPARTMENT.

PERISCOPE.

Chemical Diseases of the Brain and Spinal Cord.

At a recent meeting of the West London Medico-Chirurgical Society (*Medical Press and Circular*, December 6, 1882), Dr. Thudichum described the chemical changes of the nerve centres in such diseases as chronic alcoholic infiltration, softening of the brain, locomotor ataxy, and "cerebral glycosuria." No treatment, he contended, was rational in such cases which was not directed to the central nerve lesion; and if that lesion was chemical, the remedy must be chemical also. Locomotor ataxy, he held, was a disease in which took place a gradual destruction of colorless nerve fibres, and a formation of bodies termed amyloid bodies, which gave a reaction similar, but not identical, to that given by starch granules. This amyloid matter was closely related to, perhaps identical with, cellulose. There was no similarity between it and the amyloid degeneration of the liver, which gave rise only to a brown discoloration with iodine. In locomotor ataxy there also might or might not be increase of fibroid tissue. The disease passed from below upwards with varying degrees of rapidity, and he had known death to be produced in the shortest case in one year, in the longest in thirty years. The author then proceeded to describe a body which he had isolated from brain matter, in some quantity, namely, phrenosin. Phrenosin formed about five per cent. of the brain by weight. It contained an alkaloid called sphingosin, a fatty acid, neurostearic acid, and some water. In disintegration of the white matter which took place in such a disease as locomotor ataxy, the cerebrose radical was set free and passed into celluline. As to the phosphorized and nitrogenous principles of nerve matter, these were of three classes. In the first class, the proportion of phosphorus to nitrogen was 1 to 1; in the second class as 1 to 2; in the third class as 2

to 2. The bodies so produced were intimately connected with the production of vital energy. They were formed in every centre of life action, the blood corpuscles included, and a celebrated German philosopher had said there was "no thought without phosphorus." They had an enormous property of becoming colloid by the absorption of water, and became crystalloid again immediately upon the abstraction of water. This powerful attraction for water prevented disintegration. Chronic alcoholic infiltration was to be treated by washing out the alcohol from the tissues by large quantities of water. Natural wines he had found peculiarly useful in this respect. In acute and chronic softening there was accumulation of phosphoric acid and of cholestrin. Lactic acid existed in the brain in the proportion of one-tenth per cent. Its faulty excretion in fevers produced delirium, and it had been said that its accumulation as a result of fatigue produced sleep. In concluding, the author asked his audience to set aside anatomy, and consider the brain as a lump of chemical matter, as a celluloid septum or wall, on one side of which is arterial blood and on the other venous blood and cerebro-spinal fluid. The chemical constituents, if present in proper proportions, by their reaction on each other maintained the organ in a state of health; but if the normal proportion was disturbed, some form of cerebral or spinal disease followed. Dr. Thudichum's paper, which was of great length, was abundantly illustrated by diagrams, specimens, and experiments. It was listened to with marked attention, but it was evident, from the slight discussion to which it gave rise, that it had been too learned and abstruse for most to follow, and the President and one or two other gentlemen expressed a hope that the author would be able to render his doctrine practicable, by pointing out the exact chemical changes which took place in each disease, and the exact chemical agents to be used as remedies.

The Synthesis of Uric Acid.

New Remedies, March, 1883, says: The first organic body ever produced artificially was urea, and one of the latest that has been formed synthetically is uric acid, also a constituent of the urine, but of much more complex construction. The first was accomplished by the late Prof. Wöhler, the last by John Horbaczewski, in the laboratory of Prof. Ludwig, in Vienna. The operation is thus described by him, in the *Berichte der Deutschen Chemischen Gesellschaft*: Pure and finely pulverized glyccol, obtained from hippuric acid, was mixed with ten times its weight of pure urea made from cyanate of ammonia. The mixture was heated rapidly in a flask on a metal box to 200° or 230° C. (392° to 446° Fahr.). The heating was continued until the fusion, which was at first perfectly colorless, became turbid and thick, and of a yellowish-brown color. When cold, the fused mass was dissolved in dilute caustic potash, the solution was supersaturated with chloride of ammonium, and then precipitated by an ammoniacal silver solution, mixed with magnesia mixture. The precipitate, which contains the uric acid, was well washed with ammonia water, and then decomposed with potassium sulphide. After filtering out the precipitate, the filtrate was saturated with hydrochloric acid, and concentrated by evaporation. The crude product that separated on cooling was again dissolved in dilute potash, and the same process twice repeated. The final product was a yellowish-colored crystalline powder, which was washed with alcohol first, then dried, and the sulphur removed with carbon disulphide, and finally washed with ether. The product purified in this way showed all the properties and reactions of uric acid.

1. Under the microscope, the crystals exhibited the forms and characteristics of uric acid, either plates or whetstone-shaped crystals, according to the purity of the preparation.

2. They reduced alkaline copper solution when heated, and the silver solution without heating.

3. They dissolved in concentrated nitric acid with the evolution of brown vapors, and the onion-red residue left by evaporation (murexide test) turned purple with ammonia, violet with potash.

4. They were very slightly soluble in water, acids, alcohol, and ether; but easily soluble in caustic alkalis.

An elementary analysis gave the following result:

	Calculated.	Found.
Carbon	35.72	35.68
Hydrogen	2.38	4.02
Nitrogen	33.33	33.49

The author reserves the privilege of studying more fully the reactions which he communicates.

Malignant Tumor of the Heart.

The *London Medical Record* says that Dr. Manero reports, in the *Gaceta de los Hospitales* of Valencia an interesting case of malignant tumor springing from the cardiac substance, and protruding as a pulsating swelling through the walls of the chest. The patient was, at the time of his death, aged

fifty-one. The first indications of disease appeared four years previously, in the form of constant lacerating pain in the precordial region, without obvious physical signs; in about a year a bulging of the precordial region was noted, with increased pulsation, attributed to dilatation of the ventricle; and this steadily increased, with increasing pain and gradual emaciation. When seen by Dr. Manero, there was a firm pulsating tumor in the precordial region, about the size of a well-developed virgin breast; it was very painful to touch; the skin over it was healthy. On auscultation of the tumor the normal heart-sounds were heard, exaggerated, but not otherwise altered. The pain suffered is described as intense; it seems to have been of the character of that of angina pectoris, and was attended by constant formication in the left shoulder and upper extremity. Death occurred after the patient had been under observation some months, during which time the tumor had steadily grown, without at all involving the skin. No diagnosis seems to have been made during life. On *post mortem* examination, underneath the pectoral muscles, which were themselves healthy, the chest wall was found to be bulged forward. (The exact state of the ribs is not given.) On removing the front of the thorax, the lower and front part of the pericardium was found to be the cause of the thoracic bulging, which is described as forming a hernia through the walls of the chest, an oval opening being caused by erosion of the third, fourth, and fifth costal cartilages, with portions of the corresponding ribs and sternum. Within this hernial sac of the pericardium, the greater portion of the heart was found enormously enlarged, apparently in all its cavities, and presenting on section the appearance of a new growth, with the aspect of a melanotic sarcoma, in consistence for the most part like that of a sebaceous tumor crossed by pigmented bars and lines, and having numerous large and small pigmented deposits. The growth appeared to be highly vascular. The valves, columnæ carneæ, openings, etc., are said to have been hardly distinguishable. It is not stated how much, if any, of the normal heart-structure was left; neither is mention made of any microscopic examination. The latter omission is a very unfortunate one, for such a general invasion of the cardiac substance by sarcoma as that described by Dr. Manero must be extremely rare.

Treatment of Typhoid Fever in Ziemssen's Clinic.

From the *Medical Press and Circular*, February 21, 1883, we learn that at the commencement of the disease, if there be constipation, calomel is usually given in doses varying from 0.5 to 1.5 grm. As soon as the temperature in the axilla passes 39.5°C. (103°F.), baths are employed, generally every two or three hours at the temperature of the room, about 15° R. (65°F.). The patient remains sitting in the bath about fifteen minutes, whilst the back, neck, and chest are being constantly bathed with the water, as in this manner the heat is extracted more gradually and the inspirations are rendered deeper. In some cases of already existing or threatened cardiac weakness the baths are omitted altogether, but only rarely, however; but the temperature of it

is raised to 22° to 25° R. (81°—88° F.), and when the patient is in it is gradually reduced some degrees. Some alcohol is given both before and after each bath. If the baths fail to produce a decided effect on the temperature, antipyretics are administered. Rothe's mixture—which consists of acid carbolio and sp. vini ana, 1 grm.; tr. iodi., gtt. x.; tr. aconiti, grm. j.; aq., grm. 50; syr., 10 grm.; ol. menth., gtt. ij., M., and of which a teaspoonful is given hourly—has been extensively employed, but quinine still holds its ground. It is given, not too frequently, in full doses of 15 to 30 grs. every second day. If diarrhœa be profuse, it is checked by the use of starch enemata, to which have been added 20 ℥ of tinct. opii. This latter also serves the purpose of calming the patient, and thus rendering the attendance less laborious, and may be repeated several times in the course of twenty-four hours. The nourishment consists mostly of broths, with yolk of egg and milk. Wine is given from the commencement, the quantity and alcoholic strength mounting with the cardiac weakness. Stokes' mixture and freshly-pressed beef-juice are favorites in the height of the fever, or when collapse is threatened. The diet remains unaltered until the eighth day after the subsidence of the pyrexia, after which easily-digested farinaceous and flesh foods are given; whilst the ordinary sick diet is not returned to until after the lapse of another week.

The Salicylates and Hemorrhages in Enteric Fever.

In the *Brit. Med. Jour.*, Dr. James Ferguson, of Perth, writes: "At the time when salicylic acid and its compounds are receiving so much attention, may the following facts be regarded as at least worthy of statement? Last year, while resident in the infirmary here, I had an opportunity of testing the efficacy of certain drugs as antipyretics in enteric fever. These agents were used successively, each over a group of cases, and included the salicylate of soda. The latter had not been long in use, when an increased frequency of hemorrhages from the bowel raised the question, Could the salicylate be favoring the production of that complication of the malady? Whether it were or not, the suspicion aroused dictated the withdrawal of the salt from use in cases of typhoid. Shortly afterwards, I noticed that a foreign observer had reported the salicylate of bismuth, and, I think, also salicylic acid (though of the latter I cannot be certain, as I am not able now to find the report in question), to cause intestinal and nasal hemorrhages. The subject would not have been revived by me at present, but for the recent experience of my successor in the resident's office of the above-mentioned institution, D. H. McLean Wilson, who joins me in placing the facts before the public. Dr. Wilson, in having recourse to the soda-salt in typhoid, found the same striking frequency of hemorrhages to follow closely. His employment of the agent differed from mine, in that he administered small doses of ten to fifteen grains frequently over the twenty-four hours, while I gave half-drachm or drachm doses at longer intervals apart. In the other respect, however, our experiences have been

so similar as to warrant the facts being brought under notice, so that the important practical question involved may, if possible, be decided by the evidence of a number of observers."

A Peculiar Case.

Dr. H. E. Sargent reports the following case in *The Lancet*, February 10, 1883:

Mrs. B—, aged forty-five, weighing 220 pounds, on May 7th, 1882, fell on a zinc pail, its edge striking the abdomen two inches to the right of, and on a level with the umbilicus. A day or two after the fall a tumor, semi-elastic, with distinct outline, could be traced at the seat of injury. It was only slightly tender, and appeared to have deep-seated attachment. About July 20th the skin over the tumor began to discolor. Poultices were applied, and at the end of another week it commenced to slough. Gradually a black mass was disclosed, revealing the true nature of the tumor, which was evidently a blood-clot. This gradually became enucleated, and in due time was turned out, leaving a chasm in the abdominal wall, four inches wide by three deep. Cotton-wool steeped in carbolized oil was used to plug the cavity from the bottom, which rapidly closed. On July 10th, Dr. Fenwick saw the case with me in consultation. After an exhaustive examination, he accurately diagnosed the nature of the tumor as verified by its subsequent history. The case is interesting from its rarity, and the complete recovery under a strictly expectant plan of treatment, aiding the *vis medicatrix nature*. The fall must have caused muscular rupture at the seat of injury, with subsequent hæmorrhage into the cavity thus formed.

The Pathology of Arsenical Paralysis.

Dr. Jaschke (*L'Abeille Méd.*, January 15, 1883) concludes that the paralysis is of peripheral origin, for the following reasons:

- 1st. On account of its localization in the path of a single nerve, the median peroneal.
- 2d. Because the sensory disturbances, hyperæsthesia and anæsthesia, were confined to the same location.
- 3d. The absence of any special symptom of spinal lesion.
- 4th. The absence of atrophy, in spite of the prolonged duration of the disease, excluding the possibility of anterior poliomyelitis, as it is known that atrophy is much less marked in cases of peripheral lesion than when the disease is of spinal origin.
- 5th. Although the paralysis was strongly marked, recovery occurred, rendering the cases analogous to instances of peripheral facial paralysis.
- 6th. The electric reaction corresponded to that seen in peripheral palsies.
- 7th. The existence of pain on pressure in the affected muscles.

Treatment of Erysipelas by Subcutaneous Injections of Resorcin.

The *Medical Record*, January 15, 1883, says that Dr. T. F. Bogusch reports (*Mediz. Obozr.*, February 1882), four cases of erysipelas which he success-

fully treated by hypodermic injections of a 5 per cent. solution of resorcin (25 grains to one ounce of distilled water). Having marked the margins of redness with ink, he made a number of injections around the whole inflamed region, along the line running outside of the mark, at the distance of about $1\frac{1}{2}$ centimetre. He used for each injection 0.25 cub. c. of the solution, always directing the needle towards the centre of a diseased part. As many as 67, 29, 36, and 70 injections (at points nearly equally distant) were required in various cases to complete an elevated ring around the affected region, resulting from the blending of individual swellings produced by injections. In all cases, the injections completely cut short the further spreading of the inflammatory process, the temperature rapidly lowering to the normal level. No untoward symptoms were caused by this treatment, and no other treatment was used. [In the *London Medical Record*, 1880, pp. 172-3, is to be found Professor Brackett's paper on the excellent results of the abortive treatment of erysipelas by the subcutaneous injections of carbolic acid, which was originally recommended by Professor Hueter.—*Rep.*]

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—One of the most worthy institutions in this city is the Maternity Hospital, 734 South 10th street (formerly the State Hospital for Women and Infants). It has had many prejudices to contend against, but has overcome them by patient work and good results. We take great pleasure in inserting the following extract from its last annual Report:

The experience of ten years has fully satisfied the Board of Governors of the Maternity Hospital that the good it has accomplished has been incalculable. Women saved from death by suicide or by the hands of the abortionist, or saved from becoming professional prostitutes in order to procure the living refused them elsewhere; women returned to their parents, to their former employments, or placed in situations where they are leading honest and industrious lives, are results of which the Governors of the Hospital feel justly proud; and their only regret is that, owing to bitter opposition and insufficient support, they have been so hampered in their work that they have been compelled to refuse assistance to so many.

—The "Gardener's Monthly and Horticulturalist," edited by Mr. Thomas Meehan, and published in this city, is a journal of its kind that we can unhesitatingly recommend to those of our readers interested in the pleasant pastime of gardening.

—The 29th Registration Report of Rhode Island (1881) is a model of accurate compilation. In glancing over its pages, one is struck with the

growing frequency of divorce in that State. Nowadays for every 8 marriages there is one application for the dissolution of the bond—or about that number.

—The Surgeon General, U. S. A., has published a circular at the suggestion of Dr. Bowditch, for the purpose of collecting data to determine the normal standard of size for the various organs at different ages. It contains a large number of facts and directions with a view to securing such information.

—The New York Skin and Cancer Hospital, 243 East 34th street, has published an appeal and statement of facts for more liberal support, the appeal being signed by a large number of distinguished practitioners.

—A reprint on alcohol, from the *Transactions* of the Mississippi State Medical Association, by its President, Dr. B. F. Ward, of Winona, is an unreasoning attack against its use in every form, by a thoroughly prejudiced writer.

—Dr. Charles McIntire, of Easton, Pa., in a paper read before the Academy of Medicine, makes an estimate of the percentage of college-bred men in the medical profession. Of the students now in the medical schools, it does not appear that more than about sixteen per cent. have college degrees.

—The Pacific Medical College, San Francisco, is now called the Cooper Medical College, the name having been changed in accordance with the terms of a bequest. The address on the dedication of the new building, by Prof. Levi C. Lane, makes a neat pamphlet of forty-one pages.

—An interesting plan for studying the position of the stars, so that any person can instruct themselves, can be had by addressing Dr. William F. Thoms, 92 Madison street, New York city.

—Neurastrophia (neurasthenia) as a cause of inebriety is no doubt somewhat frequent, and a study of it by Dr. T. D. Crothers, of Hartford, Conn., is very timely (reprint from the *Alienist and Neurologist*).

Amputation of Arm in a Woman Aged 82.

In the *Practitioner*, Mr. Evans, of Swansea, records a case in which he amputated the forearm of a woman eighty-two years of age, who was suffering from an enormous cancerous tumor of the hand. The wound healed partly by first intention, and in thirteen days the remainder healed by granulation. She recovered without a bad symptom.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

FIBRINOUS COAGULA, A CAUSE OF DEATH AFTER OPERATIONS.

Sir Joseph Fayrer, M. D., (*Lancet*, January 13, 1883,) believes that thrombosis of the pulmonary artery and cardiac clot is a more frequent cause of death than is generally supposed, especially after wounds, operations, or injuries which involve removal of large parts of the body, or much loss of blood and great nervous disturbance. Thrombosis of the pulmonary artery and cardiac clot are neither confined to malarial climates nor to traumatic causes, for under certain conditions of disease and of septicæmia, whether traumatic or otherwise, it may occur everywhere, and not merely as a process of dissolution, but as an independent cause of danger or death, which, without it, would not have happened. In probably no condition is it more likely to occur than in splenic or malarial cachexia, in which the deteriorated condition of the blood-elaborating organs and the impoverished character of the blood are proved by the anæmia, and the tendency to disintegration and death of the tissues which is so often seen.

It is the formation of the fibrinous clots in the cardiac cavities themselves, and particularly on the pulmonic side of the circulation, which is so dangerous to life. It may set in when there is no sign of exhaustion, when repair and nutrition are going on satisfactorily, and within a short time hurry off the patient, whose dead body presents no explanation of the cause of death beyond the presence of a firm, decoloured, adherent clot in the right auricle or ventricle, perhaps extending into the ramification of, or it may be impacted in the entrance to, the pulmonary artery.

I have so far noticed the malady as it occurs in persons who are free from cardiac disease, but that it occurs in them is the more reason why it should happen to those in whom a fatty heart is superadded, especially in a hot, damp, and exhausting climate, or even when the heart, though not itself the subject of fatty degeneration, is loaded with fat, externally, or where there are dilatation, weakened muscular cardiac fibre, and, perchance, pleuritic or pericardiac effusions. In

such persons, indeed, the presence of fibrinous concretions may not be needed to determine a fatal issue. The temperature of a hot, damp night, in May or June (always the time of greatest vital depression), in Calcutta, and the shock or after-effects of an operation, or the depression following an attack of malarial fever, may be sufficient; and the patient, after a short and painful struggle of breathlessness, perishes, notwithstanding every effort to save him. This is very distressing, especially when it occurs to a person who appeared to be recovering; and it becomes a subject of anxious inquiry not only as to how it was caused, but how it may be prevented in others.

CARDIAC CIRRHOSIS.

In a recent memoir, M. Juhel-Rényon describes a special form of myocarditis, in which the valvular apparatus remains in the normal condition from the beginning to the end. This hypertrophic sclerosis of the muscular tissues of the cardiac walls, which might be termed cardiac cirrhosis, is characterized by the abnormal development of the connective tissue of the myocardium, a species of hyperplasia, commencing at the periphery of the arterioles, and gradually encroaching on the muscular substance, which becomes atrophied and is replaced by connective tissue. At the same time that many fibres become atrophied, the heart, as a whole, becomes hypertrophied. It is in the muscular portions of the mitral valve (*columnæ carneæ*, *musculi papillares*) that the degenerative lesions are most marked.

The début of cardiac cirrhosis is very insidious; later on the disease is accompanied by certain symptoms, some permanent, others recurring only at intervals.

Among the first are: 1. Weakness of the heart-beat and pulse, coinciding with increased frequency; sometimes the pulse is at 140, but regular. 2. The existence of progressively increasing cardiac hypertrophy. 3. The absence of any blowing murmur, present only in exceptional cases.

Among the inconstant symptoms may be ranged: Pain in the cardiac region, with its maxi-

mum of intensity in the fifth intercostal space; nocturnal polyuria without albuminuria.

Pulmonary congestion may occur at intervals, affecting particularly the anterior portion of the apex of one lung. Finally, at a more advanced period, all the symptoms of asystole may appear; the usual termination is death.

SYPHILIS IN THE FEMALE.

The "Leçons Cliniques," by M. Fournier on this subject have already passed to a second edition. He treats the subject very fully, commencing with the initial lesion, the chancre, which he considers to be as frequently present in the female as in the male, except in those cases where the disease has been communicated by conception. He, in unison with other distinguished syphilographers, admits the possibility of transmission of syphilis in that manner from husband to wife. In such a case syphilis would be inherited by the child as a constitutional malady, just as scrofula or arthritis is transmitted from the parent to his offspring; and, secondarily, the mother would contract the disease from the child, and not directly from her husband.

Notwithstanding the great authority of M. Fournier on the subject, it appears difficult to admit that the disease can be transmitted in this manner. As is well known, syphilis cannot be transmitted by direct inoculation of the sperm, and again, the primary chancre in the female so often passes unperceived. We have frequently seen M. Fournier himself point it out as a very small abraded spot on the vaginal walls, a lesion which might be very readily passed over by an unskilled observer.

M. Fournier calls particular attention to the muscular weakness in syphilitic women, which is very marked when observations are made with the dynamometer. As regards treatment, he recommends a mercurial course from the beginning, as soon as the diagnosis is definitely fixed: this should be continued with intervals of rest for about two years, and should be followed by a few months' course of iodide of potash.

PARIS HEALTH REPORT.

The report of M. Du Castel on the reigning diseases (maladies regnantes) at Paris, during the second quarter of 1882, has just appeared. The hospital mortality has been considerable—4,256, instead of 3,624 for the corresponding period of 1881. Typhoid fever, diphtheria, and lung affections have been the prime factors in this notable increase in mortality. During the quarter, 378 cases of diphtheria were treated in the hospitals, the mortality increasing from 61 per cent. in 1881 to 70 per cent. In the city there occurred 728 deaths from the malady, a very marked increase from 553 during the same quarter of the preceding year. At the children's hospital, in M. Archambault's service, 14 children contracted the malady in the wards, and 10 of the number died!

The eruptive fevers have not been quite as prevalent as regards variola and scarlatina, but the number of cases of measles has been large. The mortality from measles when contracted in the hospital wards was frightful; out of 19 cases contracted in M. Archambault's service, 14 died!

It was during this quarter that the last epidemic of typhoid fever commenced, the number of admissions into the hospitals doubled, and the deaths from this disease increased from 48 during the corresponding period of the preceding year to 100—in the city, 192 deaths instead of 97.

THE STATE BOARD OF HEALTH.

A pregnant editorial was that in one of our daily papers, which, commenting on the defeat of the bill to create a State Board of Health, said it was "because the bill was badly managed in the Legislature."

Is it not a crying outrage that such an obviously desirable and beneficial institution as a board to look after the health of the people should require any *management* at all?

It should have passed, and at once, simply on its merits.

It would be well for physicians to remind the representatives from their neighborhood that Ohio and Pennsylvania are now the only large States in the Union that have not State Boards of Health,

and to impress the importance of such an institution strongly upon them.

The health of the people constitutes truthfully the wealth of the State, and our law-makers should be plainly taught that we will not submit to trifling when questions affecting our health are concerned.

NOTES AND COMMENTS.

Origin of Bothriocephalus Latus Found in the Pike.

That there are more sources than only pork and beef, lard, etc., from which we derive all the disagreeable parasites that infest our intestines, where they are not satisfied with the undigested food we swallow them in, but wait till the chylus has been formed to enrich themselves by this hardy aliment, and become enabled in this manner to assume those characteristic forms of animal life, which all the different "worms" undergo, when they once have put up their residence in our alimentary canal, is daily proven more. But very recently, only in December of last year, Dr. M. Braun has made a new discovery, which he published in Virchow, art. 83, p. 119. He found in the muscular tissue, the liver, seminal glands, and intestines of the pike, which lives in the fresh-water rivers of the East-Sea provinces of Russia, and in the *Lota vulgaris* regularly, the *bothriocephalus scolex* in rather large numbers, usually twenty to thirty. By careful experiments through the feeding of dogs and cats with the meat of the pike, he found that in the latter animal the same *bothriocephalus latus* (tania) as that of the human being, only a little smaller, developed itself. There is by all means a government inspector necessary to investigate all our food, as the complications in this respect are daily augmented more.

Determination of Salicylic Acid in Milk and Butter.

This acid is often used to preserve these articles, and since a dangerously excessive quantity may be used, the following from the *Bull. de la Soc. Chim. de Paris* will prove valuable:

A. Rémont agitates 20 cc. of the milk with 2 or 3 drops of sulphuric acid in a test-tube. The agitation should be strong enough to break up the clot and form a homogeneous mixture; 20 cc. of ether are poured in, gradually at first, and the whole is shaken up until the ether is emulsified only in part. After standing, 10 cc. of the ethereal solution are decanted into an ordinary

test-tube, having a mark corresponding to a volume of 10 cc. The ether evaporates, leaving a residue of butter, which is boiled with 10 cc. of alcohol at 40%, and is then allowed to cool. We have thus 10 cc. of solution containing all the salicylic acid of an equal volume of milk. It is poured upon a filter, and 5 cc. are received in a graduated tube of 15 mm. in diameter; 2 or 3 drops of ferric chloride (diluted with 100 parts of water) are added, and the intensity of the violet color obtained is compared with that of an analogous liquid prepared from pure milk to which known proportions of sodium salicylate have been added. Butter is examined in a corresponding manner.

A New Operation for Ptoſis.

The *N. Y. Med. Jour.* January 6, 1883, says that Wecker ("Ann. d'Oc.," July-Aug., 1882) describes a new operation for the relief of ptosis. He dissects up an oval flap of skin and orbicular muscle for a space of four or five millimetres in length along the free border of the lid. He then passes a suture through the skin above the eyebrow, about the width of the finger above the superior orbital margin, beneath the skin and muscular tissue, and brings it out at the upper part of the wound, beneath the divided orbicular muscle. He then introduces the needle again beneath the orbicular muscle near the inferior margin of the wound, and brings it out through the middle of the bridge of skin just above ciliary margin. Then, making a bridge of five or six millimetres along the ciliary border of the lid, he passes the needle and suture in a reverse direction, and brings it out just above the eyebrow. A second suture is also introduced, just like the first, and at a centimetre from it. Slight traction suffices to completely close the wound, and the two ends of each suture are then tied over a little roll of kid. The results have been very satisfactory.

Diabetic Balano-posthitis.

M. Oscar Simon attributes this affection to the development of a microscopic fungus between the glans and the prepuce. The elements constituting this parasite are mycelium and spores, but no organs of fructification can be found.

The glucose deposited from the urine, in connection with the natural sebaceous secretion between the glans and prepuce, forms a favorable soil for the vegetation of this species of parasite.

The essential part of treatment, is very strict attention to cleanliness; frequent washing out under the prepuce, etc. Dr. Simon recommends

after each micturition lotions with lukewarm water, containing a small proportion of carbolic acid; the inside of the prepuce to be then covered with the following disinfecting powder:

R.	Zinci oxid.,	℥j.
	Amyli,	℥j.
	Ac. salicylic pulv.,	℥j.
M.		

Salicylic Acid in Soft Chancres and Buboſes.

Autier, *Th. de Paris*, says:

1. The efficacy of salicylic acid in the treatment of soft chancres and of buboes appears to us to be unquestionable. While not an absolute specific, it is, in our opinion, capable of being most advantageously employed.

2. Odorless, only slightly painful in its application, soluble in alcohol and glycerin, and leaving no stain on linen, it is preferable, in these important respects, to most other agents employed for the cure of the above-named affections, while perhaps inferior in certain other particulars to some among its rivals.

3. It may be resorted to in all cases, both when the sores are large and well-exposed, and when they are sloughing extensively, or are reached with difficulty; and it is equally available in private and in hospital practice.

A New Test for Impurities in Chloroform.

From the *Boston Journal of Chemistry* we note that according to Von Ikon, a solution of permanganate of potash is reduced by impure chloroform, but not by the pure article. A solution of 1 gram of permanganate of potash and 10 grams of alcoholic potash solution in 250 grams of water possesses a beautiful violet color, which at once turns green when impure chloroform is mixed with it. Von Ikon purified the chloroform by dissolving the permanganate in the least possible quantity of water, adding 20 grams of potash, and mixing this solution with the chloroform in a large flask, and shaking it from time to time. After a few hours it was decanted, and a fresh solution of permanganate added, and the operation repeated, until the latter retained its color for a few hours. The chloroform was then poured off, and dried with carbonate of potash, and finally distilled.

Extirpation of the Gall Bladder for Chronic Gall-Stones.

From the *Medical Press and Circular*, February 21, 1883, we learn that this operation has been successfully performed by Langenbuch, of Berlin,

on the 15th of July, 1882, upon a man, æt. 43, the urgency of whose symptoms justified the risks of the operation. The details of the case were given in the *Berliner Klin. Wochenschrift*, November 27, up to which date the patient's health had steadily improved. Dr. Langenbuch regards this operation as a safe and justifiable one, since it is easy of performance, and the organ removed is not one the existence of which is necessary to life. The steps of the operation are fully described. He recommends it to be performed only by a practised surgical hand, and under the guarantee of the most rigid antiseptics. If very distended, the gall-bladder may be aspirated, thus preventing the chances of rupture and escape of contents into the abdominal cavity.

The Treatment of Pneumonia.

Prof. Bamsler, of the University of Friburg, Baden, directs his efforts chiefly towards sustaining the patient's strength until the disease leaves him—so he says in a letter to Dr. W. Thornton Parker, (*N. Y. Med. Record*, March 3, 1883). The pyrexia being a chief cause of exhaustion, the endeavor is to keep down the body-heat, which he does by cold baths, wet packing and quinia in 15 to 20 gr. doses, in the evening, or grains 60 to 80 of salicylate of soda within an hour in the middle of the night.

The patient's diet must receive careful attention. See to it that he is sufficiently nourished, as by broths, beef tea, milk, and a half to a pint of light wine, in twenty-four hours.

When there are *pleuritic pains*, an ice bag is applied to the chest.

Restlessness; great pain or diarrhœa, is to be met by morphia or Dover's powder.

If bronchial catarrh is a prominent symptom, ipecacuanha in infusion is administered. He never employs sweet spirits of nitre in pneumonia.

Hydatid Cyst in the Prostate Gland.

At a recent meeting of the Société de Chirurgie, M. Tillaux reported the following interesting case. A man, 43 years of age, presented himself at the hospital, suffering from retention of urine and rectal obstruction.

On local examination, a large tumor was found in the rectum; there was intense pain, which seemed to increase rapidly in intensity. M. Tillaux, considering it to be a liquid collection, made an incision, which was followed by the issue of a large quantity of clear liquid. The following day a small hydatid was found in the discharge, and others appeared for several days after. Hy-

datid cysts occupying the prostate gland itself are of very rare occurrence, but Davaine made mention of such cysts in the cellular tissues about the prostate and other organs of the pelvic cavity.

Synthesis of Salicin.

New Remedies, March, 1883, tells us that by the action of sodium amalgam upon helicin—the oxidation-product of salicin—Lisenko succeeded in reproducing salicin. Michael has tried the same process with artificial helicin, and has likewise succeeded in producing salicin.—*Berichte*, 1882, 1922.

Artificial helicin is prepared (according to Michael, *Am. Chem. Journ.*, 1, 309) by mixing an alcoholic solution of acetochlorhydrose with salicylate of potassium.

Infusion of Chamomile as a Remedy for Infantile Diarrhœa.

Christopher Eliot, M. D., writes, in *The Practitioner* of December, 1882, that he now seldom employs any other remedy than infusion of chamomile (*Anthemis nobilis*) in infantile diarrhœa. It is especially useful for the diarrhœa occurring during dentition, when the stools are many in number, green or slimy, and streaked with blood. Pain or cramp especially indicate its use, and a few doses will quickly calm a fretful child. $\frac{3}{4}$ ss. to $\frac{3}{4}$ j. of the infusion may be given to a child under one year of age, or double that quantity to a child over that age, and it may be repeated thrice or oftener daily, according to the severity of the case.

Solution of Bromide of Arsenic.

It consists of

Arsenious acid	1 part
Carbonate of potash	1 "
Bromine	2 parts.
Distilled water, to make	93 "

Boil the carbonate and the acid with most of the water until dissolved; when cold, add the bromine and water enough to make the prescribed quantity. It is said to improve by age, owing to the combination of the bromine. The dose is one to four drops in water, once or twice daily.

New Remedies tells us that it is intended as a substitute for Fowler's solution, and was first proposed by Dr. Clemens, of Frankfurt am Main.

Administration of Aspidospermine.

This active principle of quebracho bark, which has lately acquired some reputation for the relief of difficult breathing attending asthma, emphysema, phthisis, etc., is given in doses of about

one-third of a grain; the dose of the bark being about half a drachm. Eulenberg gives in the *Medicinal Kalendar* for 1883 the following formula for its exhibition:

Aspidospermine	gr. xv.
Distilled water	fl. $\frac{3}{4}$ iss.
Sulphuric acid	q. s. to make a solution.

M. Dose, 15 minims.

Removal of Stains of Bichromate of Potassium.

New Remedies, March, 1883, says: Those who work in chromic acid or bichromate of potassium are apt to acquire stains of the hand which are both disagreeable and persistent. *The Photographic News* gives the following directions for their removal: Rub the stains with a solution of sulphurous acid, and subsequently wash with distilled or soft water. Or, to a warm, strong solution of hypo-sulphite of soda add a small quantity of sulphuric acid; this may then be used on the stains with similar effect.

Crayon-feu.

This name has been given by Dr. A. Moser, of Paris, to crayons which may be used as moxæ for cauterizing poisoned wounds, bites of rabid dogs, etc. It has a conical shape, and is composed of the following ingredients:

Charcoal	30 parts.
Nitrate of potassium	4 "
Iron, powdered	5 "
Benzoin	1 "
Excipient (acacia, etc.)	q. s.
To be made into forty crayons.	

SPECIAL REPORT.

NO. XII.—OPHTHALMOLOGY.

BY CHAS. S. TURNBULL, M. D.

The Following, from the Progress of Ophthalmology During the First Quarter of the Year 1882, by H.

Magnus, Breslau; C. Horstmann, Berlin; A.

Neiden, Bochum, and others, are of Particular Interest.—Archiv. of Ophthalm., vol. xi., No. 3.

Bull, C. S. *Treatment of facial scars affecting the lids either directly or indirectly.* Trans. Amer. Ophth. Soc., 1881. Bull advises the systematic use of massage, and relates three cases in which this mode of treatment produced good results.

Kümmell. *On stretching of the optic nerve.* Deutsche Med. Wochenschr., 1882, No. 1. The conjunctiva is incised in the lower outer quadrant, between the external and inferior recti, a squint-

hook inserted between them, and passed along the globe; and the optic nerve, felt as a tightly-stretched cord, seized from above; a few strong tractions are then exerted. The connective tissue of the orbit is scarcely irritated at all by the operation. As to the therapeutic results of this procedure, which thus far has been tried in seven cases, nothing can be said as yet.

White, J. A. *A simple way of performing opticociliary neurotomy.* Va. Med. Monthly, Dec., 1881. He makes the incision in the conjunctiva, between the upper and outer recti. A strabismus-hook is then inserted, and under each of these muscles, and by them the eye is pulled down and toward the nose. The wound is then rendered more open by inserting a small lid-elevator under the upper lid of the incision. Through this opening the scissors are introduced, and the nerves divided. The eye is then rotated on its axis by the double hook of Knapp, and the posterior part of the sclerotic is carefully cleaned. He has operated on three cases with success by this method.

Chisolm, J. *A singular case of hostility to the local use of atropia and duboisia; the first causing facial erysipelas—the second, temporary insanity in a patient 70 years of age.* Maryland Med. Jour., Dec. 15, 1881. (Burnett.)

Cuisnier. *Pilocarpine in ocular therapeutics.* Semaine Med., January, 1882, No. 4. The incipient atrophy of the optic nerve. Care must be taken in patients suffering from heart disease or atheromatous degeneration.

Emmert. *Hyoscinum hydroidatum*, A. f. A., vol. xi., 2. Its myotic action is very powerful, and is surpassed by no other remedy. A solution of 0.01:10.0 is sufficient. The conjunctiva bears it well.

Fronmüller. *Poisoning by pilocarpine.* Atropine as an antidote, also homatropine. Memorabilien, vol. ii., 1.

Juhász. *Case of atropine-poisoning, cured by pilocarpine.* Klin. Monatsbl., March.

Lange. *Iodoform in blennorrhæa neonatorum*, Petersburg Med. Wochenschr., 1882, No. 10. Acts injuriously; luxuriating granulations develop upon the conjunctiva, which finally become so extensive as to injure the nutrition of the cornea, and thus favor the development of corneal lesions.

Pajzderski. *The action of iodoform salve in ophthalmology.* Inaug.-Dissert., Greifswalde, 1882. One part of iodoform to fifteen of vaseline. Contra-indicated in iritis. Very useful in clearing up the cornea in serofulous pannus and maculæ corneæ.

Berger. *Remarks on the capsule of the lens.* Centralbl., f. prakt. Augenheilk., Jan., 1882. The

capsule consists of lamellæ, of which the outermost one is connected with the zonula Zinii; the lamellæ are united by a cement which is loosened or dissolved in a solution of permanganate of potash. There are nuclei in the lens-capsule of the fœtus. The lens-capsule may be classed as connective tissue.

Eversbusch. *Comparative studies on the finer structure of the iris.* 1. The anatomical reason of the slit-shaped pupil. First communication, *Zeitschr. für vergleich Augenheilk.*, 1882. 1. The following observations were made on the horse: 1. An uninterrupted muscular layer, as it has been described in man and the rabbit, does not exist in the iris of the horse. There are no arcades as can be shown to exist between the dilatator and sphincter pupillæ in man and the rabbit. The connecting links between the dilatator and sphincter pupillæ are simply muscular bands, the arrangement of which may be best compared to the spokes of a wheel. The oblong shape of the pupil of the horse is explained by the existence of an auxiliary apparatus which is attached to the surface of the lens at points corresponding to the shorter diameter, which might be called *ligamentum inhibitorium* or *triangulare iridis*.

Preiss. *The lymph-spaces of Descemet's membrane, and their connection with the cornea.* At the same time a contribution to the knowledge of the anastomosing corneal cells and their termination on the surface of the endothelium. *Virchow's Arch.*, vol. lxxxvii., 1. On the posterior surface of the cornea a system of tubes (lymph-ducts) can be demonstrated, which lie within the endothelial cells and their immediate substratum. The tubes are connected with the spaces between the endothelial cells and their nuclear membranes, and also with the lacunar spaces.

111. Risley, S. D. *A new trial-glass frame.* *Trans. Amer. Ophth. Soc.*, 1881. Two bars which slide past each other through a wedge-shaped block, have attached to them the two semicircular grooves for holding two lenses, with some hooks by which an additional lens can be added. This arrangement allows of a lateral movement of the lenses amounting to 16 mm., or a pupillary distance varying from 50 to 60 mm. It can be held in the hand by means of a handle, or the ordinary spectacle bows can be attached.

These frames can be had of Ivan Fox, optician, No. 1608 Chestnut street, Philadelphia.

Ehrlich. *On induced fluorescence of the eye.* *Deutsche Med. Wochenschr.*, 1882, Nos. 2-4. Ehrlich recommends subcutaneous injections of

fluorescein for studying the changes of nutrition, which cause very intense phenomena of fluorescence in the eye. He has shown by these experiments that the interior surface of the iris has nothing to do with the reproduction of the aqueous humor, which comes entirely from the posterior chamber. The liquid is not derived from the vitreous by transudation, but is principally secreted by the blood-vessels of the ciliary body. Under normal conditions, the aqueous humor is secreted in an entirely different manner; two centres of secretion exist at the periphery of the iris, an anterior nasal and a temporal one; they throw the liquid with a certain force and in a fixed direction upon the posterior surface of the cornea, after which the stream moves in a horizontal direction. An angle is formed at the point where the currents meet. The secretion of the posterior chamber is widely different from the aqueous humor.

Gradenigo. *Auscultation of the eye.* *Am. d'Otalm.*, vol. x., 6. Three kinds of sounds may be heard on the eye: 1. A muscle-sound, resembling the sound of humming of flying insects. 2. Sounds heard at inspiration and expiration; and due to respiratory organs, as the nose, etc. 3. A sound heard when the muscles contract; it is clearly defined, and can be easily distinguished from the others. (Dantone.)

Kroner. *The perceptions of the new-born.* *Breslauer ärztl. Zeitschr.*, February 18, 1882, No. 4. A new-born child cannot control the motions of the muscles of the eye. There is perception of light. The reflex-arch from the optic nerve to the facial nerve supplying the lid and the branch of the oculomotor nerve supplying the iris is completely developed. In regard to the motion of the eyes, he inclined to think that at birth there is no performed nervous mechanism ready to exercise binocular symmetrical vision.

Pfüger. *The nutrition of the cornea.* *Klin. Monatsbl.*, March. The cornea is not nourished by the aqueous humor, as Knies & Weiss erroneously maintain, but from the conjunctiva and sclera. In general the conjunctiva nourishes the superficial, the sclera the deeper layers of the cornea. Within the cornea the lymph-current flows in a centripetal direction from all points of the periphery, then turns inward, and enters the aqueous humor. No centrifugal counter-current of any consequence from the aqueous humor into the cornea exists.

Schöler and Uthhoff. *The significance of fluorescein for the exchange of liquids in the eye.* *Annual report for 1881.* Berlin, 1882. They came to the following results: 1. Under normal conditions

the iris does not cut off the communication between the anterior and posterior chambers; the aqueous humor being constantly renewed from the latter. 2. A current passing from the vitreous through the zonula or Petit's canal and the iris into the anterior chamber, does not exist. 3. The anterior surface of the iris does not take part in the renewal of the aqueous humor, which is derived from the blood-vessels of the ciliary body and the posterior surface of the iris, the "secretory angle." This current gives rise to Ehrlich's line, which always begins behind the iris, at the edge of the pupil. 4. The secretion from the "angle" does not take place simultaneously over its whole surface. 5. The greater part of the current which exists in the eye flows along the iris, through the pupil into the anterior chamber, a small portion of it going into the lens through Petit's canal and into the vitreous. Vitreous and anterior chamber are therefore not separated from each other. 6. If the fluorescein before its discharge has passed the vascular system of the eye (subcutaneous injection), only a small part of it enters the lens and vitreous, the effect of which soon disappears. If, however, it is injected into the anterior chamber, a large proportion is absorbed by the lens; but when injected into the vitreous, it enters the lens only when it has previously passed into the anterior chamber. 7. The colored fluid is absorbed by the lens from the corticalis toward the nucleus, and disappears in the same order. The innermost parts of the nucleus become colored only after two to three weeks. 8. The vitreous does not participate in the nutrition of the lens, as the latter remains uncolored for days, though the whole vitreous is deeply stained, provided the aqueous humor had not previously become colored. This latter event, after an injection into the vitreous, favored and produced as it is by an increase of tension in the vitreous and a decrease in the anterior chamber, does not take place through physiologically pre-existing paths. 9. Opening the anterior chamber (puncture, sclerotomy, iridectomy) changes both quantity and quality of the fluid discharged from the secretory angle, and in this manner influences the nutrition of the lens and vitreous. 10. The secretion of the aqueous humor is controlled by nervous influence. Division of the cervical branch of the sympathetic nerve, with or without excision of the superior cervical ganglion, causes the appearance of the colored secretion in half the normal time, and decreases the quality of the secreted liquid. The subcutaneous injection of fluorescein is therefore a new method of determining tropho-

neuroses of the eye which thus far could not be diagnosed. Secretory and oculo-pupillary fibres of the sympathetic nerve spring with separate roots from the spinal cord, so there are special secretory nerves for the eye. 11. Intracranial division of the trigeminus hastens, increases, and changes the secretion of the eye still more than division of the cervical branch of the sympathetic nerve. 12. As division of $\frac{3}{4}$ of the nerve in the posterior section of Gasser's ganglion does not alter the secretion in the eye, provided the most medial part be preserved, the secretory fibres must be within the medial fourth.

Schmidt-Rimpler. *The specific reaction of the optic nerve for mechanical irritation.* Centrabl. f. d. med. Wissensch., 1882, No. 1. Direct irritation of the optic nerve with a pear-shaped electrode, in patients whose eyes had recently been enucleated, showed that the optic nerve has a specific reaction, which manifests itself to the patients as a sensation of light.

Häuselmann. *Popular treatise on color perception.* Zurich, 1882, with eight colored plates. For use in academies, high schools, seminaries, trade-schools, and self-instruction of artists and laymen. It is divided into a theoretical and a practical part. The former contains the commonest physiological and physical phenomena; the latter treats of the use of colors in painting. He accepts the evolution of the color sense from the light sense, and advocates educating the color-sense.

Jeffries. *Color-names, color-blindness, and the education of the color-sense in our schools.* Educational International Magazine, vol. ii., 4. March-April, 1882. Advocates the system of Magnus.

Hasner. *Ankyoblepharon filiforme adnatum.* Zeitschrift f. Heilk., vol. ii., p. 429. In a child two days old a thread of skin 1 cm. long, and as thick as a thread, was found stretching from the outer margin of the one lid to the other, which tore on the fourth day. It consisted of neoplastic fibrillary tissue.

Lewkowitsch. *Congenital partial symblepharon.* Klin. Monatsbl. f. Augenheilk., vol. xx., p. 14. In a boy 12 years old a horizontal bridge of mucous membrane without blood-vessels was found, which sprang from the inner surface of the outer canthus, and ended with a fan-shaped insertion on the posterior part of the conjunctiva.

Tosswill. *Ectropion successfully treated by transplantation of skin from the arm.* Mr. Louis Tosswill, of Exeter, reports a case of ectropion, due to an extensive burn which was successfully treated by his method. The eversion of the lids was so extensive before the operation that the

globe was exposed during sleep. This was rectified by the operation, and the transparency of the inflamed and opaque cornea was restored. *Brit. Med. Jour.*, January 7, 1882, p. 9.

Lawson, G. *Ectropium of the upper lid remedied by transplanting a piece of skin from the arm.* The *Lancet*, January, 1882, p. 13. Lawson operated for ectropium by transplanting a piece of skin from the arm, with good result.

Abadie. *Plastic surgery of the eyelids.* *L'Union Med.*, 1882, No. 8, p. 87. In a girl 20 years old an ectropium was formed after an extensive destruction of the skin, the forehead, and the temple by burn. The edge of the lid was freed by a cut 6 cm. long, and a piece of skin taken from the arm transplanted into it, which healed in well. The author advises to keep the transplanted flap warm during the first forty-eight hours.

Rampoldi. *Ann. d'Ottalm.*, vol. xi., p. 31. R. reports a case of *congenital phimosis and ptosis*. The muscles of the lids were completely atrophic.

Teillais. *Elephantiasis of the eye-lids.* *Arch. d'Ophth.*, vol. ii, No. 1, 1882. In a woman 75 years old, a large, fluctuating tumor of both upper lids was found, which hung down upon the cheeks. It contained a serous liquid. Both tumors were excised. The microscopic examination showed reticulated connective tissue, with small and large meshes, atheromatous degeneration of the blood-vessels, marked development of the lymph-vessels, and around them an infiltration of round cells.

Theobald. *What constitutes insufficiency of the internal recti muscles?* *Amer. Jour. Med. Sci.*, April, 1882. T. has found a degree of insufficiency, ascertained by means of the vertical diplopia test, in a large number of eyes where there was no complaint of asthenopia. He is at loss to know where to draw the line between normal and pathological insufficiency. He, therefore, concludes that a very considerable divergence (even of 22° for the vertical line and dot test of Grafe) does not of necessity indicate a pathological insufficiency of the int. recti. (We quite agree with Theobald, and add query No. 2.—C. S. T.)

Stelwag. *Papers on practical ophthalmology.* Comment to the text-book. Vienna, 1882, No. 7. Genuine convergent strabismus must be explained as an excess of convergence, which latter naturally is coördinate to the accommodation practiced to reduce the great strain upon the accommodation; and gradually becomes a habit; this excess of convergence is voluntary, though not practiced from choice. *The result of the squint-operation, in many cases so brilliant, is really not a true cure, but a masking of the affection.*

Tessut. *Recherches sur le mode de cicatrization du tendon après la strabotomie*, *Rec'd Ophth.*, February, 1882. After the tenotomy of a muscle, the end of the tendon again attaches itself to the sclera by means of fibrous bands, more seldom to the conjunctiva. Care should be taken in dividing the tendon of the internal rectus, as the muscle withdraws to a considerable degree.

Boucheron. *De la cure de strabisme convergent, intermittent par les mydriatiques ou les myotiques.* *Arch. d'Ophth.*, vol. ii., 1. Atropine treatment is useful in the beginning of periodic convergent hypermetropic squint, as it paralyzes the accommodation, and thus prevents the tendency toward excessive convergence. The atropine cannot be dispensed with, until not even a momentary strabismus is apparent when looking at an object held close. Glasses completely correcting the hypermetropia should then be worn. Eserine may be given at the end of the atropine treatment, and in those rare cases in which convergence increases under mydriatics.

Morano. *Contributions to the pathology of strabismus.* *Giorn. delle Malatt. degli Occhi.*, vol. v., February, 1882. Convergent squint in a child 20 days old; five days previously a violent catarrh of the lachrymal ducts and the conjunctiva had set in. The squint did not disappear until two months after the inflammation had ceased. The author thinks that an inflammation of Tenon's capsule was the cause.

Coppez. Neuralgia of twenty years' standing cured by stretching of the infra-orbital nerve. *Ann. d'Ocul.*, January-February, 1882, p. 59. A miner of 51 had suffered from neuralgia of the right side of his face for twenty years, which had resisted all remedies. It was cured by stretching the infra-orbital nerve.

Imre. A rare case of osteoma of the orbit. *Centralbl. f. A.*, 1882, p. 41. The author saw an osteoma of the orbit in a woman 62 years old, 8½ cm. long, 6½ cm. thick, and 6 cm. high. It was said to have existed for 42 years, and had so displaced the eye that the cornea was on a level with the corner of the mouth. The tumor was cast off spontaneously after an inflammation which lasted a year. Healing was good, and the eye almost regained its original position.

(To be continued.)

—The milk-thistle is said by Dr. Lessenwitch to be serviceable for the relief of hæmoptysis, he having tried it in five cases, using the tincture in doses of fifteen to twenty drops in a teaspoonful of water every two hours.

CORRESPONDENCE.

Premature Dentition.

EDS. MED. AND SURG. REPORTER:—

A few days since, while making a friendly visit to a patient I attended in confinement five weeks ago, I asked her how her baby was doing. She remarked, "Very well, indeed; it has two teeth." Upon examination of the mouth I found the two lower central incisors perfect and well formed. The mother stated that she first noticed the teeth on the ninth day after her confinement. As she did not have occasion to examine the child's mouth before that time, it may have been born with the teeth; at any rate, the teeth were there when it was nine days old.

The child is a female, well developed, of medium size, and apparently in good health.

Cases in which there have been teeth at birth are very rare. J. Lewis Smith speaks of having met with one or two such instances.

I have frequently observed the size of the fontanelles in these cases of abnormal dentition. In this instance, both fontanelles were well closed.

In a case of retarded dentition seen by me some time ago, (the patient, a boy, twenty-six months of age,) the two upper and two lower central incisors only had appeared, and both fontanelles were as large as they usually are at birth. The boy was of a nervous temperament, ordinary size, and not of scrofulous disposition. I attended this boy during several attacks of sympathetic convulsions, which attacks, the mother informed me, he has had three or four times during the past six months. The gums were in a normal condition, and the convulsions did not seem to be caused by the delayed dentition.

What relationship there can be between dentition and the state of the fontanelles, I cannot see, unless by some means or other it be a too rapid or too slow formation of phosphatic matter in the system.

D. A. HENGST, M. D.

Pittsburgh, Pa.

Veratrum Viride in Eclampsia.

EDS. MED. AND SURG. REPORTER:—

Was called February 5, 1883, at midnight, to attend Mrs. Addie B. T., primipara, and found on my arrival that she had had four convulsions; and I witnessed one of the severest convulsions I ever saw. I found the pulse full and bounding, face flushed, and the lady had complained of excruciating pain in the head, but none at all about the uterus. She was flowing slightly, but the os was not dilated and the parts seemed rigid, with no sign of labor, although she was at term. I gave *fl. ex. veratrum viride* gtt. iv. The pain left the head for the uterus, the pulse became softer, the convulsions ceased, and she was delivered at 6:30 a. m. of a fine healthy girl baby, weighing 8½ lbs. Both mother and child doing well. This patient was quite stout and plethoric, and there was considerable œdema of the limbs and other parts, for which appropriate remedies were given, but the œdema did not entirely disappear until about fifteen days after the labor.

CHAS. FULLER, M. D.

Lincoln, Maine.

Danger in Use of Convallaria.

EDS. MED. AND SURG. REPORTER:—

Noting the increase of the literature on the successful use of this new drug in cardiac disturbances, I secured the *fl. ext. convallaria* of Parke, Davis & Co. But before experimenting with it on human subjects it was fairly tried on animals by hypodermic injections. Two large, well-developed kittens were taken first. The first cat had injected, merely under the skin, 5 drops. The symptoms were, general uneasiness, arching back, rapid oscillation of the eyeballs, and the senses were exalted. The cat uttered a low purr like a mucous rale. It played in a few minutes. The second cat was injected with about 8 drops, and had almost the same symptoms as the first, except that they were highly intensified, and accompanied with more pain. I then gave the first cat 10 drops more. Soon vomiting occurred, with great pain. The cats would cry out. Death quickly closed the scene of the cats.

Eight drops killed one, and fifteen drops killed the other. Another experiment proved that four drops would kill a dog.

It may be that different samples of the *fl. ext.* of convallaria differ or vary in strength. But does this prove to be a safe remedy? Is it not a little dangerous in the hands of the younger members of the profession? It was given a fair trial here, and death is the result. Results are of some importance in medicine. Dr. Taylor, of New York, called our attention to its use in apparently heroic doses. He reports giving 3 ij., t. i. d.

It does seem that such heroic use of such a dangerous drug will bring it into disrepute by imprudent and rash administration. It will tend to dismiss the drug before time is given to test its real utility.

We hope this will, at least, serve as a warning to some young physicians that it is well to make haste slowly in the use of "new remedies"—yea, to await further proof that convallaria is even an adjuvant to digitalis.

F. B. ROBINSON, M. D.

Grand Rapids, Wisc., March 13, 1883.

[The observations of our correspondent are accurate, but not new. The *National Dispensatory*, pp. 458-9, mentions that convallaria administered hypodermically to small animals arrests the heart in systole, and produces convulsions. It is, of course, well to be cautious in its use, but there does not appear to be any special danger in this remedy.—EDS. REPORTER.]

NEWS AND MISCELLANY.

Errata.

In Dr. Gaston's article in our issue of December 16, 1882, the following corrections should be made:

On the first page, second column, and last paragraph, for Lanza read *Souza*, and also on page 677 in second column. On page 675, first column, middle of second paragraph, for connection read *correction*. On page 676, at the bottom of second column, for 29th read 24th. On page 677, first column, fifth line from the bottom, for chlorodyne read the word *collodion*.

Hygiene and Sanitary Medicine.

We are informed by a correspondent that *Hygiene and Sanitary Medicine* have formed a part of the curriculum of studies at the American Veterinary College of New York city for a number of years.

Hot Soda.

The *Pacific Medical and Surgical Journal* remarks:

As is well known, hot water cannot be charged with carbonic acid. The so-called "hot soda," which, with coffee or chocolate, with cream and syrups, forms such a palatable drink, is hot water drawn under pressure and in a fine stream through the usual soda apparatus.

Advertising in Lay Journals.

The Irish College of Physicians has followed in the steps of the English College in adopting the following resolution: "That the advertisement of medical books in other than medical publications, and the giving by any of the licentiates, members, and fellows of the college, whether for publication or not, of laudatory certificates of medicinal or other preparations, or medicinal or surgical appliances, is misleading to the public, derogatory to the dignity of the profession, and is censurable by the college."

Regulation of Prostitution in Cleveland.

Regulation of prostitution is to be tested again in Cleveland. Weekly examination of the women in the brothels is to be practised, and women found to be diseased are to be sent to a special hospital, and their property cared for at the expense of the proprietor or owner. In most respects the system adopted there is the same which was tried in St. Louis some years ago. There will be the same opposition and the same difficulties to encounter, and in all probability the result will be a similar failure.

A Stinging Tree.

The *Gardener's Chronicle* gives an interesting account of the effects of the stinging tree, *Laportea gigas*. The pain produced by the sting of a single hair on the right hand gave rise to remarkable symptoms, the pain being confined to the right side of the body and being succeeded by a numbness and slight paralysis. Besides the pain, a sensation of losing the senses, or rather of becoming insane, was experienced. The severe symptoms lasted two hours; the spot pricked remaining constantly painful for nearly a month after being stung.

Post-Mortem Injuries from Insects.

The *Med. Gaz.* calls attention to the injuries resulting from the stings of ants in an actual case (*Pharm. Zeitung*, No. 102, 1881). On the corpse of an infant, which had died from convulsions, considerable injuries, simulating those of an *ante mortem* character, and which might have given rise to a false charge of violence, were observed. It was conclusively proved that the origin of these was due to the action of ants after death, and

formic acid was extracted from the injured portions of the corpse.

Prescribing by Telegraph.

The *Electrician* publishes the following: An employee of the the Eastern Extension Telegraph Company, stationed at Cape Bolimao, Manila, had a narrow escape the other day, having taken 10 grains of sugar of lead in mistake for a similar quantity of ammonia. He telegraphed for advice to the Hong-Kong telegraph office. Dr. Hartigan, of that city, came down to the office, and sent him advice per cable, which resulted in his recovery. The distance between Hong-Kong and Cape Bolimao is about 555 miles. Probably this is the first time that a doctor has prescribed for a patient over 500 miles away from him.

Dead Drunk.

"Dead drunk" is described by savants of the Paris Biological Society to be a condition in which there is a proportion of one part of alcohol to 195 parts of blood in the circulation. Should the proportion ever come to be one part of alcohol to 100 of blood, death would ensue. This might happen, and, in fact, has happened repeatedly, where a very large quantity of alcoholic liquor is swallowed at one time and quickly. In ordinary drinking consciousness is lost, and with it the power to drink more, before the proportion of alcohol in the circulation becomes fatal.

The Association of American Medical Editors.

The next annual meeting of the Association of American Medical Editors will be held in the city of Cleveland, Ohio, simultaneously with that of the American Medical Association, on June 5th and 6th, 1883. The subject of the address to be delivered by the President, Dr. N. S. Davis, Chicago, is "The present status and tendencies of the medical profession and medical journalism." A free discussion upon this important subject is invited, which will be open, not only to members, but to all physicians present. Dr. Marcy's address will be upon the subject of "Journalism devoted to the Protection and Concentration of Medical and Surgical Science in Special Departments."

J. V. SHOEMAKER, M. D., Secretary.

An Incident of Cremation in India.

The *Pall Mall Gaz.* tells us that a few years ago the Babus of Calcutta, hearing about a new cremation apparatus invented in America, called a "public meeting," where the members expatiated on the virtues of the new machine, and subscribed for it on the spot. The order was sent, and in due time came the much-coveted apparatus. The Babus received it with due honors, and placed it in one of the principal burning ghauts. After all the prescribed *sanskars*, they brought the dead body to the machine. But here, for the first time, they became conscious of a slight difficulty—they did not know how to use it! They consulted machinists and sanitary doctors, who pronounced the apparatus perfectly useless for the cremation of a Hindu body with the ceremonies enjoined by the Shastras. Great was the disap-

pointment of the reformers. But they called another meeting, addressed each other in long-winded orations, consulted the authorities, but all to no effect, when—oh happy thought!—"Brothers," said one of the reformers, "the best plan would be to burn dead bodies near the machine when we cannot do so in the machine!" The solution was received with cheers. The machine may be still found adorning the ghaut, and round about it are dead bodies burned in the orthodox fashion. Thus are the gods of Babudom propitiated, and thus the spirit of sanitary reform vindicated!

The Death Lists of New York and Berlin.

Gaillard's Med. Jour. contains the following mortality tables for 1882, received from the authorities of Berlin by Dr. John T. Nagle, making possible a comparison between New York and Berlin in this respect. The population of both cities is nearly equal, that of New York being 1,279,560; of Berlin, 1,174,293. The total number of births in Berlin last year was 44,466; in New York only 27,321 were reported, but the real number was probably about the same as in Berlin. New York recorded 37,924 deaths, outstripping Berlin by more than seven thousand, the number reported there being only 30,465. The infant mortality was strangely alike; of children over five years 17,520 died in New York and 17,266 in Berlin. As to the diseases that were most fatal, the following table will show some suggestive facts:

	New York.*	Berlin.
Smallpox	259	5
Measles	913	144
Scarlet Fever	2,066	604
Diphtheria	1,525	1,914
Croup	729	220
Whooping-cough	658	292
Typhus Fever	65	1
Typhoid Fever	362	356
Phthisis Pulmonalis	5,251	3,791
Pneumonia	3,472	1,823
Bronchitis	1,583	856
Diarrhoeal Diseases	4,050	4,556

Personals.

—The Medical Society of Scott county, Iowa, has elected Dr. Jennie McGowen, a well-known female physician of Davenport, as its president for the ensuing year.

Items.

—Quain's Dictionary—A Warning.—On page 1181, article *Phthisis*, the dose of picrotoxin is given as grain $\frac{1}{6}$ when it should be grain $\frac{1}{60}$.

—"Alcohol," said the professor, "has killed more people than yellow fever." "That is true," said the somewhat bibulous student; "but that is only because more have taken it."

—Frequent micturition, where no special cause appears, is best treated by passing a weak galvanic current from the lumbar region to the region of the bladder.—*British Med. Journal.*

—An extreme opinion of carbolic acid is expressed by Prof. Chandler, of New York. He

says "all the money spent for carbolic acid is practically wasted." Proper plumbing, ventilation, and cleanliness, do the work.

—One physician at Urbana, Ohio, said that another had killed a small-pox patient by mistaking the disease for measles. The retort was that the first accuser had caused a death by something worse than a blunder. Suits for damages are in progress.

—Once it was suggested to the Emperor of Austria that he establish a hospital for fallen women, as is done in London. He is said to have replied that he had not money enough to roof over the whole of Vienna.

—Bitter and nauseous salines are best taken simply diluted with iced water. A mouthful or two of iced water, before and after the dose, to blunt the sense of taste, and the dose between them in a wine-glassful of iced water, renders it easily taken by most persons.—*Squibb's Ephemeris.*

—U. Kreusler, of Bonn, and E. Budge, of Constantinople, have obtained a patent for a mode of preserving rubber goods from hardening and cracking, which consists in steeping them for about a minute in melted paraffin, and drying in a room at a temperature of about 100°.

—In the Société de Biologie, Paris, Rabuteau announced that he had demonstrated in *Cacodyle* properties analogous to curare, and that, in doses considerably elevated, the substance resembled the arsenical compounds in its physiological properties.

—"Have you ever tried the faith cure?" asked a long-haired, sallow-faced stranger, addressing a gentleman who sat behind him in a street-car. "I have," was the answer. "Do you believe in it?" "I do." "May I ask, then, of what you were cured?" "Certainly. I was cured of my faith."

—There are in the four Universities of Switzerland—Basle, Berne, Geneva, and Zürich—a total of 543 medical students, of whom 51 are women. The largest class is at Zürich, where the number is 180. At Berne the number is 164. There are women medical students at all the universities except Basle. At Berne there are 26, at Zürich 17, and at Geneva 8.

—Soak glue in strong vinegar, heat it to boiling, and add to it a quantity of fine flour, until it becomes rather thick. This paste adheres strongly to glass, etc., and may be kept, without spoiling, in a wide-mouthed, glass-stoppered bottle. Should it become too thick, a small quantity may be removed and warmed, when it may be readily applied to paper.

—To make cement for glass: Dissolve 1 part of caoutchouc in 64 parts of chloroform, add 16 parts of finely-powdered mastic, and let the mixture stand in the cold until the mastic is dissolved. If more than the above quantity of caoutchouc is taken, the resulting cement will be more elastic. When using it, it should be applied with a brush to the broken surfaces.

LECTURE.

KOCH AND PASTEUR.

BY PROF. M. DU CAZAL,
Of the Paris Faculty.

GENTLEMEN: In the collection of works published by the German Imperial Sanitary Bureau, in 1881, the researches and discoveries of M. Pasteur were attacked by Koch and his pupils.

Profiting by the occasion offered by the International Medical Congress at Geneva, the French savant replied to these attacks in a communication read before the Congress on September 8, challenging Koch, who was present, to refute his arguments.

M. Koch excused himself, and replied later in a memoir entitled: "On Malignant Charbon Vaccination," which has been reproduced by M. Ricklin in the *Semaine Medicale*.

The *Revue Scientifique* for January 20, 1883, printed a copy of this article, followed by M. Pasteur's reply.

The importance of this polemic and of the questions it raises, merits very careful consideration.

The haughty and aggressive tone assumed in Prof. Koch's memoir is in strange contrast with the wording of M. Pasteur's communication to the Geneva Congress: "Permit me," said he, "to select among those who have opposed my views, the one whose personal ability adds most importance to his opinions; I refer to M. Koch, of Berlin." And again, later on: "In a congress, a universal spirit of conciliation should be the rule; all discussion being courteous, showing the

participants to be animated by high aims, the search of progress, and verity." This appeal for courtesy has, it must be said, received very little attention.

Koch attacks primarily the general method followed by M. Pasteur, which, he says, has many defects: "At the period of his researches on malignant charbon, M. Pasteur found much already prepared. The bacillus of charbon was already known, and the proof that it was the primary cause of the disease had been already furnished."

Of these two assertions, the first alone is true; it was known that in charbon there existed a species of bacteride: but the rigorous, scientific proof that it was the cause and not the effect of the malady, had not been made. If the *Comptes-Rendus* of the Academie de Medecine for that period are carefully examined, it will be found that when Pasteur laid the proof of this assertion before that body, not only it was felt to be perfectly unprecedented, but many of the members were little prepared to accept such a conclusion. How much eloquence was brought forth by Pasteur to establish the value of his method of successive cultures in vitro outside of the economy, and to convince his adversaries that this twentieth or thirtieth liquid of culture, with which he communicated the charbon disease, no longer contained any of the actual virus and could only contain the bacteride, capable of infinite reproduction, and consequently the primary cause of the disease itself.

Then passing to the works of Pasteur on the *saliva* of rabies, Koch addresses two reproaches to the French savant: first, that he was ignorant of the

fact that the microbe found in the saliva of the child who died of rabies at the Hospital Ste. Eugénie, may be also found in the saliva of persons in good health; secondly, that he was wrong in believing that he communicated a new disease to rabbits inoculated with this virus, for the malady developed was simply septicæmia, already investigated by Coze and Feltz, and later on by Davaine.

Koch, later on, asserts that Pasteur is mistaken in thinking that he communicates a new disease, with the microbe discovered by him in the nasal mucous secretion of a horse with the typhoid fever, for this again is simply septicæmia.

As regards the second point, Pasteur distinctly affirms that the microbe in question develops in the rabbit a new disease, differing from septicæmia and differing widely also from the malady developed by the inoculation of the secretion of the nasal mucous membrane of a horse dead of typhoid fever. He offers to inform Koch on this point, as also on others raised in this discussion, before a commission to be chosen by Koch himself.

On the first point we have already established, in another work (Du Cazal and Zuber, *Du Role Pathogenique des Microbes*) that examination of the *Comptes-Rendus* of the *Académie des Sciences* show that not only Pasteur was aware that the microbe (rabie) in question could be found in the saliva of a person in good health, but also that he was the first to announce the fact to the learned assembly, before Vulpian, and consequently before Sternberg.

"Even admitting," continues Koch, "that inoculation of the nasal secretions of the horse develops in the rabbit an infectious disease, differing from other infectious diseases developed experimentally, I should consider this result of secondary signification, and not of sufficient importance to be communicated as a discovery before an International Congress."

The fact is, that Pasteur mentioned this experiment at the Geneva Congress only in referring to his general method of attenuation of the various varieties of virus; he spoke of the microbe of the saliva (rabie) and of that found in the nasal secretions of the horse, only as examples of this method of attenuation.

Koch is again mistaken when he asserts that Pasteur seeks to assimilate typhoid fever of the horse with that observed in the human subject. He asserts that the microbe kills the rabbit by inducing typhoid fever, and this hardy assertion would seem to have some foundation in the anatomical lesions found after death.

But this is very far from saying that the malady resembles typhoid fever as found in the human subject. Is not Koch, on the other hand, rather daring when he asserts that this disease which kills the rabbit in twenty-four hours cannot be typhoid fever, for he is unacquainted with any form of the disease which destroys its victim in so short a space of time?

It is true this malady never proceeds with such rapidity in the human subject; but what do we know of its course in the rabbit?

Later on, Koch again asserts his claim to the discovery of the spores of the charbon bacteride. Koch was incontestably the first to observe the transformation of the charbon bacteride in spores, and this important discovery cleared up many points which up to that period had remained obscure in the etiology of malignant charbon.

But it is none the less true that seven years previously, in his studies on the disease of silkworms, called *flacherie*, Pasteur indicated and sketched out the formation of spores in the pathogenic filaments of this disease, and demonstrated that these spores may become regenerated several years after their formation. This precedent served to lead the way for Koch's discovery, without diminishing in any degree its importance.

Koch again returns to the famous experiment of the artificially-chilled hen (*poule refroidie*) which contracts charbon. The fact itself is not denied, and cannot be; but its interpretation is contested, and in the opinion of the learned Berlin physician, it is not because the hen is chilled, that it is rendered apt to contract charbon; but when the animal is thus nailed on a board and plunged into cold water, the effect on its vital conditions is of such gravity, and the perturbations developed in its system are so intense, that they alone would account for the susceptibility to the action of the virus, without calling up the state of refrigeration as the only cause.

But why invoke these presumed perturbations? Nailed or not, the hen contracts charbon only in a chilled condition. And Koch should have considered the entire experiment as reported in the memoir. He would have learned that if the hen, although already affected and invaded by the micro-organisms, be removed from the water and allowed to become warm, though the other conditions of the experiment remain the same, the animal will recover, and the bacterides disappear from the organism.

The change in temperature alone causes the disappearance of the micro-organisms; and as Pasteur remarks: "It would be extremely satisfac-

tory if all physiological facts were established on equally solid proofs."

Is it necessary also to reconsider the question of the earth-worms, to whom Koch denies the rôle attributed to them by Pasteur, of transporting the infectious charbon germs from deep down in the earth to the surface? We do not consider it necessary, as the recent discussion on the subject in the Académie de Médecine and the report of a commission, appointed to investigate, the truth of his assertions, confirming their exactitude, are yet too fresh to require repetition.

The discussion and report seem to have no effect on the opinions of Koch, whose objections prove but one fact, that the earth-worms do not suffice to explain all the facts in question.

Koch finally arrives at the grand question of the attenuation of the charbon virus, affirming that the honor of its discovery is due to M. Toussaint, and not to Pasteur. And yet he accords that anteriorly M. Pasteur had practiced the artificial attenuation, under the influence of oxygen, of the virus of hen cholera, and that already, after his first researches on attenuated hen cholera, "he had undertaken most important and interesting experiments."

It is certain that, as regards charbon, M. Toussaint made known, before Pasteur, a means of attenuating charbon virus by exposing the infected blood to a certain temperature (56° C.) for ten minutes.

But there was no precision in this method; it might almost be said to be an accident of preparation. Here is the proof: Toussaint thought he destroyed by this means all the bacterides contained in the infected blood; this was an error. The bacterides are not even always destroyed when the blood is submitted to the influence of this temperature for a period of thirty minutes. It was on this account that the savant of Toulouse lost by his vaccinations a variable proportion of the animals inoculated.

It is none the less true, that those who recovered, remained thenceforth refractory to the action of the charbon virus.

The discovery of M. Pasteur, as M. Koch himself admits, is of a different nature. He applied to the study of malignant charbon the same method he had applied in his researches on hen cholera, and discovered a means of treating the virus which may become generalized, in submitting it to the action of oxygen.

By this method may be obtained virus in different degrees of attenuation, and a capital point experience proves, that each one of these states of

attenuated virulence may, conserving its degree of attenuation, be reproduced by culture.

This process, we repeat, has the immense advantage of being a sure, rigorously scientific method, giving always the same results when the experiment is conducted under similar conditions.

This last rule, that to obtain identical results from an experiment it is necessary that it be conducted under exactly identical conditions, appears to be absolutely ignored by the Berlin savant. What should be said of the value of an experiment where he vaccinates mice and guinea-pigs with a charon virus, attenuated sufficiently for the vaccination of sheep? Koch was astonished that they all died of malignant charbon, but it would have been even more astonishing if they had survived.

To follow such a method is to cast aside the primary principles regarding attenuation of virus, a method which allows a proper proportion of attenuation in comparison with the size and vital resistance of the animal to be inoculated.

Koch finally insists at length on the light value which possesses in his opinion the number of animals vaccinated; what is necessary to decide on the value of the method, "is not to know the number, relatively considerable, of animals vaccinated without bad results, but to learn if the preventive inoculation has accomplished its purpose, and the animals have really acquired an immunity from the scourge. On which question Pasteur does not inform us."

But it is not in Pasteur's province to satisfy Koch on this point. If he were to do so, he would be accused of deciding his own case to suit his own views.

The proof required is furnished by M. Boutet in his report to the Société Vétérinaire et Agricole de Chartres. According to his report, in the department of Eure-et-Loire, among the flocks of sheep which were partly vaccinated, the loss among the vaccinated during the year was $\frac{8}{10}$ of 1 per cent. and among the unvaccinated $3\frac{9}{10}$ per cent.

We have not been able to follow very closely the arguments brought forward by Koch, nor the replies of M. Pasteur to each one of the objections made by his adversary; but the following passage from the memoir of the latter will serve to characterize the strange position assumed by M. Koch in this discussion.

"Allow me," writes M. Pasteur, "a short digression. When I refer back, as I do at present, to the researches which occupied my attention from 1856 to 1876—a long space of life before you were born to the scientific world, since your first

work dates from 1876—I find that my unique pre-occupation during this long period was to keep alive microbes in a pure state in appropriate liquids of culture. After all this period of research and labor, is it not astonishing that you lightly accuse me of not knowing how to make pure cultures?"

It is in fact a strange spectacle, implicating a singular forgetfulness of the history of scientific progress—this reproach addressed by a savant of the special competence of M. Koch, to the inventor of this very method of culture of disease germs, which our illustrious compatriot first discovered and utilized in the long and glorious series of his experiments.

COMMUNICATIONS.

GLIMPSES OF SEVENTEENTH CENTURY MEDICINE AND MEDICAL MEN.

BY E. T. BLACKWELL, M. D.

Paterson, N. J.

There is a class of people who decry the present age as compared with the past, and sigh for "the good old times" when civilization and literature and art were believed to have reached the zenith. Whatever there may be of truth in this, as it regards excellence in the fine arts, architecture and eloquence, it cannot be gainsaid that Medicine prior to the discovery of Harvey had little claims to be called a science; so little was then known of Anatomy, Chemistry or *Materia-medica*, and so fanciful and false were the notions of physiology and the etiology of disease. Reference is made in Ziemssen's *Cyclopædia of the Practice of Medicine* to Sylvius, who occupied a most conspicuous position as a leader and teacher of the medical art in the latter part of the seventeenth century, as the first author who had mentioned tubercle as a factor in disease. A fragment of his work on the practice of medicine, published a little over two centuries ago, is now before me: and, as it furnishes a pretty clear exposition of what was then known of the human organism, its diseases and their remedies; and reveals the status of professional feeling and practice, as well as the attitude of the people toward practitioners, and their methods of advancing their knowledge of their art, I judge that some material derived therefrom will interest the reader. So quaint is the style of this book: so incisive and caustic the personal reflections; so simple and hum-drum the expression; so theoretic, and as now believed

false, the most of the etiology; so uncommon and worthless, not to say disgusting, many of the remedies, the reader will relish, I think, rather copious extracts. The title-page here given is full of suggestions:

A
NEW IDEA
OF THE
Practice of Physic;
Written by that Famous
FRANCISCUS DE LE BOE, SYLVIVS;

Late Chief Professor of Physic in the
University of *Leiden*.

THE FIRST BOOK;

of the Diseases either constituting, producing,
or following the Natural Functions
of Man not in Health.

Wherein is containd, beside a New Method
in general, a Vindication of the *Spleen* and
Mother from Fits attributed to them.

As also a new Discovery of Intermittent Fevers,
the *Yellow Jaundice*, and other Diseases,
never before discovered.

All cleared by Anatomical Experiments and
Chymical Demonstrations; as also
by their Cures.

Whereto is prefixed a Preface written by
Dr. Mar. Nedham.

Translated faithfully by RICHARD GOWER,
formerly Student under the Author.

LONDON. Printed for *Brabazon Aylmer*, at
the Three Pigeons in *Cornhill*, 1675.

The dedication, here given, seems to lack nothing in the way of comprehensiveness:

"To all the Supreme Powers in Christian Europe, FRANCISCUS DE LE BOE, SYLVIVS, Physician, wishes Perfect Health of Body and Mind, and also faithful and quiet Peace, from God the giver of every good Gift."

The sub-dedication is to a like effect:

"To the Reader who is studious of Truth and Public Good, *Franciscus De Le Boe, Sylvivus*, wishes Health." This is dated "Leiden, April 14, 1671."

The following notice suggests that literary piracy was well known before the advent of the present age:

To the Gentle Readers and Printers, the admonition of *Franciscus De Le Boe, Sylvivus*: "I would have all admonisht, that I in no wise ac-

knowledge that edition for mine own which Thomas Matthias Gotzius publisht in the year 1664 under my name and of the Colleg of Practicall Physicians: nor that which I hear Frideric Leonardus hath publisht this year 1671 at Paris under the Title of my Practice: much less that infamous and foul Book, which some ill-employ'd busie-body wrote and publisht out of his own wicked Store and impure manners, a few years since, under the Title of the Second Part of Physicall Disputations concerning the Circulation of Seed and the Generation of Man, imitating my stile, whereby he might fasten it upon me, and thereby injure my Reputation."

The translator introduces the work of his "Quondam Tutour" by a dedication: "To the truly Honorable Robert Boyle, Esq."

Dr. Marchamont Nedham supplies a preface of twenty pages to the work, in which he indulges in very trenchant criticisms upon the author, upon medical study, charlatanry, chemical medicines, and the relative merit of Physicians and Chirurgeons, which may be as spicy reading at present as it must have been two hundred years ago. He thus discourses of the author: "He was by Birth a *German*, who through industry arrived to such degree of merit by working and practice at *Amsterdam*, that his Fame spreading about the *Low Countries*, the States of *Holland* cast an eye of great regard upon him, and placed him (though a Stranger) in the Professor's Chair in the Univer-*of Leiden*; which he afterwards adorned for almost thirteen years, by forming many useful Doctrines (not merely formal points of Literature) for the Institution of young Beginners in Physick, of whom a multitude were by his Reputation drawn thither from all parts of *Europe*, to be his Disciples: such Doctrines as have not had their Rise from the Ancients, and the Academies, but most of them from Laboratories of his own and others, wrought out of the Fire for near forty years together, and confirmed by constant Practice among the Sick, in which work of Curing he excelled all his Fellows, in most difficult Cases: Yet because he had recourse mostly to *Chymical Remedies*, (of whose safety and excellency the World is now convinced) the more lazie Tribe of Doctors made it their business most maliciously to calumniate and traduce him, as you will find him miserably complaining in many parts of his Book: of whom he saith in 40th Chapter, that they be ignorant of most Natural Things yet are a prating Crew, that strut about and swell inani Doctorum Titulo, with the vain Title of Doctors, and the World has too many of them; though they and their credit wear off apace."

The methods of getting forward professionally, and the ethics in vogue at the time of this publication, have a special interest in these days of sharp competition and heterodox ethical departures.

Dr. Nedham continues: "To say nothing of their Flatteries of the Great and the Rich, besides the Calumnies that they sow against other Practitioners, the frequentation of Clubs and Tipple to gain Acquaintance, and the glosing collusions and fine Tales with Nurses, Midwives, Women, and Weak People, the Confederacies to cry up one another with *Doctissimo* and *Clarissimo* in Prints, the creating & canvassing of Interests in Families, and the common *chequenerie* of Consultations only with Men of their own Tribe; the most remarkable Trick of all is, that they have an oar in the Boat of every Party round the Town and Nation, having lifted themselves accordingly. Some are for the Church of *England*; some for the Church of *Rome*; some for the *Presbyterian*; some for the *Independent*; some among the Baptised; some for the *Fifth Monarchists*; some for the *Quakers*; every man for himself, and God for all: And so the World is very luckily divided: every Party taking its own Proselyte to be the Ablest, and the most conscientious Doctor. Is not this a short cut (think ye) to get Custom? This and Scholastick Twaddle will do the Work, according to the general Mode of their *Second Commencement*; after which, the Men of no Party, whatever their Industry and Art be, are left to be turned to grass upon the cold common of Integrity."

This period was marked by great activity, and great discoveries in anatomy. Dissection was actively prosecuted, post-mortems were held and vivisection resorted to. That some extra-professional dust may have been raised by this process is possible, and its sinister aspect is thus recorded: "In this latter Age, the great pranks they play are by mounting the Stage of Anatomy, (for that pass 'tis now come to), where many of them are wont ever and anon to make wondrous ostentation of pretended new Discoveries in the little World of Man: with which they have a *Mint* always going, for coining new *Hypotheses*, out of which they start up their various *Dogmaticisms*, to amaze their Admirers, and amuse the World; so that the very Neighbors Dogs are in as much danger of their *Shambles*, as they are of the *Falconers*." Again, "'Tis a common trick among the Tribes of Dissectors, to open Bodies of their own or other Men's Patients, in pretence to satisfie themselves, and the deceased's Kindred touching the cause of Death: and thence they always pick out enough before the admiring By-standers, to justifie them-

selves and their own mistakes, by reasons to prove that the Patient was incurable; or else they will be sure to collect dirty matter enough, to cast upon any Physician whom they envy, whose hap it may have been to have given Physick before them to the same Patient; especially if he be not of their Honorary number: hundreds of able Practitioners and Learned, have been thus artificially blasted: So that it were well if this famous City of *London* would take Notice of such crafty Abuses for the future."

Warning his reader against the dangers of false conclusions drawn from post-mortem appearances, and the theories erected thereon, he says: "No Man can be against a due enquiry into Anatomy, so far as concerns being acquainted with the Structure, Figure, Scituation and Connexion of the Parts of the Body, especially in Cases of Chirurgery, wherein its greatest use doth lie: and of this also it becomes a Physician not to be ignorant, who ought also to be a Chirurgian: though the fine-finger'd Academick Education of Physicians in *England*, hath here unhappily divided the two Faculties, the Professors of the one being brought up to Talk, the other to Work; from whence 'tis observable, we are always furnished with far more able Chirurgians than Physicians. * * * Besides if our Chirurgians were excluded (as that's the desire and aim of the others) from the Practice of Physick, I wonder where his Majesty for his Fleets, and the Merchants for theirs, on which the Wealth and Glory of this Kingdom doth depend, would be supplied with Able Practitioners for the Sick at Sea, the greatest sicknesses, both Acute and Chronick, being there predominant. Not from the fine breed of the *Scholastick Family* whose Learning (so much as it is, and that is in but a very few of them) lies quite beside the way that leads to the more noble Family of Physicians; insomuch that when they first come to Town with the Learned *Cushion-cap* and *Scarlet* the very Apothecaries Boys are able to tutor them in Town-practice, laugh at them, and tell Tales behind their backs. * * * 'Tis to be hoped the Nation will ere long be convinced, that the Laboratory, the Work-house is the way to be traced before we enter the Library, an Apprenticeship from our Youth to work and study under a Practiser, is that only which can make one a Doctor."

Bewailing what he considers misdirection of study, he observes: "The *Materia Medica* lies too much neglected; the improvement whereof is the *one thing necessary*. They ought rather to employ themselves in the Anatomizing of all Natural Subjects, in order to the knowledge of their various

Virtues, by resolving and educing the several Parts and Principles of which they are composed, and in searching out their usefulness by reasoning upon the manner of those Operations by which they are prepared, and from thence calculating what uses they may be put to. * * * How comly would it be, to see them spend their time in making further enquiries into Herbs and Roots which contain innumerable other Virtues than are yet known. Had we not been more beholden to Women and Rusticks, than to the men of Literature, very little more had been known of them now than was a thousand years ago."

"What shall I say," he continues, "of those numerous Treasures lockt up in the Bodies of Stones, Earths, Minerals, Metals, and Salts, which require the Hands of all Mankind to unlock? It were to be wished they would but bestow part of their time and ingeny in reforming the old Doctrines and Notions in Physic, not in substituting new ones drawn from mere *Hypotheses Anatomical*, but from the good old real Principles of *Acre*, *Acidum*, *Salsum*, *Dulce*, *Amarum*, *Ponticum*, *Acerbum*, and *Inspidum*; wherein our *Sylvius* hath here pointed out part of the way, those things being by experience found to be the real principal disturbers of Humane Bodies. The accommodating of Physical Preparations to the qualifying of those when either of them is *peccant*, is the only way."

Dr. Nedham having also written a book, "entitled *Medele Medicine*," which had been sharply criticised by "some small Men of Note," whom he stigmatizes as "incompetent Adversaries," and "Whiffling Novices," who he asserts "were set on by their Fraternity to prepare discourses," against him: and who, whatever else they may have averred, he declares, "added their crafty insinuations that I had printed all Men to have the French Pox. * * * Nor was this all; but the Design was followed up and down by slanderer, that I had used dangerous Medicins in regard I had in that Book magnified the good Effects of Remedies Chymically prepared, and their safety if well made, and their force above all other, in Curation of the most pertinacious deplorable Diseases, of which I have lived to see the World, for the most part, so abundantly convinced, that the more ingenious sort of Mankind have concluded that he who is not well-skill'd in the use of those Remedies, is not worth the name of a Physician."

So determined were the opponents of "Remedies Chymically prepared" that they "were wont in the time of my youth when I first came to Practice exceedingly to decry, and noted with a *black coal* all those that used such Medicins."

His further defence throws considerable light upon the method of dispensing medicines at that time, and will have a living interest for the physician of to-day. "Some years ago," he says, "there was a more ready Opportunity to scandalise me, when my Matter of Medicine being prepared in my own House, was kept private to myself, and so my Adversaries might maliciously say of it what they would: Therefore, as soon as I found the *Company of Apothecaries* had erected a *Laboratory* at their Hall, for supply of their Shops with Medicins of all sorts, of the Chymical Preparation so that a Man might be sure, upon the Publick Stock and Credit of the *Company* to be served with them faithfully prepared, my Heart rose with pleasure to congratulate them in an undertaking so necessary for the Kingdom, it being the Main Matter wherein their Trade was deficient, because what Chymick Medicines were used before to make up the Physicians Prescript, were for the most part bought of *private Operators*; of whom we could have no Confidence for due Preparation, in comparison of what in reason we ought now to have; seeing the Security is grounded upon the Reputation of a Worthy Company of this Honorable City, who cannot be supposed to prevaricate for Profit; seeing what is done this way is by *Common Consent*, which being well managed, will conduce much more to Profit, Reputation and Interest, to each particular Man in his Shop, through the satisfaction which will arise to every Patient, by the benefit which is like to answer the expectations of each Family, from those Medicines rightly prepared. And so, from the time that I observed this, I have eased myself of the Toil I had taken upon me, and wholly referred Patients with Bills, to receive Medicins dispensed by the Apothecaries Hands."

Opposite page one, of the interesting book from which I have so freely quoted, is the following quaint memorandum: "Rob^t Tremills his booke, bought of M^r Sam^l Lorkwood for 12^s and paid him Jan^y 25th 1700, and then all accompts ballanet in his booke: witness is his boy Charles:" which is countersigned, "his boy Charles."

Another autograph is that of Forster Nostrand with this pathetic reminder, "When this you see, remember me." It is dated "Novem. 1st 1786." It has also autographs of Ebenezer Blackly and William Leddell, formerly prominent practitioners of medicine in this upper part of the State of New Jersey. Some account of the Anatomy, Pharmacy, Physiology, Etiology and Practice of Sylvius must be reserved for another paper.

HOSPITAL REPORTS.

THE TREATMENT OF INTERMITTENT FEVER. CATARRHAL INFLAMMATION AT THE APEX OF THE LEFT LUNG. FI- BROID PHTHISIS. PHTHISIS FOLLOWING PNEUMONIA.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL, DECEMBER 20, 1882.

BY JAMES H. HUTCHISON, M. D.,

One of the Attending Physicians to the Pennsylvania Hospital, Physician to the Children's Hospital, Philadelphia, etc.

Reported by WILLIAM H. MORRISON, M. D.

GENTLEMEN: The first patient whom I shall bring before you is one that some of you have seen on a previous occasion. She has been living in the Susquehanna region of this State, and when admitted had for some time been suffering from chills and fever. She exhibited all the signs of marked anæmia—pale face, pale lips and tongue, blowing murmur at the base of the heart, on the left side, and a jugular soufflé. These signs have, under proper treatment, all disappeared.

The treatment consisted in the beginning of the administration of quinine, sixteen grains being taken daily in divided doses, and so given that the whole amount was taken before the hour at which the chill usually occurred. This checked the chills; but we did not stop here. The treatment must be continued for some time. The trouble, especially with dispensary patients, is, that as soon as they are relieved they fail to take the medicine. There is in these cases of intermittent fever a marked disposition for the chill to recur in seven, fourteen, or twenty-one days, or some multiple of the week. It is therefore very important that the medicine should be continued for a week in full doses, and the recourse should be again had to it at the periods when the chill is especially likely to recur. This was done in the present case. Quinine was at first given in full doses, and has been continued in moderate amounts ever since.

While quinia arrests the chills, it is not sufficient in itself to improve the character of the blood. I therefore gave her iron in the form of the tincture of the chloride. I know of no better preparation. It may be given in much larger doses than are set down in the books. In anæmia and erysipelas, I frequently give thirty drops every three hours, without producing any bad effects. The only precautions which it is necessary to observe are to dilute it sufficiently, and to direct that it shall be taken through a tube, in order to prevent its acting upon the teeth. This medicine has another advantage over many of the other forms of iron, in that it is cheap.

The patient has entirely recovered, and I bring her before you simply to show the result of proper treatment in a bad case of intermittent fever.

Catarrhal Inflammation at the Apex of the Left Lung.

This young girl was admitted to the hospital on November 4. She has therefore been in the hos-

pital six weeks. Until I had made a careful examination of the lung, I found no positive indication of disease. Her temperature ranged between 98.5° and 100°. It has never gone above 100°. Careful percussion revealed a slight amount of dullness on the left side under the clavicle, and also above the spine of the scapula on the same side. Very deep inspiration developed a few dry crackling rales. The heart-sounds were also more distinctly heard under the left clavicle than they are in health. There was also some want of expansion. Taking all these symptoms into account, I diagnosed slight catarrh of the upper part of the lung, which may possibly degenerate into phthisis.

I at first placed this patient on Niemeier's pill, which, as you know, contains quinia, digitalis, and opium. This was continued for some time. She has also received cod-liver oil and tonics. For the purpose of checking the night-sweats from which she suffered, atropia, in doses of one-sixtieth of a grain, was given; but as this had no effect, I have lately placed her upon ergotine, three grains being given in a pill at night, and repeated if necessary. Under this treatment, the symptom has slightly improved.

There were in this case symptoms which made me fear the supervention of phthisis, although I am not prepared to say that phthisis is now present. There have been no marked symptoms; she has not had high fever, nor has the pulse been frequent. The following are the only symptoms which have been present; slight dullness at the left apex increased by deep inspiration, increased vocal fremitus, increased distinctness of the sounds of the heart, all indicating that there is some solidification of the lung; but as these are slight, and the patient has, as far as we can make out, no predisposition to phthisis, we may hope that entire recovery will take place.

Fibroid Phthisis.

I shall next bring before you a patient who has been in the hospital for some time, and who, in certain respects, presents features of interest. The history is as follows:

M. A., white, age 45, has been engaged as a servant; she came to this country fourteen years ago; she has never had any children or miscarriages; her mother died when she was five months old; her father was always subject to asthma and "wind dropsy," and died at the age of sixty. She was well until six years ago, when she caught cold and contracted a cough, which is sometimes better and sometimes worse. The menses appeared at the age of fifteen, and have been regular ever since. Three years ago she suffered from dropsy, and at times during the last few years she has had frequent micturition. The urine has been frequently examined for albumen, but none has been found. The specific gravity of the urine is 1018. It is small in quantity and high colored. The dropsy from which she formerly suffered may have been due to either disease of the heart or disease of the kidney. I am disposed to attribute it to an acute affection of the kidney. For the past two and a half years, she has been quite sick. She has lost flesh, and has night sweats. The expectoration is not large in amount, but pretty free in the morning. She was admitted to the hospital on November 14, 1882.

Her temperature has been taken regularly since she has been in the ward, but it has never been more than half a degree above the normal. Since her admission there have been occasional night sweats. The pulse has been regular and only moderately frequent. On superficial examination there seems to be no active disease present at this time. When, however, we examine her carefully, we find marked evidence of disease existing at this time, and also the evidence of previous disease.

On inspecting the chest, it is clear that on the right side the infra-clavicular space is more depressed than on the left. There is also a less amount of movement during respiration on this side. It is sometimes difficult to appreciate slight variations in the amount of movement by the eye; in such cases, you should stand behind the patient and place a hand on each infra-clavicular space. Doing this, I find that the expansion is much more marked on the left side than on the right. The vocal fremitus is much greater under the right clavicle than under the left. The vocal fremitus is normally more distinct on the right than on the left side. The difference in this case is so great that I do not hesitate in saying that, for some reason, the right side is a better conductor of vocal vibrations than the left. The supra-clavicular space of the right side is also more depressed than that on the left.

In percussing this chest, I shall first use immediate percussion. I frequently find this to be the best means of developing dullness when its cause is slight or deep seated. On the right side percussion is dull, but when I strike hard, I bring out a note which has an amphoric character. This is due to the presence of a cavity. There is very little alteration of the percussion note when she holds her breath. As you observe, although the dullness is most marked at the upper part of the right chest, it also extends downward for some distance.

On ausculting the chest in this position I hear a marked blowing sound, which differs entirely from the normal vesicular murmur. It is present in both inspiration and expiration. Inspiration and expiration do not differ much in quality; if anything, expiration is a little softer and of lower pitch than inspiration. When the patient coughs, I hear gurgling. There is then evidence not merely of a cavity, or a dilated bronchial tube, but also of fluid in that cavity. If the cough is at all loud, the resonance transmitted to the ear is very marked. On speaking, the words are transmitted through the chest to the ear. I hear them more distinctly when the patient whispers. This is whispering pectoriloquy, and is of some importance in the diagnosis of a cavity. It is often present when sonorous pectoriloquy is not. This sound is I think best heard through the stethoscope. There are few occasions on which I prefer the stethoscope to the unaided ear. In ausculting the heart sounds, and in making a precise diagnosis of the valve affected, I prefer the stethoscope, and in searching for a cavity it is often of much service. These same signs are found posteriorly. At the base of the right lung there are a few mucous rales, and there is slight dullness on percussion.

There is another sign of some importance in

the diagnosis of this disease, *i. e.*, dislocation of the trachea. In this patient, the trachea is almost behind the claviculo-sternal articulation. The heart in these cases is often displaced. This has not been determined in this patient.

Let me repeat the physical signs which are present in this case: slight flattening under the right clavicle, want of expansion, increased vocal fremitus and resonance, whispering pectoriloquy, cavernous respiration, and on coughing, crackling rales. The same signs are found posteriorly; at the base of the right lung, there is slight dullness and a few mucous rales. On the other side there is no evidence of disease. The respiratory murmur over the left lung is not the ordinary vesicular murmur, but is that which we have when the function of one lung is interfered with. In other words, we have puerile respiration. It has a broncho-vesicular character. Under these circumstances it is rather a sign of health than of disease, for it shows that the lung is attempting to do the work of the other lung.

This patient has never had any marked symptoms. She has never had high fever nor excessive frequency of the pulse. She has, however, a cough, which is not very constant, but which is accompanied in the morning by copious expectoration of purulent liquid. This she says is at times offensive. She also has night sweats.

Let us see if we can explain this condition. Looking back at her history, we find that she has for some time been subject to a cough, which is sometimes better and sometimes worse. We have, therefore, evidence of old disease of the lung. I think that her disease probably originated in a pneumonia which never underwent resolution. All pneumonias do not resolve. Some undergo caseous degeneration, forming a large proportion of the cases of phthisis. Others undergo what is known as fibroid degeneration. In such cases, there is the development of fibroid tissue, similar to that which takes place in cirrhosis of the liver and kidney. This condition is often called cirrhosis of the lung, but this is not a good name; for the word cirrhosis is derived from the Greek word for yellow, and although in cirrhosis of the liver the organ is yellow, the lungs are of this color in fibroid phthisis. Just as an excessive development of fibrous tissue causes a marked derangement of the functions of the liver and kidney, so in the case of the lung, a marked derangement is produced. When this fibrous tissue contracts, it pulls in all directions, and causes dilatation of the bronchial tubes. This accounts for the large amount of expectoration. It is impossible in this case to say positively whether there is only dilatation of a bronchial tube, or whether there is in addition an excavation. My opinion is that there is only an enlarged bronchus. One reason for this opinion is that there is no symptom of hectic fever. If there were a large excavation, we should expect a high degree of fever at night, and sweats. The fact that the expectoration is purulent and sometimes offensive, is rather in favor of an enlarged bronchial tube, at the apex of the right lung. There is also evidence of enlargement elsewhere. I therefore regard this as a case of enlarged bronchial tube accompanying fibroid phthisis, and resulting from chronic pneumonia.

In these cases it is important to keep up the strength. Nutrient remedies, cod-liver oil and tonics, should be given. We have given her these, and as she suffers a little from cough, I have put her upon the use of the following prescription;

R. Acidi sulphurici dil.,
Tinct. opii deodoratæ, āā gtt. iij.
Syr. pruni virginianæ,
Elixir. cinchonæ, āā 3 ss. Misce.

Signa. *

You will find this preparation very efficacious in the cough of phthisis. It is not necessary to give nauseants. I give but a small amount of opium in this prescription, in order to avoid the production of nausea.

In regard to local treatment, are we able to do much by means of inhalations? Local treatment would, I think, result in failure, and might interfere with other remedies. If the expectoration were very offensive, I should resort to some inhalation to correct this. Turpentine is useful for this purpose. The internal administration of turpentine is also at times of service. There has, however, been no marked indication for these remedies, and they therefore have not been used.

Phthisis Following Pneumonia.

This patient is 36 years of age. She was admitted on November 22, 1882. She has had three children; one of these died at birth, and another has died from disease. This rather indicates a scrofulous tendency. The family history is negative. There appears to be no predisposition to phthisis. She has had pneumonia twice; the first time eight years ago, the second time during last June. This is all the history that we have been able to procure.

An examination of the temperature record will show you that the temperature has differed from that of the previous case. When first admitted, the temperature was above normal. Under proper treatment and rest it has diminished, and for some time it has not been more than one-half to two-fifths of a degree above normal. The patient presents the appearance of a person out of health, and a certain amount of anæmia. The face, although usually pale, is at times flushed; sometimes one cheek only is flushed. This shows a certain amount of vaso-motor paralysis. The tongue is œdematous, and shows the marks of the teeth. The pulse is at present frequent, but at times it is not much above the normal.

On percussing the chest, I find some dullness under both clavicles. The percussion seems to produce irritation, causing a cough. In striking the chest, I appreciate a sign which was marked in the other case, but to which I neglected to allude. It is one which the percussor alone can appreciate, *i. e.*, a feeling of increased resistance. Under the clavicles, there is increased resistance, the sound produced is of short duration, high pitch, and deficient in resonance. There is no increased resonance on deep inspiration, showing that the lung does not expand well.

Auscultation reveals harsh respiration of a blowing character, accompanied by numerous rales. The cardiac sounds are transmitted to the ear with increased intensity. The same signs exist on the right side, but are not as marked as

on the left. The vocal resonance is also increased. (The patient was now removed.)

As I cannot in this instance give a very hopeful prognosis, I prefer to speak in the absence of the patient. We have found slight dullness on percussion under both clavicles, increased by full inspiration, increased vocal fremitus and resonance. In addition to these, there are blowing sounds and crackling rales. These indicate not only that there is induration, but also that softening is taking place. We have also a history of two attacks of pneumonia—one several years ago, and the other within the past year. I want at this time to call attention to the fact that there is a form of pneumonia which is apt to degenerate into phthisis. I know that high authorities, as, for instance, Professor Flint, think that phthisis rarely, if ever, results from pneumonia. My experience has led me to form a different conclusion, and to agree with those equally high as authorities, who say that phthisis is often preceded by pneumonia.

The treatment has of course differed somewhat from that of the previous case. On admission, there was fever, temperature of 101° , and frequent pulse. She was placed on the use of Niemeyer's pill, every three hours. Under this treatment the temperature fell, the pulse diminished in frequency, and the other symptoms improved. I then placed her on cod-liver oil, but this disagreed with her, occasioning sickness of stomach. In such cases it will do more harm than good to continue its use. She was then given malt, which she has used with great advantage during the past few weeks. In addition, she has had other remedies, which were prescribed as occasion required. At present, she is taking nothing but malt. She has no cough. There is then no necessity for prescribing the mild cough medicine used in the preceding case. She eats well, sleeps well, and all the symptoms are improving, and I think that in a short time I shall be able to show her to you still more improved. Unfortunately, her condition is such that if she left the hospital and attempted to work, the active symptoms would undoubtedly be reproduced. It will be necessary during the winter to have her in the hospital, or secure her a home where she will be free from work.

MEDICAL SOCIETIES.

ALLEGHENY COUNTY MEDICAL SOCIETY.

The Allegheny County Medical Society met in Common Council Chamber, Pittsburgh, March 20, 1882.

President, Dr. John H. Thomas, in the chair.

Dr. G. B. Fundenberg, from the Committee on *Health and Disease*, presented a written report, devoted mainly to typhoid fever. He reaffirmed the opinion held by most medical men, that the fever germ must pre-exist, and also maintains its identity; that external conditions cannot originate the poison.

The Doctor thinks we can prevent 19 out of every 20 cases. The public must be taught the cause.

There are two avenues by which the poison enters the system,

1. By the air we breathe.
2. By the water we drink.

Bad cases often occur at an elevation of 2,200 feet, as in Somerset county, where the Lector formerly practiced.

In the country and small towns the wells are generally close to the kitchen, and are often badly contaminated by slops, a shallow privy well close at hand, probably a pig-pen, and possibly a manure-pile. An odor arises from all this, and an infection is being continually breathed.

In Pittsburgh, opinion among medical men is divided as to source of the disease; some maintaining that it resides in the water we drink, and predicting a higher rate of mortality from this cause upon the completion of the Davis Island dam. He thinks in Pittsburgh we can generally find the cause in bad plumbing or a contiguous filthy cesspool.

Dr. Hoffman, from the same committee, presented an article on Pertussis, with reference entirely to his method of treatment. His method of treatment is to vaccinate the patient as soon as the disease is well established. As the vaccination develops, the whoop diminishes. He has been pursuing this course for twelve years, with invariably good results. He thinks it will diminish the intensity of the disease in every instance. He has no theory of its mode of action.

Dr. Sutton mentioned that vaccination in pertussis was the method always pursued by the late Dr. Dale, of Allegheny.

Dr. Fundenberg could offer no theory for the mode of action, unless it was the well-known antagonism of germs.

Dr. Batten related a case of Breech Presentation in a Primipara, the coccyx to right acetabulum. Has several times been deceived in breech presentation before the os was well dilated. Thought at first this was head presentation. In this case he delivered mainly by traction, there being no pain. Used finger in point of hip at first, afterwards by tape. Child was born alive.

Dr. James McCann presented for inspection a pathological specimen consisting of a portion of the popliteal artery found above the point where torsion had been made in connection with amputation of the limb, showing formation of clot.

The patient, 40 years of age, was admitted to West Penn Hospital with several injuries, the most important being a lacerated wound of leg, rendering amputation at knee-joint necessary. The amputation was performed with long anterior and short posterior flap. The posterior flap and connective tissue sloughed deep, the whole leg became erysipelatous, and patient died on 18th day without any hemorrhage. Torsion has been the method employed to arrest hemorrhage in the West Penn Hospital, for the past seven years; and the experience of Dr. McCann and his colleagues in the hospital corresponds with that of Bryant. Dr. McCann has performed torsion in the popliteal, tibial, femoral in the middle thigh, brachial and others, with never any secondary hemorrhage. Thinks torsion is always the preferable method of arresting hemorrhage, but the twisting must be done well—must give five or six complete turns with the forceps.

Dr. A. M. Pollock exhibited a model of a fracture bed which had been used in the case of the father of Dr. J. W. Neely, age 76 years, who had sustained a fracture of neck of femur, and was devised by Dr. Neely. The difficulty in these cases is to have movements of the bowels with as little difficulty as possible. This is an ordinary small bed with mattress, with frame around the top, across which strong canvas is stretched and fastened. This framework is fastened at each side of bed by two strips of wood or iron, in such a manner that the top frame and canvas can be raised, pushed a couple of feet towards foot of bed, and held there until mattress can be removed, or as long as necessary; and beneath the canvas, through which is an opening, a vessel can be placed. For it, is claimed simplicity, efficiency, and cheapness.

Drs. Sutton, Huselton, Wallace and McCann stated that they have seen in use practically the same apparatus for ten or twelve years, under the name of the Leisure Fracture bed.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

(Continued from p. 349.)

Case 5. Cancer of the Rectum. Secondary Cancer of the Liver.

Christian H. was admitted July 5, 1882. He was emaciated, weak and cachectic. He stated that for twenty-seven years he had been perfectly well, but that two months previously he had noticed loss of flesh, and about the same time discovered a growth at the anus which was small, but which gave him a great deal of trouble at stool. Two weeks later he noticed that his feet and legs had become swollen, but it was not till his admission to the hospital that he became aware that there was anything the matter with his abdomen. The patient's father probably died of cancer of the stomach.

The anal growth was excised, and proved to be an adenoid type of malignant disease. Vomiting, dyspnoea and sallowiness of the skin increased until his death, five weeks after admission. The autopsy showed that the liver and rectum were the only structures seriously diseased. The liver was enormously enlarged, and filled the whole upper portion of the abdominal cavity. It was slightly adherent to the diaphragm and adjacent viscera, and was studded with cancer nodules varying in size from that of a filbert to that of an egg, often coalescing, and pretty equally distributed over the surface. The whitish color of these nodules was in strong contrast with the dark color of the liver, giving it a variegated appearance. Its weight was 10 pounds, 4½ ounces. The walls of the rectum, six inches from the anus, were infiltrated with the new growth. This was the primary seat of disease. The secondary growth was very rapid, almost entirely painless in itself, and disturbing the patient only by mechanical irritation of the stomach, and the production of oedema and ascites by interference with the circulation. Jaundice did not occur.

Microscopic sections of the anal growth revealed an adenoid growth resembling an aggregation of Lieberkuhn's crypts. It was an example of an early involvement of the part. The growth higher up in the rectum was more advanced, and

illustrated the encephaloid form of the disease. A section from the metastatic deposit in the liver showed a stroma of fibrous tissue with alveoli, lined by epithelial cells, the peripheral cells retaining their columnar shape. It was an example of the reproduction in the liver of the same follicles found in the primary disease of the rectum.

An Unique Specimen of Ossification at the Aortic Orifice.

Exhibited by Dr. J. T. Eskridge.

It was sent him from a distance, and consisted of about one inch of the cardiac end of the thoracic aorta, the aortic semi-lunar valves, and the immediate portion of the heart. The specimen was removed from a man who, aged about seventy, had suffered a number of years from severe heart disease. The walls of the large arteries were thickened, rigid, and contained numerous deposits of inorganic matter. The left ventricle was enormously enlarged. He was unable to obtain any information with regard to the condition of the cardiac valves, other than those of the aortic orifice.

Description of the specimen.—The aorta, where it surrounds the valves for about half an inch in extent, is a hard, unyielding substance of fibrous tissue, and calcified and ossified tissue-matter. The valves in several places are about one-fourth of an inch thick, and seem to have been almost entirely transformed into bone-like material. They are rigid and immovable, and have almost completely cut off all communication between the heart and aorta. One of the leaflets, about three-fourths of an inch in all directions with its vegetations, stretches across the aorta, lies against and is apparently adherent to the other segments of the valves, the latter being curled upon themselves. The central portion of the aorta is entirely occluded, and only two small openings through which the blood could have escaped from the left ventricle are seen between the valvular leaflets near their peripheral attachments. The larger of these holes admits a flattened probe three mm. wide by one thick; the smaller is about two-thirds as large. Three other smaller orifices have existed, but these were obliterated before death by a thin, fibrous, transparent membrane, which is still seen. The valves on the cardiac side are tolerably smooth, but on the aortic side they are very rough, one of the leaflets supporting a vegetation, 10 mm. long. One of the segments of the valves is adherent to the inner coat of the aorta for about half an inch in extent, the free end of the valve being folded upon itself, and pointing toward the nearly closed aortic orifice. After macerating the specimen in water for forty-eight hours, the diseased valves still remain inflexible. Drs. Formad, Dunn, Griffith and Edwards reported having similar, or nearly similar cases. Drs. Tyson and Nancrede called in question the correctness of calling the disease *ossification* of the valves, as it was in reality a *calcification*. Dr. Shakespeare concurred in this view, and thought that ossification rarely, if ever, occurred in this situation.

Dr. Eskridge said that Hayden (Diseases of the Heart and Aorta, vol. ii., p. 839), referred to bony deposits in the aorta and its valves, as follows: Sir Dominic Corrigan exhibited before the Pathological Society, of Dublin, (see Proceedings, vol. ii.

new series, Feb. 1864), the heart of a young woman, in which the root of the aorta had undergone complete osteoid transformation; it was likewise greatly dilated, and the aortic valves had been rendered thereby inadequate. During the patient's last illness, a systolic murmur of metallic quality, appropriately designated a "trumpet-bruit," was audible at the base, and in the ascending aorta and carotid arteries; there was likewise a soft diastolic murmur. He regards a "trumpet-bruit" as absolutely diagnostic of bony deposit in the aorta, either in the form of a "rim of bone," or a "projection or tongue of bone." In the same paragraph, Corrigan refers to Dr. Banks' specimen of "a tongue of bone" projecting into the aortic orifice.

Reports of the Committee on Morbid Growths.

"A microscopic examination of a section made from the growth removed from the uterus, and presented by Dr. Parish, December 28, 1882, shows it to be adenomatous in structure, consisting of small cavities or spaces lined with cells, which cavities are separated from one another by fibrillar connective tissue." "A section of the lymphatic gland presented by Dr. Parish, December 28, 1882, shows that its normal structure is metamorphosed into that of a carcinomatous nature, consisting of an alveolar fibrous stroma having the spaces filled with cells of an epitheliomatous type." "Report on Dr. Eskridge's specimen of brain, lung, liver, spleen, kidney, and bladder troubles, presented November 9, 1882. A section made from one of the nodules of the liver, presented by Dr. Eskridge, examined microscopically, shows it to be a new formation consisting of epithelial cells placed in alveolar spaces; the tissue forming the alveolar walls being fibrillar connective tissue. The cells in the spaces at the periphery of the groups, and lying next to the alveolar walls, have a columnar shape, and are quite regularly arranged, while those of the centre are flat or squamous epithelial cells. The neoplasms are cylindrical-celled epithelioma. The post mortem changes undergone by the brain were such as to prevent any satisfactory histological examination being made.

A Tumor composed of Miliary Tubercles of Subcutaneous Adipose Tissue Connected with one of the Anterior Cutaneous Branches of the Lumbar Nerves.

Exhibited by Dr. Nancrede.

The patient from whom this truly unique tumor was removed was a young girl of 18 years of age, who for four years past had had occasional cough, with at times some bloody expectoration, but was able to attend to her occupation of housework. Her family history was not characteristic in any way. About one year since, she thought that she "strained herself," since when she has been subject to severe attacks of abdominal pain, which extend to various portions of her body. She was admitted to the female medical wards of the Episcopal Hospital last fall, where dullness on percussion and harsh respiration at the apex of one of the lungs was detected. During December, 1882, the pains increased and the right thigh became flexed upon the abdomen. A small, exquisitely sensitive nodulated tumor was now detected just to the outer side of the right rectus abdominis. Dr. Morris J. Lewis, by whose kindness I am en-

abled to present this specimen, then asked me to see the case with him. Under ether I found a nodulated mass, beneath, but attached to the skin, and freely movable upon the deeper parts. I then thought that the growth was one of the ordinary so-called neuromata, *i. e.*, usually fibrous growths in connection with some nerve, and that the pains were reflex, as was also the flexion of the thigh. February 20, 1883, I accordingly removed the growth, which to my surprise was markedly infiltrated, and only at one spot in any sense encapsulated, where it evidently had developed around a small cutaneous nerve and artery. The wound did badly, and has left an indolent ulcer, but *all the reflex pains and flexion of the thigh have disappeared*, while the lung is breaking down; yet the patient is gaining flesh, and looks and expresses herself as much better, and thoroughly satisfied with the results of the operation. I have termed this growth "unique" because I believe that none such have been reported, *i. e.*, subcutaneous masses of tubercle large enough to require the surgeon's knife, and liable to be mistaken for other neoplasms. The present growth was about an inch in its various diameters, as far as could be estimated. Microscopically, sections show fibrous and adenoid tissue, with giant cells according to the kind report of my friend, Prof. Simes, whose observations have been confirmed by Dr. Formad and other pathologists, as well as by myself.

Dr. G. G. Davis said that he had seen a somewhat similar case related in the clinic of Prof. König, of Göttingen. A young man had a subcutaneous tumor just above and to the outer side of the patella. It was about one inch and a quarter in diameter, and perfectly circumscribed. It and a portion of the joint-capsule, including the part to which it was attached, were excised antiseptically. On the synovial membrane were found a number of what appeared to be miliary tubercles. There were no other evidences of tubercular disease, and he recovered with a good movable joint. Prof. König regarded the case as one of true localized tuberculosis. He examined the excised portion microscopically. The tumor was hard, but had undergone cheesy degeneration.

Dr. Nancrede thought that this interesting case, related by Dr. Davis still left his own unique, as Prof. König's case evidently had its origin from the synovial membrane, which was so closely related to the other serous membranes, which, as is well known, are so very prone to miliary tuberculosis.

A section of the growth presented by Dr. Nancrede for Dr. Seltzer, on microscopical examination shows it to consist of an external covering formed of the histological elements and arrangement as found in the skin; the papillæ were in places much atrophied and flattened, also in some parts elongated. There were no hair follicles, sweat or sebaceous glands in the section. Below the papillæ was seen fibrous tissue, at some points in an active state of proliferation, and numerous blood-vessels. The growth is a fibrous polypus.

—Injection of ice-cold water near the trochanter has cured several cases of obstinate sciatica. Ten drops may be used, repeated if necessary.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Action of Rarefied Air.

From the *Med. Press*, February 14, 1883, we learn that Dr. A. Frankel, of Berlin, read recently an interesting paper on the above subject before the Medical Society of that city. For some time past he, in conjunction with Herr Geppert, has been making investigations into the subject, some of the results of which he made public in the paper above mentioned, and of which the following is a very brief account:

Rarefied air is mainly of moment through the diminished supply of oxygen that necessarily accompanies it. The important effects of such a diminished supply have been observed in cases in which the circulation has been greatly disturbed, in hemorrhages, and in the action of most active poisons, as at least the secondary effect of these is to lessen oxidation. It has long been known that when the supply of oxygen to the body is diminished, the organs become subject to a more or less pronounced degree of fatty degeneration. So long as this is limited to the non-use or storing up of such fat as was already in the system, or brought into the system in the food, the process is not difficult of comprehension. The question becomes a different one, however, when, under the influence of a diminished supply of oxygen, fat makes its appearance in localities in which it is not normally present. Such localities are the muscular structure of the heart, the glandular organs in excessive anæmia, in which, under certain circumstances, the muscular structure completely disappears. The author's efforts had been directed to the solution of this problem. He has found that in case of diminished supply of oxygen, brought about, it may be, in the most diverse ways—by suffocation, or by carbonic oxide (CO) poisoning—the urea, or urinary excretion of nitrogen, undergoes a considerable increase. From this it will appear that the diminished supply of oxygen causes an increased disintegration of structural albumen. The nitrogenous components of the albumen are discharged from the system in the urine, and the non-nitrogenous remain in the form of fat. Recent experiments permit this fact to be proved in a manner to which exception cannot be taken. Dogs were enclosed in a ventilated pneumatic chamber, the air of which was rendered gradually rarer by means of an air-pump. After a time, very characteristic phenomena were observed (already described by P. Bert). If the rarefaction was brought about as slowly as possible, when the atmospheric pressure was reduced to one-third, the animals, without any dyspnoea worth naming, fall into a state of somnolence, in which they might remain for some seconds (*Sekundenlang*). In order to ascertain whether this condition, apparently due to the want of oxygen in the brain, might not be really dependent on the mechanical action of the rarefied air on the circulation, the blood pressure was examined. This

showed plainly no deviation from the normal. Neither could there be question of any accumulation of carbonic acid in the blood. It remained, then, that the above-named condition of somnolence was simply the effect of deficiency of oxygen. If the animals, before placing them in the pneumatic chamber, had been fed so carefully that the daily excretion of urea was always the same in amount, it invariably increased considerably on putting them into the chamber and rarefying the air; thus indisputably proving, as Dr. Frankel claims, that the diminished supply of oxygen causes disintegration of structural albumen, with retention of the fatty constituents thereof within the system.

Analyses of Foods.

From the *Chemists' Journal* we take the following:

In a long and interesting article in the *Pharmaceutische Centralhalle* on the nourishing powers of various natural and artificial foods for infants and invalids, Dr. Stutzer, of Bonn, gives the following results as far as concerns their nitrogenous constituents:

FLESH FORMERS.		FLESH FORMERS.	
Per cent.		Per cent.	
Caviar	25.81	Condensed milk . .	.8.79
Revalenta	19.93	White bread	.7.20
Smoked ham	18.92	Biscuit	.6.71
Fresh beef	18.53	Oysters	.5.78
Fowl (breast)	16.56	Cow's milk	.4.00
White of egg	13.48	Extractum carnis . .	3.40
Yolk	13.01	Malt extract	0.28
Infant's food	9.90		

The above table gives rise to some curious reflections. The wonderful nourishing powers attributed to oysters are found to dwindle into insignificance when compared with other food; for instance, a single hen's egg contains as much nourishment, that is to say, as much flesh-forming material, as fourteen oysters, while one-quarter pound of lean rumpsteak is equal to about five dozen of these delicious, but delusive, molluscs.

With regard to condensed milk, it contains much less flesh-forming material than is generally supposed. Taking four per cent for cow's milk as a fair average, the directions on the can, if followed out, give unexpected results. For children's use, we are told to dilute the condensed milk with four or five parts of water. Taking the lowest figure, we should then have five parts of diluted condensed milk, which, according to Dr. Stutzer's figures, would only contain 1.76 per cent of flesh-formers, instead of four per cent, while the milk sugar would be increased from 4.5 to 10.85 per cent. We know that woman's milk contains more sugar than cow's, but still not in the above surprising proportions. Now that so much canned milk is used for infants brought up by hand, it becomes a question how far mothers who cannot suckle their children are responsible

for the health and even lives of their children, by giving them milk from the tin cow instead of that of the living animal.

Dr. Stutzer further exposes the often exposed superstition about the nourishing powers of beef tea. He extracted all the extractible matter from one hundred grams of beef with one hundred grams of water, and a good proportion of salt, at a gentle heat for four hours; but could only succeed in obtaining in solution one-twelfth of the nourishing matter of the beef, the remaining eleven-twelfths remaining behind in the *bouilli*. In other words, we should have to take half a gallon of beef tea made with a pound of beef to each pint of water, before we got as much nourishment as is contained in a quarter of a pound of steak. We might, it is true, evaporate our beef tea down to, say half a pint, but we doubt if it would be palatable to the least squeamish invalid. The high value of eggs, too, is well shown; in fact, roughly speaking, a couple of eggs weighing three and a half ounces are about equal to two pounds of good rump-steak.

Dr. Stutzer, in the course of this article, mentions three samples of cocoa warranted free from fat (*entölter Cacao*) from different houses, which contained respectively 33.48, 32.31, and 30.95 per cent. of fatty matter of some sort.

The highly nourishing powers of caviar will no doubt strike the "general" with amazement.

With the law of libel in its present condition, we have been obliged to omit names, but Dr. Stutzer either has not the fear of the law before his eyes, or they "order these things"—legally, at least—"better in Germany."

A Case of Neglected Presentation of the Shoulder, in which the Prolapsed Arm was Pretended to be Torn Away by the Lying-in Woman Herself.

The following case is taken from the *Edinburgh Medical Journal*, February, 1883:

(*Centralblatt für Gynäkologie*, No. 43, 1882).—This case is recorded by Dr. Wolezynski of Czernewitz. The patient was confined of her third child, her previous two labors having been normal in every way. She at first had no assistance, and as the pains continued upwards of twenty-four hours, and were very severe and almost unbearable, she states that during one of them she pulled upon the arm which had prolapsed, and tore it off. She then sent for an irregular, and finally for a skilled midwife. The latter, on examination, finding the case too difficult for her, advised to call in Dr. Römer. After prolonged and careful examination, Dr. Römer diagnosed a portion of the thorax presenting and wedged tightly into the pelvis. On the right of the swollen presenting thorax he reached a part where shreds of skin and muscle with portions of ribs could be felt, but no arm. He could also reach by the examining finger close to the neck, but could not get high enough up to decapitate. After closely examining the case he got the parturient woman to confess that the arm had been torn off. He now sent for Dr. Wolezynski to aid him in the management of the case. They agreed that evisceration was the best method to adopt in the circumstances, and succeeded in delivering in that way. The uterus was so tetanically contracted that

they dared not think of turning. It ought to be noted that the labor began on Saturday, and it was not till Monday morning at 8 o'clock that Dr. Römer was called in. The child was a well-developed boy. The right upper extremity was completely wanting, the glenoid cavity of the scapula was laid bare, the skin on the breast and dorsal muscles was retracted, etc. The discharge was very fetid. Notwithstanding this and the fact that the author omitted washing out the interior of the uterus with carbolic solution on purpose, the patient made a good recovery. Dr. Wolezynski's reason for not washing out the interior of the uterus in such cases is somewhat peculiar, viz., that when the room, linen, and entire surroundings of the parturient woman are filthy, in spite of every effort in the direction of cleansing instruments, infection by air is probable. He advised the woman, however, in this case to wash out the *vagina* with a two per cent. solution of carbolic acid. The author comes to the conclusion that it was simply impossible for the lying-in woman to have torn off the arm of her child as she said, as she would have not only required to have pulled upon the prolapsed arm, but to have grasped it above the elbow and dragged it backwards, as there was no sign of injury to the anterior part of the vulva. He believes that the irregular midwife who was first called in had torn off the arm, and that the patient had incriminated herself to screen the other.

Abscess Discharging at the Umbilicus in an Infant.

In the *Boston Med and Surg. Jour.*, February 1, 1883, Dr. C. W. Stickney reports the following case:

When first called to the case, in April last, I found the child suffering evidently from gastrointestinal derangement, manifested by vomiting of everything taken into the stomach, slight febrile disturbance, thirst, sleeplessness, and constipation. There was some tympanites, but at first no tenderness of the abdomen. The tongue was covered for the most part with a thick, soft, white fur. The child had been troubled more or less with constipation from birth, otherwise had been healthy. Suspecting intestinal obstruction, I administered castor oil, which, however, affected the bowels naturally, thus relieving anxiety in this direction. After two or three days I found on palpation a circular area of induration about three inches in diameter, having the umbilicus as its centre. The umbilicus seemed to rest in a cup-shaped depression in the surface of the tumor; the swelling and induration were accurately defined by an abrupt though somewhat rounded circumference. Very light percussion revealed dullness over the affected region; deep percussion was tympanitic, like the rest of the abdomen. Hop-bags and cloths wrung out of hot water were applied to relieve discomfort. Soon, however, the umbilicus began to push forward as a rounded red tumor, which soon showed distinct fluctuation. Suppuration being now certain, light poultices were applied, and on the sixth day the umbilical tumor ruptured, and discharged a small quantity of healthy pus. Some relief of symptoms followed, but the circular tumor remained in the same condition. Poultices were

continued in the hope of keeping up the discharge, so that eventually the abscess might thoroughly evacuate itself through the external opening, thus lessening the risk of rupture into the peritoneal cavity. Matters now progressed well; there was a constant, free discharge of pus, and the indurated mass was perceptibly softening. But on the morning of the ninth day, while straining to evacuate the bowels, the patient passed suddenly into a state of collapse, and never rallied. An autopsy was not permitted.

When asked for a diagnosis, I gave: Either abscess of the abdominal wall external to the peritoneum, or localized suppurative peritonitis circumscribed by adhesions—death in either case being caused by rupture into the peritoneal cavity.

Pelvic Peritonitis.

Dr. Andrew Semple reports the following case in the *Glasgow Med. Jour.*, February, 1883:

A. F., æt. 22, weaver, admitted 27th December, 1882.

On the 17th of November last, patient gave birth to a living female child; she made an excellent recovery, and in four weeks returned to her work, but after a week she was obliged to confine herself to the house on account of a pain which started in the left iliac region, and gradually extended across the hypogastric to the right iliac region; accompanying the pain were considerable thirst, anorexia, diarrhoea (attributed by patient to a mixture got from a doctor), nausea and vomiting, suppression of milk, and the formation of an abscess in the left breast, which subsequently burst and then healed up.

On admission, these symptoms were still present, with the exception that constipation had taken the place of diarrhoea. Pulse 108, small and wiry; respirations, 28; temperature, morning 100.2°, evening 103.2°; face flushed; tongue furred. The pain in the hypogastrium was relieved somewhat when the thighs were flexed on the abdomen, and aggravated by pressure, even of the bed-clothes. On palpation, in the hypogastric and iliac regions, numerous irregular indurations could be felt all over.

On 29th December twenty-four half-grain powders of *hydrarg. ē creta* were ordered, one every two hours during the day, and every four hours at night. In five or six days afterwards the indurated masses were found to have softened considerably, on the 10th January the powders were repeated as before, and on the 15th the indurations had entirely disappeared, and the patient was perfectly convalescent.

I beg to call the attention of medical men to the method of treatment (detailed above) of an affection whose stubborn resistance to the action of almost any remedial measures has already become proverbial. The exudation into the broad ligaments, etc., was of the usual fibrinous character, and gave the impression to the hand of almost stony hardness. I have found that gray-powder in such minute doses is besides a powerful stimulant to the action of the kidneys, even during the nephritis following scarlatina, and, what is somewhat extraordinary, its use in such doses is not contra-indicated in the albuminuria which attends such cases.

Peripheral Vascular Tone.

The *Edinburgh Med. Jour.*, February, 1883, says: It has been debated whether the vascular wall contains in itself the cause of its own rhythmic contractions, or whether the latter are to be regarded as dependent on a central innervation. Experiment has hitherto pointed to the latter hypothesis as the correct one; but more recently, Luchsinger, after considerable research on the bat's wing, has come to a different conclusion. The veins in the wing of a narcotized bat continued to pulsate powerfully after all the structures (except the afferent and efferent blood-vessels) connecting the wing with the animal's body, had had been divided. Any sympathetic nerve twigs running along the vessels were destroyed by painting the surface with strong ammonia. Further, when, ten minutes after death, defibrinated filtered ox-blood, of the temperature of the room, was passed through a canula into the aorta of an asphyxiated bat from a height of 40–50 cm., the veins filled out and commenced to pulsate, and continued to do so for twenty hours. Luchsinger considers that variations in pressure determine the contractions. If the pressure was zero, the pulsations ceased, although blood or salt solution was still flowing; but if the pressure was raised to 40–50 cm. (water), the veins soon commenced to expand, and the rhythmic play of the vascular wall to show itself. The contraction is due to the irritation caused by the dilatation of the contractile wall. Schiff, also, has recently made similar though independent experiments, and his results correspond with those of Luchsinger (B. Luchsinger, *Pflüger's Archiv.*, 1881, B. 26).—Auerbach, in *Centralb. f. Chirurg.*

The Effect of Salicylic Acid.

The *Am. Pract.* has the following translation from *Berlin klin. Woch.*:

Its ordinary effects are, difficulty in hearing, ringing in the ears, headache, vertigo, drowsiness, and delirium. During fever the temperature is considerably lowered; after a large dose, sometimes profuse sweats occur, then urticaria and erythema, nausea, vomiting, diarrhoea, seldom albuminuria [blood from the kidneys.—*Translator*]. A few authors mention difficulty in breathing, either a simple dyspnea or hard inspiration, with or without slowness of the same. Dr. Quinke believes the impaired respiration the most common phenomenon of salicylic acid. Its continued use is always accompanied with very hard, but not slow breathing; the frequency never changed in his experiments; also the pulse was not changed. The doses causing such effects were different. Dr. Quinke reports a case having these symptoms, the patient dying from hyperemia of the brain due to the drug, although the dose had been only an ordinary one. The impaired respiration here is similar to that of diabetes, and judging that a certain substance (acetic ether) produced by diabetes be the cause of that phenomenon, and on the other hand that only a small quantity of the salicylic acid could be detected in the organs after death, Dr. Q. believes that a similar substance, and not the drug directly, might produce the impairment of respiration.

THE
Medical and Surgical Reporter,
 A WEEKLY JOURNAL,
 ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
 JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
 115 South Seventh Street,
 PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
 OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

SYPHILIS AND RACHITISM.

At a recent séance of the *Soc. de Chirurgie*, M. Parrot, at the request of M. Verneuil, laid before the society the results of his researches on the near connection binding together these two morbid conditions. Rachitism is the product of syphilis; but syphilis, before arriving at the period when the lesions of rachitism are found, has passed through many intermediary stages, or phases of transition. To determine the syphilitic origin of rachitic lesions is a very difficult matter; it is very rarely that any information can be demanded on so delicate a subject from the parents, and the criterion of diagnosis must be sought for in the traces of syphilitic disease found in the children themselves.

These signs may be ranged under several categories. First come the syphilides found on the skin of the buttocks, thighs, etc. Secondly, various lesions of the viscera are found at the autopsy. A third means of diagnosis, according to M. Parrot, exists in a species of desquamative syphilide of the tongue. Finally syphilis has a special action on the teeth in these children, inducing special lesions of the teeth during both primary and second dentition.

The varieties of these alterations are numerous, the capsular alteration (alteration en capsule) found on the anterior and posterior surface of the incisors; the transversal grooving and the cuspidian alteration of the molars; in another form the teeth are eroded at their bases. All these lesions are systematic, and are found in the same order; they may persist during the entire period of life, and are under the dependence of inherited syphilis.

Passing to a complete and thorough examination of the visceral lesions and those affecting the bones, M. Parrot gives a description of the bone lesions, which are always identical, polymorphous, and finally constitute the rachitic condition.

They may be found during the last months of the intra-uterine period, and up to the period of second dentition. Three principal types are observed:

The first is constituted by osteophytes; the

bones are deformed, and the extremities and diaphysis, though intact, are surrounded by hard and friable masses. The tibia and humerus are principally affected.

The second condition is constituted by a species of gelatiniform atrophy. The diaphysis is often found fractured, and there frequently exists what M. Parrot terms a "syphilitic pseudo-paralysis."

The third type is characterized by the appearance of spongoid tissue, or classic rachitism, the extremities of the long bones are affected, and bending and fractures of the bones are found.

These syphilitic lesions have a very near connection with those found daily at the autopsy of rachitic subjects, and it is impossible, in the presence of such evidence, not to conclude that the causes which induced the first alterations also produced those found in the last period. Authors who have studied rachitis have invoked the most diverse causes to explain its origin.

But these causes, alcoholism of parents, premature or imperfect nursing at breast, enteritis, bad hygienic conditions, etc., are not sufficient of themselves to produce rickets. The presence of a morbid germ, a constitutional defect, which finds in these special causes and the state of debility they induce a soil proper for its development, is necessary for the proper evolution of the rachitic disease. This germ, this constitutional defect, is congenital or hereditary syphilis.

PHYSICIANS' PRESCRIPTIONS IN THE OLD WORLD.

There has been so much said on the continent about the sale of medical diplomas in the United States, that it has been supposed there generally that American physicians were very ready to resort to any means to increase their profits. The physician is very often suspected of being in collusion with the druggist and of receiving a certain percentage, but it appears that we are yet as infants in this respect, compared with some of our continental confrères.

According to the feuilleton of one of the recent issues of the *Gazette Hebdomadaire*, some of the very respectable physicians of Paris, not satisfied

with prescribing as large a quantity of a medicament as frail human nature is capable of bearing, are careful to place at the head of the prescription, "treatment for two, three, or four months," as the case may be. The patient will be informed at the druggist's that a certain time will be required to fill out the prescription, and that it will be sent to his residence.

The medicaments are received the next day in bottles, in boxes, in baskets; a large quantity, you will say, but, my dear friend, it comprises a four months' course of treatment, and if you are unable to continue it beyond the third day, it is not, most certainly, the fault of our genial friend the doctor, or his very efficient aid, the apothecary.

What can be said of a prescription of this kind ordered by a physician occupying a high official position in Paris in which a "hematogenous wine," figures up to 180 francs; a "ferruginous essence," 80 francs; a "mineral salt," 125 francs; a skin application, 60 francs; arsenical pills, 60 francs; the grand total for the prescription reaching the respectable sum of 700 francs, or 140 dollars.

EVOLUTION.

The doctrine of transformation, man descended from the monkey, the monkey from some inferior animal, and this last from some animal still lower in the scale of beings, descending thus to the original polyp, has been considered exclusively a modern doctrine, perhaps thought of originally by Diderot, but of course principally credited to Darwin.

However, there is nothing new under the sun, and M. Halevy, of the Académie des Inscriptions et Belles-lettres, has found among the works of an individual named Sanconiathon, who lived, according to the savants, precisely between the fourth and twentieth centuries, B. C., the following passage, which was reproduced from the original work by Philon of Byblos, and later by Eusebius: "(Then) there was [on the earth] living beings deprived of intelligence, from whom descended beings gifted with intelligence, who were called Zophasamin, contemplators of heaven."

SANITARY LEGISLATION.

For a wonder, a jobbing bill has been defeated before Councils.

For some time past, a number of prominent physicians have been actively engaged in securing legislation to regulate the plumbing and draining of dwellings.

After preparing a good bill, and resting content that it had been put in the proper channel to reach Councils, they waited; when, to their astonishment, they discovered that a *jobbing* bill had been prepared and presented to the Committee in its place. In many particulars the bills are identical, but in the essential point (the appointing power) which would make the legislation valuable or otherwise, they diverge widely, as the following comparison will show:

JOBGING BILL.

"The Chief Engineer and Surveyor of the City" (a politician) "shall appoint eight inspectors, whose duty, under and subject to his direction, shall be to examine all plumbing and house drainage work, and if the same be in accordance," etc. etc.

PHYSICIANS' BILL.

"Eight District Inspectors shall be appointed by a committee composed as follows: Three physicians, appointed by the County Medical Society; three architects, appointed by the Philadelphia Chapter of the American Institute of Architects; three plumbers, appointed by the Master Plumbers' Association; and three citizens, appointed by the Board of Health."

Comment is unnecessary—the *good* bill is obvious. Suffice it to say that the *jobbing* bill has been defeated, and that when Councils reconvene, the better element will be so strong, that we can reasonably hope for a speedy passage of the worthy ordinance.

NIEMEYER ON THE DEATH OF GAMBETTA.

It is announced that Prof. Niemeyer, in a lecture on the malady and death of Gambetta, affirmed that the illustrious patriot was, like Garfield, the victim of his physicians, and died, not of his wound, but from the effects of the treatment.

The patient, he affirms, had superabundant flesh, and was of a very sanguine temperament, in other words hot-blooded. He was allowed to eat and drink too much, was confined to his room, and deprived of water and air. A more frugal regimen, lighter food, plenty of air, and frequent baths, would have saved Gambetta.

Niemeyer made these assertions and strictures before the medical report appeared, simply from the statements made in the daily journals. It is simply another example of the discourtesy shown by the German physicians towards Garfield's surgeons, and towards Pasteur and his discoveries.

NOTES AND COMMENTS.

The Salicylates and Hæmorrhages in Enteric Fever.

Dr. James Fergusson writes as follows in the *British Medical Journal*, February 17, 1883:

At a time when salicylic acid and its compounds are receiving so much attention, may the following facts be regarded as at least worthy of statement? Last year, while resident in the infirmary here, I had an opportunity of testing the efficacy of certain drugs as anti-pyretics in enteric fever. These agents were used successively, each over a group of cases, and included the salicylate of soda. The latter had not been long in use when an increased frequency of hæmorrhages from the bowel raised the question, "Could the salicylate be favoring the production of that complication of the malady?" Whether it were or not, the suspicion aroused dictated the withdrawal of the salt from use in cases of typhoid. Shortly afterwards, I noticed that a foreign observer had reported the salicylate of bismuth, and, I think, also, salicylic acid (though of the latter I cannot be certain, as I am not able now to find the report in question), to cause intestinal and nasal hæmorrhages. The subject would not have been revived by me at present, but for the recent experience of my successor in the resident's office of the above-mentioned institution, Dr. H. McLean Wilson, who joins me in placing the facts before the readers of this journal. Dr. Wilson, in having recourse to the soda-salt in typhoid, found the same striking frequency of hæmorrhages to follow closely. His employment of the agent differed from mine, in that he administered small doses of ten to fifteen grains frequently over the twenty-four hours, while I gave half drachm or drachm doses at longer intervals apart. In the other respect, however, our experiences have been so similar as to warrant the facts being brought under notice, so that the important practical question involved may, if possible, be decided by the evidence of a number of observers. I hope you may favor such an inquiry.

Instructions to German Midwives.

The following is from the *Medical Press and Circular*:

1. Medical science has, for a number of years past, arrived at the fixed conviction that the great majority of cases of childbed fever depend for their origin upon the inoculation of recent wounds (produced more or less in every case of labor) by putrid (so-called septic) poisons.

2. These poisons readily cling—but in an im-preceptible manner—to every kind of utensil that may come into contact with the woman in labor, unless they are kept scrupulously clean.

3. But it is the hands and instruments of the obstetrician that have become known to be especially dangerous bearers and disseminators of the poisons, as it is impossible to avoid bringing these into contact with dangerous putrefying material.

4. Simple, and even repeated, washings with soap and water, as observation has shown, will not remove the poisons that may be clinging to the hands and instruments. The slightest trace of such poison will, however, suffice to set up the gravest—yea, even fatal—childbed fever.

5. Wherefore it is the most sacred duty of every midwife, as of every physician, *in other ways* so thoroughly to cleanse the hands and instruments, and whatever other appliances may be brought into contact with the patient, that she may not be inoculated by any poisonous matter.

6. We are able, as we learn by observation, to destroy the poison, or, at least, render it powerless, by boiling water, and especially by the stronger solutions of carbolic acid (two to five per cent.).

7. The simple rinsing of the hands in carbolized solutions that are too weak, can afford no protection against childbed fever.

The Treatment of Hepatic Diseases.

Dr. J. Kingston Fowler (*Lancet*, January 20, 1883,) considers that the trocar is preferable to incision for evacuating hepatic abscesses, for the following reasons:

1. The risk from hemorrhage is much less; for when the liver is incised there is often a violent gush of blood. This, it is true, soon ceases; but these patients are usually not in a condition to bear a loss of blood which a distinguished surgeon, Mr. Lister, describes as “alarming.”

2. There is less danger from septic absorption along the track of the wound, as the pus flows through a canula or drainage tube.

3. As a trocar of any diameter may be used,

the opening into the sac may be of any size that is considered desirable. For an exploratory puncture I prefer one having a diameter of one-eighth of an inch; but if there is certain evidence of the presence of pus, it is very important to employ an instrument of at least three-eighths of an inch or half an inch in diameter. If a smaller one be used, it is liable to get blocked by the solid shreds of liver tissue which these abscesses so frequently contain.

The Origin of Respiratory Murmurs.

Chomiakoff and Kotovshtchikoff having repeated the experiments of Aufrecht and Halbertsma, and completed a series of experimental researches of their own (*Dnevnik Kazan. Obst. Vrachei*, Nos. 13 and 14, 1881), sum up their results as follows:

1. Aufrecht's theory is incorrect; that is, the bronchial respiratory murmur does not in the least depend upon the movements of quiescent air-columns within the lung.

2. The bronchial murmur originates exclusively in the larynx; the friction of the air against the walls of the large bronchi does not give rise to these sounds.

3. The vesicular respiratory murmurs are of a compound nature. A large part of them have a laryngeal origin; that is, the bronchial murmur originated in the larynx, while passing through the normal tissues of the lungs, changes its characters, and is heard on the lung-surface as a vesicular murmur. The remaining part of the vesicular sounds originates on the periphery of the lung, but the authors are not as yet able to elucidate its mechanism.

Double Ovarian Dermoid Cysts.

At a recent meeting of the Academy of Medicine in Ireland (*Dublin Jour. Med. Sci.*, February, 1883), Dr. Poole showed, for Dr. Kidd, two dermoid ovarian cysts removed from an unmarried patient, aged thirty-eight. Growth of tumor noticed for three years. The larger tumor involved the left ovary, and weighed on removal about six pounds. It is composed of numerous loculi of various sizes, some containing glairy mucoid fluid, and others masses of sebaceous matter mixed with hairs. Hard centres of ossification were felt in portion of cyst walls; one of the larger cysts contained a matted mass of long dark hairs, on removing which a mass of bone was found jutting sharply into the cavity, and bearing on its apex two closely-united teeth. The smaller tumor belonged to the right ovary, and is seen to consist of

two cavities, one containing sebaceous matter with a few hairs, and in one part of its walls a mass of bone; the other containing a quantity of light-colored hair, and several teeth irregularly set in a bony wall.

An Account of Two Hundred and Eight Consecutive Cases of Abdominal Section Performed between March 1, and December 31, 1881.

The *Brit. Med. Jour.*, says that Mr. Lawson Tait, F. R. C. S., Eng., Surgeon to the Birmingham and Midland Hospital for Women, in a paper bearing this title, gives the following analysis of the series: Exploratory Incisions, 13 cases, with no deaths; Incomplete Operations, 8 cases, with four deaths. Operations for Cystoma: One Ovary, 36 cases; Both Ovaries, 28; Parovarian Cysts, 12; Hydrosalpinx, 16; Pyosalpinx, 20; or 112 cases, 3 deaths. Removal of Uterine Appendages: for myoma, 26 cases; for Chronic Ovaritis, 12; for Menstrual Epilepsy, 1; or 39 cases, 5 deaths. Hepatotomy for Hydatids, 2 cases; Hydatids of Peritoneum, 2; Cholecystotomy, for Gallstone, 2; Radical of Hernia, 1; Nephrotomy for Hydatids, 1; Nephrectomy, 1; Intestinal Obstruction, 1; Solid Tumors of Ovary, 3; Hysterectomy for Myoma, 10; Cysts of unknown origin, 1; Tumors of Omentum, 1; Pelvic Abscess opened and drained, 7; Chronic Peritonitis, 4; or 35 cases, 4 deaths. Total, 208 cases, with 16 deaths. These operations were not performed under carbolic spray.

Sustained Muscular Effort.

A remarkable instance of sustained muscular effort is given in the *Medical Press* as having occurred in an Australian mine. The drift from one shaft having unexpectedly broken into another, a rapid inundation took place, so that in a few minutes the lower levels were flooded, and the water stood thirty feet in the shaft. Twenty-seven men in one part of the workings were unable to ascend the shaft, being caught in a drift where the water soon rose so high that only by clinging to the timbers could they keep their chins above it. One by one during the terrible sixty hours that elapsed before help came did the men drop off exhausted; but five of them succeeded in holding on during the whole of that time and were brought out alive. The bodies of the other twenty-two were found scattered about on the floor of the drift. Great indeed are the strength and tenacity inspired by desperation, when they could enable five men to hang on by their hands with their bodies immersed in water for sixty hours.

Orchitis in Typhoid Fever.

In the *Lancet*, December, 1882, p. 994, an article appears noting the rarity of this complication in the older text-books. The orchitis comes on suddenly, does not involve the epididymis, and generally appears at the end of the pyrexial stage or some days after. It is seldom severe, and is never of a neuralgic character; the inflammation is always unilateral, and is more common on the left than on the right side. As a rule, the congestion ends in six to ten days; but sometimes it may go on to suppuration and complete destruction of the organ. Dr. Hamilton (at p. 1039) gives the notes of a case in which an attack of acute pain and swelling of the right testicle came on some days after convalescence commenced. In a short note at p. 1065, Mr. Manly gives his personal experience of an attack of orchitis with (?) phlebitis of both external saphenous veins, which came on during convalescence from a mild attack of typhoid fever.

Compound Fracture of the Femur, with Complications—Recovery.

Dr. Arthur E. Baker describes a case in the *Brit. Med. Jour.* at great length; the patient was a rivetter, aged 29, who fell from a roof and fractured his femur. The case illustrates, in the first place, what is, however, unfortunately rare in experience, namely, the possibility of recovery from pyæmia, even in a patient weakened by a most severe injury, prolonged suppuration, and an attack of erysipelas. Secondly, it illustrates the feasibility in some cases of amputating with the best results through the thigh for compound fracture, leaving a second compound fracture in the neighborhood of the hip-joint to be treated otherwise later on, when the first amputation wound is healed. Thirdly, it shows that, in such a case, it is possible to exarticulate the whole of the remaining bone up to the hip-joint, without re-amputation through the soft parts, but through a moderate opening in the outer side of the stump.

Iodine Blisters in Tabes Mesenterica.

The *Med. Press*, February 14, 1883, says:

In tabes mesenterica, Dr. Bouchut, of the Children's Hospital, recommends the application of blisters, or the tincture of iodine, upon the abdomen, and if ascites were present, tapping should be employed without hesitation. The régime to be followed should be very severe—beef-tea, eggs, raw milk, and claret. If diarrhœa be present, enemata of borax, one drachm each time, should be given, and three or four teaspoonfuls of

glycerine in the day, by the mouth. Bismuth, or phosphate of lime, would be very useful. Your correspondent tried this treatment in an apparently hopeless case, and a rapid recovery ensued. The disease was far advanced, and the child was abandoned by its ordinary medical attendant.

Fatal Tetanus Complicating Typhoid Fever.

Dr. Simoneau relates the following: A man, aged sixty-six, was attacked with typhoid fever of rather severe form, and a little irregular in its symptoms. The fever had begun to abate, and the patient was supposed to be entering upon convalescence, when he was suddenly seized with vomiting and pain in the epigastrium. On palpation, a rigidity of the muscles of the right side of the abdomen was noticed. A few days later the muscles of mastication became affected, and the patient developed all the symptoms of tetanus, and died in thirty-six hours. The hygienic surroundings of the patient were of the best, and no cause for the tetanus could be discovered. Dr. Simoneau could find no similar case reported of tetanus complicating typhoid fever.

Hydrotherapy in the Treatment of Syphilis.

The *Med. Record*, February 10, 1883, quoting from the *Jour. de Med. de Paris*, No. 15, 1882, says that Dr. Pascal advocates the employment of cold water, conjoined with the internal administration of specific remedies, in the treatment of syphilis. He states that it is of great service in its early stages, by virtue of its tonic effects, in overcoming syphilitic anæmia. In the later stages, it is employed with advantage in the various cerebral accidents of specific origin. He condemns the thermal baths, however, as tending to cause the very cerebral complications for which the cure is sought. The cold bath alone is of little utility, but should always be regarded as an adjuvant to internal medication.

Chancre on the Chin.

In the *Jour. Cut. and Ven. Dis.*, February, 1883, Dr. Morrow relates the case of a man in whom there was an indurated crateriform typical chancre on the front of the chin, just below the free border of the lips, which had been there for three weeks. The patient ascribed it to a cut from a razor in a barber shop. He has now a general roseola (the chancre having healed), and on the dorsum of the penis, about one inch above the corona glandis, is a small circular non-indurated erosion, with a reddish-white base, covered

with small granulations secreting a small quantity of thin fluid. This has been there three weeks.

Pruritus Vulvæ.

M. Vigier, in the *Gaz. Hebdomadaire*, January 26, gives the following preparations as the best in the treatment of this distressing affection:

1. *Gowland's Lotion*, which contains 15 centigrammes of sublimate to 100 grammes of milk of bitter almonds.

2. *Vidal's Lotion*: this contains 3 or 4 grammes of chloral hydrate to 100 grammes of rose-water. After each application the part to be dusted with starch-powder.

3. *Guéneau de Mussy's Pomade*: Glycéré of starch 20 grammes, subnitrate of bismuth and bromide of potassium aa 1 gramme, calomel 20 centigrammes, and extract of belladonna 25 centigrammes. To be applied every evening to the pruriginous region.

Dangerous Hemorrhage from External Genitals During Labor.

Dr. Peter Young calls attention, in the *Med. Press*, February 14, 1883, to a case in which there was persistent bleeding after the delivery of both child and placenta. Notwithstanding the vigorous application of the usual restoratives, the woman died in a few minutes, and before arrangements could be made to perform transfusion.

On post-mortem examination the source of bleeding was found to be a tear at the upper margin of the vulvar orifice, extending from the left side of the urethra up towards the clitoris. Numerous venous sinuses and two or three small arteries were lacerated.

The Value of the Carbolic Spray.

At a late meeting of the Medico-Chirurgical Society of Edinburgh (*Lancet*), Dr. John Duncan communicated the result of the very important series of experiments which he has been carrying on for the past year, and which seem clearly to show that the carbolic spray is useless as a means of preventing putrefaction in wounds. It is Dr. Duncan's intention to publish his results shortly.

Body Temperature in Different Situations.

Dr. Henry L. Taylor (*New York Med. Record*, Nov. 18, 1882), has found that the difference between the axillary and rectal or vaginal temperature in typhoid fever, while usually about a degree higher in the latter situation, may vary as much as 2° F. sometimes in favor of the axilla, sometimes of the rectum or vagina.

SPECIAL REPORT.

NO. XII.—OPHTHALMOLOGY.

BY CHAS. S. TURNBULL, M. D.

The Following, from the Progress of Ophthalmology During the First Quarter of the Year 1882, by H. Magnus, Breslau; C. Horstmann, Berlin; A.

Neiden, Bochum, and others, are of Particular Interest.—Archiv. of Ophthalm., vol. xi., No. 3.

(Continued from page 361.)

Teillais. *Tumors of the Orbital Region.* Ann. d'Ocul., January–February, 1882, p. 44. In a man of 32 a cyst developed from the frontal sinus, which dislocated the left eye downward. After its removal, the eye again resumed its normal position; nothing remained but a scar in the supra-orbital region. In a young man of 19 an ivory tumor sprang from the frontal sinus, which dislocated the eye downward. As the tumor had a broad base, it could only be partially removed.

Dor. *Congenital cyst of the orbit.* Microphthalmus, Colobome de l'Iris et de la Choroïde. Rev. Génér. d'Ophthalm., 1882, No. 2, p. 81. Dor describes a congenital cyst of the orbit, which was complicated with microphthalmus; the eye had a coloboma of the iris and choroid.

Eales. *Birmingham Med. Rev.*, January 4, 1882, p. 46. *Pulsating exophthalmus*, with paralysis of 3d, 4th, 5th, 6th, and 7th nerves, and blindness from absolute glaucoma, following severe crush of the head. Probably fracture of petrous bone and rupture of internal carotid. (E. Mettleship.)

Lewkowitch. *Two cases of interstitial keratitis.* Zehender's Monatsbl., vol. xx., p. 12. In a case of gastritis, Lewkowitch observed the occurrence of interstitial keratitis, which grew better or worse according to the state of the former. Iodide of potash cured the whole affection. In another case, interstitial keratitis set in. Here a quotidian intermittent fever was followed by a chronic gastric catarrh.

Pflüger. *Specific parenchymatous keratitis.* Ophthalmic Clinic of Berne University. Rep. for 1880, Berne, 1882, p. 31. As soon as the most severe symptoms of irritation have disappeared, the author advises in specific parenchymatous keratitis the use of a vaseline salve (5%) of the yellow oxide of mercury, gradually increasing its strength to 3%.

Colsmann. *Case of recurrent affection of the cornea in gonorrhœic arthritis.* Berl. Klin. Wochenschr., No. 16. Colsmann observed in a gentleman who was troubled several times with affec-

tions of the joints after gonorrhœa, the appearance of recurrent keratitis.

Cheatham, W. *Inoculation for pannus*, with a case. Amer. Practitioner, February, 1882. The inoculation was made of pure gonorrhœal matter. Before treatment there was but little more than perception of light; after the inflammation had subsided $V=\frac{10}{205}$. (Burnett.)

Pflüger. *Traumatic herpes of the cornea.* Conf. f. c., p. 28. What Pflüger understands by traumatic herpes of the cornea is an eruption of vesicles upon the cornea of elderly people. It has the appearance of ordinary herpes vesicles. All the patients had previously been operated upon. Pflüger, therefore, thinks that the irritation due to the operation is a factor contributing to the development of the disease. The affection lasts from four to fourteen days.

Kroll. *Contributions to the knowledge of neuro-paralytic keratitis.* Centralbl. f. prakt. Augenhelk., 1882, p. 72. Kroll observed in a woman left-sided herpes zoster, conjunctivitis, and opacity of the cornea. The perception of heat and cold was preserved in the affected parts, but perception of pressure and pain lost. There were also paresis of the abducens and considerable dilatation of the pupil. An ulcer developed upon the cornea, making necrosis probable. Iodoform dusted into the eye, combined with a bandage, gradually brought about recovery.

Böckmann, E. *The nature and causes of the corneal affection accompanying anæsthesia of the trigeminus.* Bergen, 1882, 163 pages. The author subdivides his treatise into two sections, an experimental and a clinical one. After viewing the most important contributions of others on this subject, he reports the results which he arrived at after about 100 experiments upon cats.

In all essential points they agree with the investigations of Feuer, according to whom the corneal affection developing after intracranial division of the trigeminus must be explained as a xerosis of the cornea and a xerotic keratitis resulting from it. The author lays especial stress upon the importance of repeated and accurate tests of the sensibility of the eye and its adnexa, as in this way only it can be ascertained whether or not the trigeminus has been completely divided. In the clinical part Böckmann describes a xerosis of the cornea and xerotic keratitis which frequently occur among lepers. As these processes, according to the author, are synonymous with so-called neuro-paralytic keratitis, he believes, in opposition to Bull and Hansen, that the latter disease is not rare among lepers. (Bull.)

Blanch. "*Rheumatic periscleritis.*" *Reed. Opth.*, 1882, Nos. 2 and 3. Blanch reports a case of rheumatic periscleritis. It was cured in 6 days by alternate instillations of atropine and eserine, and internal treatment with quinine. (Markwort.)

H. R. *Massage oculaire.* *Annal. de la Soc. Med. Chir. de Liege*, March, 1882. The author discusses massage of the eye according to Pagenstecher's method, and recommends this method of the treatment especially to mild cases of phlyctenular conjunctivitis, and in subconjunctival hemorrhage, which disappears more rapidly when thus treated; it is also useful in hypopyon and hyphæma.

Coomes, Martin F. *Osseous degeneration of the eye.* *Med. Herald*, March, 1882. The degeneration was the result of an inflammation of the uveal tract, occurring during childhood. The hyaloid and choroid were transformed into a bony shell, with an opening corresponding to the optic nerve entrance, with a diameter of one-twentieth of an inch. The anterior portion had points of chalk deposit. (Burnett.)

Goldzieher. *On disseminated choroiditis.* *Wien. Med. Bl.*, No. 10, p. 302, and *Pesth. Med. Chir. Presse.* Meeting of March 4. The author thinks that the genetic and anatomical relation between disseminated choroiditis and retinitis pigmentosa is closer than has heretofore been supposed to be the case, the latter affection being nothing else than a form of chronic plastic choroiditis. The pigment in retinitis pigmentosa originates in the choroid.

V. Hasner. *Case of primary sarcoma of the iris.* *Prag. Med. Wochenschr.*, No. 6, p. 58, 1882. The left eye, which was the affected one, had been injured 15 years ago, and after that slightly several times. The tumor had slowly developed in the upper-outer-quadrant of the iris; its base extended from the periphery of the iris to the edge of the pupil. $V=\frac{1}{2}$. This reduction of the power of vision was probably due to secondary hyperæmia of the choroid and retina. Among 32 cases of sarcoma of the uveal tract, 2 cases only were confined to the iris.

Kipp, J. C. *Two cases of sarcoma of the choroid*, presenting unusual clinical features. *Trans. Amer. Opth. Soc.*, 1881. In both cases the tumor had grown to a considerable size without producing an increase of tension or total detachment of the retina. With the exception of these symptoms, both cases agree with the description of detachment of choroid given in the text-books.

Agnew, C. R., and Webster, D. Report of some cases of *glaucoma in which an iridectomy on one eye*

seemed to precipitate an attack of acute glaucoma of the other. *Med. News*, vol. xi., No. 8, February 25, No. 476.

Heyl, Albert G. *Acute glaucoma caused by duboisia.* *Amer. Journ. Med. Sci.*, April, 1882. The patient, a woman of 55 years, was already suffering from a simple glaucoma. A two-fifths per cent. solution of duboisia was instilled for dilatation of the pupil for ophthalmoscopic examination. Sub-acute inflammatory glaucoma developed in the course of a few hours, for which an iridectomy was done with a happy result.

Mauthner. *The excavations of the optic nerve.* *Wien. Med. Bl.*, No. 10, p. 300. In this paper the author declares in favor of the theory that glaucoma is a form of serous choroiditis. It is this, and not the increased intra-ocular pressure, which destroys sight, those cases being known to be the worst in which $T=n$. Choroiditis is the primary affection, the increased pressure only a secondary symptom.

Rheindorf. *Case of glaucoma with acute opacity of the lens.* *Zeh. Klin. Monatsbl.*, vol. xx., 1882, p. 15. In a man with incipient senile cataract, acute glaucoma of the left eye developed, which was followed at once by opacity of the lens. The author endeavors to assign the same cause to both affections. The more the zonula is stretched by the increased intra-ocular tension, the less permeable it becomes. Thus the nutrition of the lens suffers, the consequence of which must be the rapid development of cataract.

Wagner. *Statistics of glaucoma* (Min. of the meetings of the Med. Soc. of Odessa, 1881, No. 17) confirms the observations of Benedict, Rosa, Arlt, Ridel-Schmidt, and Kranhals, of the more frequent occurrence of glaucoma among the Jews, and seeks to explain it as a hereditary peculiarity of the race.

Critchett. *Practical remarks on cataract.* *Ophth. Rev.*, vol. 1, No. 4, Feb., 1882, p. 73, continued from p. 26. As regards an operation, the author advises not to operate upon the one until there is a marked diminution of sight in the other. But if symptoms of general constitutional degeneration are observed, it is advisable not to postpone the operation if the cataract is ripe, even though sight in the other eye may be still good, so that the chances of success later may not become worse, and safety be insured to the patients.

Galezowski. *Del influences des iritis et des choroiditis sur le developpement des cataractes.* *Rec'd. Ophth.*, Feb., 1882. The lens is nourished from the aqueous humor. If disease of the uveal tract affects the latter, the nutrition of the lens

suffers. Galezowski discusses the cataracts which result from this; he calls them "choroiditic cataracts," and sub-divides them into four classes.

Choroiditic cataracts, more strictly speaking glaucomatous cataracts; cataracts resulting from detachment of the retina; and cataracts from retinitis pigmentosa, as the latter disease is only due to choroidal changes.

Goldzieher. The relation between opacities of the vitreous and the choroidal affection. *Pesth. Med. Chir. Presse*, March 4, 1882. The vitreous body does not derive its nourishment from the chorio-capillaris, but from the ciliary body; more exactly, from the blood-vessels of the ciliary processes. Inflammations of the former membrane are therefore rarely attended by opacities of the vitreous; of the processes, almost always. In the serous form of choroiditis, which has its most characteristic exponent in specific choroiditis, dense and copious exudations into the vitreous are the rule. The blood-vessels nourishing the vitreous belong to the supra-choroid, and are surrounded by numerous nets of nerves and ganglion cells. The inflammatory process being conducted through these from the ciliary nerves, explains the rapid and extensive nutritive disturbance of the vitreous, as it is observed in sympathetic ophthalmia, when it manifests itself early in the form of dense opacities of the vitreous.

Angelucci. Contribuzione allo studio dell'embolia dell'arteria centrale della retina. *Gaz. Med. di Roma*, March, 1882. *Embolism of both temporal branches of the central retinal artery*. In the upper branch the embolus was situated at the first fork of the artery, close to the edge of the disc; in the lower, a little farther down and beyond the beginning of the nasal branch. The amaurosis had been sudden, and included the whole field of vision except a small triangle outward. Two months later the two arteries could scarcely be traced beyond the emboli. The return of large hemorrhoids and hypertrophy of the left ventricle are assigned as the cause. (Dantone.)

Aiken, Chas. *Neuro-retinitis from blow on forehead*. *Brit. Med. Journal*, February 4, 1882, p. 157. Patient was thrown out of trap, fell on right side, and was insensible for six hours. Had vomiting, epistaxis, and severe headache. On fourth day found he could not see with O. D., and was brought to Liverpool Eye Infirmary. He could not read Jaeger 20. Central vision and inner field quite lost. Optic disc and retina extending to outer margin of macula, much swollen and of milk-white color, veins engorged, arteries partially hidden; macula blood-red, apparently

enlarged and triangular in shape, apex inward. No hemorrhages, O. S. normal. Ophthalmoscopic examination made four months later showed the optic nerve white—"remains of pigmental displacement" (sic),—arteries small, veins irregularly narrowed. Region of macula presented "washed-out looking" patches on a deeper red ground. No perception of colors. Perception of light in outer field. No central vision. Muscles all acted normally. Pupil sluggish. Sensation normal. (Fitzgerald.)

Denissenko. *A remarkable case of hemorrhage in the eye*. *Wien. Med. Presse*, No. 1, p. 14. The globe had been squeezed by an impinging piece of wood, producing dislocation of the lens. A peculiar red spot was discovered with the ophthalmoscope at a retinal blood-vessel, which became perceptibly paler when pressure was exerted upon the globe; the blood-vessel, whether artery or vein could not be determined, seemed to enter this spot. Diagnosis: Aneurism or varix of this blood-vessel.

Hirschberg. *On amblyopia from iodoform intoxication*, Sitzungsber, d. Berl. Med. Ges., March 15, 1882. C. f. a., vol. vi, p. 93. In a young girl of 16, upon whom a resection of the hip-joint had been performed, and who had been treated for weeks with iodoform, a central scotoma was observed, the visual field being otherwise normal, and no ophthalmoscopic change visible. $V = \frac{1}{2} \frac{1}{5}$. After removal of the bandage, V rose within eight days to one-half.

Del Monte. *Treatment of detachment of the Retina*. *Atti dell' Ass. Ottalm. Ital.*, Sept., 1881. *Ann d' Ottalm*, vol. x, 6. Artificial leeching is useless in old cases—in recent ones even injurious. The effects of injections of pilocarpine should not be overrated. In favorable cases the effect becomes apparent after the first injection. (Dantone.)

Schöler. *Cases of hemianopic defects*. *Annual Rep. of his Ophth. clinic for 1881*. Peters, 1882, p. 30. ff. 1. Left sided homonymous hemianopia from syphilis; partial recovery. Diagnosis: gumma between the chiasm and beginning of the optic nerve. 2. Heteronymous temporal hemianopia in a person of 25 with normal field of vision; without any apparent cause, only heredity; no cerebral symptoms. After the use of iodide of potash, slight change in the boundary line of the visual field. Later, incipient atrophy of the optic nerve was observed. 3. Left-sided hemianopia in course of recovery; cause, syphilis. Rapid improvement under inunction.

Weinberg (Hirschberg's clinic) *on Diathetic retinitis*. C. f. A., vol. vi, p. 65. 1. Retinitis in glyco-

suria and albuminuria. In two cases there were very characteristic changes in the fundus. No choked disc, numerous groups of shining white patches, though they did not show any stellate arrangement. 2. Retinitis from chronic lead-poisoning; a, in a type-moulder. Amblyopia of the right eye. Fingers counted at 8. Normal field of vision in both eyes. The ophthalmoscope showed neuro-retinitis, numerous white punctiform spots in the retina, besides minute hemorrhages, perceptible thickening of the walls of the arteries. b, in a porcelain glazer. Diffuse retinitis with central scotoma. (Recovery).

Wood-White (Birmingham). *Embolism of arteria centralis*. Re-establishment of circulation witnessed with the ophthalmoscope. Ophth. Rev., vol. i., No. 3, January, 1882, p. 49. A young man, æt. 31, the morning of his visit to the hospital, perceived a cloud pass before his right eye, and in a few minutes the vision in this eye was totally lost. With the ophthalmoscope the fundus presented the characteristic appearances of embolism of the central artery.

There was not the slightest perception of light. W. made pressure with his finger on the globe for the purpose of ascertaining whether there was any pulsation of the vessels, but without results. On repeating the pressure, he was surprised to see the circulation suddenly re-established. The patient exclaimed that he could see. $V = \frac{2}{10}$. Field of vision slightly contracted in upper part. This continued. Two days later all œdema of retina had disappeared. $V = \frac{2}{10}$. No history of rheumatism, scarlatina, or syphilis. Cardiac examination showed marked impulse and slight systolic bruit at apex. W. thinks it was most probable that the embolus was lodged in the retinal artery at its point of bifurcation, and that not unlikely the pressure applied to the globe may have assisted in dislodging it, and that it passed forward to some peripheral portion of the retina.

Mandelstamm, E. *Injury of both eyes by a pistol-ball*. C. f. A., vol. 6, p. 9. It entered at the right temple, i. e., eyebrow, and passed out at the left temple near the beginning of the hair. Right side, ptosis, diminution of mobility upward and outward. Amaurosis: the ophthalmoscope showed detachment of the retina and rupture of the choroid above. Left side, no paralysis, detachment of the retina, also a rent in the choroid, and a small one below. Fingers counted at 8. Total loss of the sense of smell.

Mayerhausen. *Cases of visual disturbance after injuries of the skull*. C. f. A., vol. 6, p. 44. Fall upon the left supra-orbital region; unconscious-

ness, profuse epistaxis. Four weeks later atrophy of optic nerve, arteries much contracted, veins about normal, amblyopia, scotoma upward and outward. Diagnosis: Fracture of the base of the skull, affecting also the roof of the orbit resp. the optic canal; compression of the inner lower fibres of the optic nerve.

Mengin (de Caen). "*Observations Cliniques*." Rec. d'Ophth., January, 1882. Reports two clinical cases. 1. Detachment of the whole lower half of the retina, due to an injury, complicated with a rent in the cornea, paralysis of accommodation, as well as the sphincter and pupil, and retinal hemorrhage. Recovery in two months. The author advises iridectomy in detachment of the retina from choroiditis in myopia. 2. Foreign body in the choroid—traumatic cataract; a reddish stone visible upon the choroid after extraction, and borne well; $V = \frac{3}{10}$; large scotoma corresponding to the foreign body.

Oeller. *A splinter of wood* (C. f. A., vol. vi., p. 18) 8 mm. long, in the eye for $1\frac{1}{2}$ years without causing any reaction, as it probably had lain parallel to the longitudinal axis of the globe, behind the upper edge of the external rectus; then in consequence of an inflammation it had placed itself at right-angles to its former position, had penetrated the globe, produced irido-choroiditis, and was found when extracted 8-9 mm. behind the outer edge of the cornea, at the upper edge of the external rectus, perpendicular to the longitudinal axis of the globe. Preservation of the globe and some vision.

Buzzard, J. *On ophthalmoplegia externa, in conjunction with tabes dorsalis, with remarks on gastric crises*. Brain. April, 1882, pp. 34-35, 1 F., 25, double ophthalmoplegia externa, with partial mydriasis (pupils 4-5 mm.), gastric crises, paroxysmal limb-pains, absence of knee reflex, etc. Syphilis at æt. 17, 2 m., 36. Pains for five years. Decided tabetic symptoms six months, followed by ophthalmoplegia externa, quite complete; deafness and dysphagia. No optic atrophy. Death after attacks of dyspnœa. Neither of the sixth nerves nor L. third nerve could be found; other cranial nerves normal. Atrophy of nerve elements with dilatation, plugging, and rupture of minute vessels, at nucleus of origin of 6th nerve. Advanced degenerative changes in posterior columns of cord. Nuclei of the bulbar nerves normal. (Histological examination by Dr. Brevan Lewis.) Comments on the cases.

Conti thinks he has observed a special form of *iritis from malaria* in himself and others. Atti dell. Assoc. Ottalm. Ital., September, 1881. Ann. d'Ottalm., vol. x, 6.

Ely, E. T. Illustrative cases of disease of the eye, arising from affections of the teeth. N. Y. Med. Record, March 11, 1882. E. relates the following cases in which he believes the ocular troubles to depend on diseased teeth. Case 1. Paresis of orbicularis muscle, irregular spasm of ciliary muscle, monocular diplopia. Case 2. Paresis of R. int. rect. and ciliary muscles. Case 3. Partial paralysis of 3d nerve. Case 4. Inflammation of conjunctiva and sclera. In all these cases, the eye troubles disappeared immediately on correction of the dental difficulty.

Possadsky. Pathological changes in the retina in some constitutional diseases. Diss., St. Petersburg, 1882, 27 pages. The author reviews his pathological investigations as follows: 1. In all forms of typhoid fever there is hyperæmia of the retina. blood-vessels, and granular opacity of the third, fifth, seventh, and ninth retinal layers (of different intensity in the different kinds of fever). 2. In chronic pneumonia: hyperæmia, hypertrophy of the connective tissue, granular opacity of the third, fifth, and seventh layers, and occasional pigmentation of the stroma and the ganglion cells. 3. In croupous pneumonia: serous infiltration of various parts. 4. In peritonitis: hyperæmia, infiltration of the tissue with white blood corpuscles, and opacity, and swelling of the third, fifth, and seventh layers. 5 and 6. Meningitis and pyæmia, hyperæmia with extravasation blood-corpuscles, infiltration of the tissue, opacity of third, fifth, and seventh layers (less marked in pyæmia). 7. In uræmia: hyperæmia with extravasation, cellular infiltration of the tissue, slight haziness of the nervous elements. When the ureters were ligated: serous infiltration of the retina. 8. In chronic alcoholism: hyperæmia with extravasation and cellular infiltration, hypertrophy of the connective tissue, coarse granular opacity of the third, and fine granular opacity of the fifth and seventh layers. 9. In jaundice from cirrhosis of the liver: hyperæmia, hypertrophy of the connective tissue, and fine granular opacity of third, fifth, seventh, and ninth layers. 10. In pleuritis with pericarditis: no changes in the retina.

Velardi and Rebozzi, who live and practice in malarious regions, have observed ocular affections which could never be brought into direct connection with the miasm. Atti dell' Assoc. Ottalm. Ital., Sep., 1881. Ann. d' Ottalm., vol. x., 6. (Dantone.)

CORRESPONDENCE.

EDS. MED. AND SURG. REPORTER:—

I find the following among my clippings from "Notes and Queries," 1857. It may be of interest to your readers.

Surgical Operations under Chloroform, &c.—Has the following passage been "noted" in your pages? If not, it would be curious to non-medical readers, like myself, to know whether opium, or what is supposed to have been made use of more than two hundred years ago by the "old surgeons," "who, ere they show their art, cast one asleep, then cut the disease's part," &c.; and whether the use of ether, and subsequently of chloroform, in surgical operations, is merely a revival in these enlightened days of some heretofore forgotten practice of the "dark ages," or whether it is really something new?

Women beware Women, tragedy, by Thos. Middleton, first printed 1657, Act IV., Sc. 1:

"*Hippolito.* Yes, my lord,
I make no doubt, as I shall take the course,
Which she shall never know till it be acted;
And, when she wakes to honour, then she'll thank me for't.
I'll imitate the pities of old surgeons
To this lost limb; who, ere they show their art,
Cast one asleep, then cut the disease's part;
So, out of love to her I pity most,
She shall not feel him going till he's lost;
Then she'll commend the cure."

S. H. H.

CHARLES McSHAINÉ, M. D.

Charleston, West Va.

NEWS AND MISCELLANY.

Philadelphia Polyclinic.

The Dispensary of the Philadelphia Polyclinic and College for Graduates in Medicine, has in two weeks past treated 397 patients, including nearly 100 surgical cases.

Philadelphia County Medical Society.

At a Clinical Conversational Meeting of the Society held on Wednesday, March 21, 1883, Dr. De F. Willard related a case of impaction of feces, and showed the intestine. Dr. G. W. Vogler exhibited a specimen of aneurism of the arch of the aorta, and a specimen of renal abscess. Dr. R. G. Curtin narrated the particulars of an unusual case of hemorrhagic variola. Dr. E. T. Bruen spoke of a case of phthisis with great local thickening of the pleura, simulating circumscribed pleural effusion. Dr. J. C. Wilson showed strips of membraniform exudation removed from the chest of a child suffering from purulent pleural effusion.

The New York Code.

An association for the purpose of upholding the old code of medical ethics, and resisting any modification of this code that does not emanate from the body in which it originated, has been formed, and held its first regular meeting at the hall of the Academy of Medicine, New York City, on Friday evening, March 23. Among those interested in the movement are such leading men as

—A quack castrated a man, and afterwards made amends by taking his wife and living with her in open adultery.

Austin Flint, Sr., Austin Flint, Jr., T. Gaillard Thomas, Alonzo Clark, Willard Parker, Thomas M. Markoe, Lewis A. Sayre, Frank H. Hamilton, Isaac E. Taylor, William T. Lusk, Samuel S. Purple, Abram Du Bois, J. W. S. Gouley, John H. Hinton, Stephen Smith, J. Lewis Smith, Jared Linsly, Nathan Bozeman, Henry D. Noyes, Richard H. Derby, F. D. Weisse, J. Williston Wright, Octavius A. White, John G. Adams, and William J. Morton.

University Post-Graduate Instruction.

The post-graduate medical instruction arranged by the medical faculty of the University of Pennsylvania will embrace four courses of eight weeks each. The first or spring course will begin on the 9th of April; the second or fall course will begin on October 1; the third course will begin on December 1; and the fourth course will begin on February 1, 1884.

The post-graduate instruction includes the following branches: Clinical medicine and physical diagnosis, by Professor Pepper and Dr. Bruen. Renal diseases, with practical examination, by Professor Tyson. Nervous diseases and electrotherapeutics, by Dr. S. Weir Mitchell and Dr. Sinkler, at the Orthopaedic Hospital. Clinical surgery, by Professor Ashhurst and Dr. White. Ophthalmology, by Dr. S. D. Risley. Dermatology, by Professor Duhring. Otolaryngology, by Professor Strawbridge. Gynecology, by Dr. F. B. Baer. Operative surgery, by Dr. White. Clinical and operative obstetrics, by Dr. E. Richardson. Laryngology, by Dr. Seiler. Diseases of children, by Dr. Keating and Dr. Starr. Microscopy and pathology, by Dr. Formad. In addition the classes are permitted to attend the general and special clinics of the University, and such didactic lectures as do not interfere with the post-graduate instruction.

Jefferson Medical College—Alumni Meeting.

The annual meeting of the Alumni Association of Jefferson Medical College took place on Saturday, March 31, when the following officers were elected for the ensuing year: Professor S. D. Gross, President; Drs. Ellwood Wilson, Addinell Hewson, R. J. Levis, and W. W. Keen, Vice-Presidents; Drs. T. H. Andrews and R. J. Dunglison, Secretaries; Dr. Nathan Hatfield, Treasurer; and Dr. Henry G. Landis, of Columbus, Ohio, Orator.

Dr. J. R. Weist, of Richmond, Ind., delivered the annual address, taking for his subject "The Evolution of a Doctor." At the banquet, a large number of well-known medical men were present. Dr. Weist, together with Professor S. D. Gross, Provost Pepper, of the University of Pennsylvania, and Dr. Nathan L. Hatfield, the oldest living graduate of Jefferson College, as the principal guests of the evening, occupied a small table, the other guests, over 100 in number, not being seated. Among the others present were Professors Henry O. Chapman, Da Costa, Brinton, Pancoast, Bartholow, and Thompson, and Drs. Addinell Hewson, Dunglison, Woodbury, Ellwood Wilson, Andrews, Barton, and A. M. Shaw, of the Middleton Insane Asylum.

A marble bust of the late Professor Joseph Pan-

coast, by Ewing, was presented to the Alumni by Professor William H. Pancoast, and was received on the part of the Association by Professor Gross.

Jefferson Medical College.

The annual commencement of the Jefferson Medical College took place in the Academy of Music on Monday, April 2. At 11:40 a. m., the Trustees, Faculty and graduating class marched in procession from the College to the Academy of Music. After prayer by the Right Rev. Cortlandt Whitehead, D. D., the Hon. James R. Ludlow conferred the degree of Doctor of Medicine upon 227 graduates. The following prizes were then awarded:

1. A prize of \$100, by Henry C. Lea's Son & Co., for the best Thesis, to Charles Pottberg, of New Jersey; with honorable mention of the Thesis of Henry D. Fulton, of Pennsylvania; Henry B. Allen, of Kansas, and Charles L. Weed, of Pennsylvania.

2. The "Robley Dunglison Prize" of \$50, by Dr. Richard J. Dunglison, for the best Essay on the Localization of Cerebral Functions, to Irvine Moore Flinn, of Delaware; with honorable mention of the Thesis of Edward M. Furey, of Pennsylvania.

3. A prize of a Gold Medal, by R. J. Levis, M. D., for the best report of his Surgical Clinics at the Pennsylvania Hospital, to Moses S. Simpson, of Ohio.

4. A prize of a Gold Medal, by Thomas G. Morton, M. D., for the best report of his Surgical Clinics at the Pennsylvania Hospital, to Emil Hertel, of Delaware; with honorable mention of the Thesis of Henry L. Uhler, of Ohio, and Henry Baldwin, jr., of Ohio.

5. A Case of Instruments, for the best Essay on a subject pertaining to Obstetrics, etc., to John L. Dickey, of West Virginia; with honorable mention of the Thesis of Charles H. Ott, of Pennsylvania.

6. A Gold Medal, for the best Essay on a subject pertaining to the Practice of Medicine, to Orville Horwitz, of Pennsylvania; with honorable mention of the Thesis of Henry W. Johnson and David R. Summy, of Pennsylvania, and Lester C. Pratt, of Ohio.

7. A Case of Instruments, for the best original research in the Chemical Laboratory, to Robert Morrison, of Pennsylvania; with honorable mention of the Essay of Nathan C. Wallace, of Pennsylvania.

8. A Case of Instruments, for the best original research in the Materia Medica Laboratory, to Robert E. Moss, of North Carolina; with honorable mention of the researches of Ripley C. Hoffman, of Iowa, and Randall N. Bartleson, of Pennsylvania.

9. A Case of Instruments, for the best Essay on a subject pertaining to Physiology, to William A. Westcott, of New Jersey.

10. A Case of Instruments, for the best Essay on a subject pertaining to Surgery, to George V. Hale, of Massachusetts; with honorable mention of the Thesis of Samuel Wimpleberg, of New York, and Richard B. Wetherill, of Pennsylvania.

Dr. Addinell Hewson, on behalf of the Alumni, presented to the Board of Trustees a marble bust

of the late Emeritus Professor of Anatomy, Dr. Joseph Pancoast.

The Valedictory address was delivered by Professor J. M. DaCosta.

Items.

—A School of Pharmacy for Women has been opened in Louisville, Ky.

—Dr. Hewson, of London, says that the sparrow may have small-pox and propagate the disease.

—A pharmaceutical association has been formed in the Black Hills, Dakota. The organization has its headquarters at Deadwood.

—A sensible bill has been introduced in the Minnesota Senate, providing for seats for all female employees in factories or stores.

—The leaves of *euphorbia pilulifera*, L., a plant growing in Queensland, are reported to be a sure remedy for asthma and other affections of the chest.

—Traube recommends sugar of milk as a mild and trustworthy laxative, in doses of two or three drachms, dissolved in half a tumbler of warm milk, taken before breakfast.

—A bill has been introduced in the Michigan legislature, providing that the bodies of unclaimed paupers shall not hereafter be sent to the Medical College at Ann Harbor for dissection.

—Dr. Meredith, in the *Birmingham Medical Review*, recommends oil of peppermint as an external application for allaying the neuralgic pain so often complained of in cases of herpes zoster (shingles).

—A busy doctor sent in a certificate of death the other day, and accidentally signed his name in the space for "Cause of death." The registrar says he wishes the profession would be as accurate generally.

—For warts. Prof. Unna recommends the continuous application of mercurial ointment containing five per cent. of arsenic, or a plaster containing in each 0.2 square metre (eight square inches), ten grams (154 gr.) of arsenic, and five grams (77 gr.) of mercury.

OBITUARY NOTICES.

DR. ROBERT H. ARCHER.

Dr. Robert H. Archer died at his residence, in Darlington, Md., on Saturday, March 10, 1883, aged about sixty-nine years. Dr. Archer graduated in medicine from the University of Maryland in 1835, and after practicing in various places, finally settled in Darlington over two years ago, where he has been living and practicing his profession ever since.

Dr. Archer required no death-bed preparation for the ending of life. He lived daily in a constant state of preparation. He was a good man, in every sense of the word.

WILLIAM HOLME VAN BUREN, M. D., LL. D.

Professor William H. Van Buren died in New York City, on March 25, 1883. Born, April 5, 1819, of a line of medical ancestors, in a family

of refinement and education but devoid of wealth, Dr. Van Buren reached a position in the profession of the highest distinction. He entered Yale with the class of '38, but did not graduate; yet the college, in recognition of his literary attainments and distinguished position, decorated him with the honorary degree A. M. in 1866, and later in 1878, conferred upon him the highest title in her gift, LL.D. The University of Pennsylvania, in 1840, graduated him in medicine after his return from a tour in the Paris hospitals. He then served in the army until 1845, in which year he came to New York to assist the late Valentine Mott in the work of his clinique in the medical department of the University of New York. His death was due, indirectly, to apoplexy, which occurred in the spring of 1882; directly, to degenerative changes about the injured cerebral focus, changes which set in with the beginning of the present year. He appreciated the approach of death, and wished for it.

QUERIES AND REPLIES.

MESSRS. EDS.—Was it a violation of the Code of Ethics for Dr. N. to propose to do the jail practice of a community for seventy-five dollars, after ascertaining that thissum was the average cost per annum? If it is, please designate the article or section, and reconcile it with your decision in the case of January 20, 1883. T. T.

Ans.—It was not a violation under such circumstances; it would have been contrary to the spirit of the Code to have offered to attend for a decidedly less sum than previously paid.—EDS. REPORTER.

MARRIAGES.

MONROE—McCUTCHEON.—March 8, by Rev. J. L. Leeper, at the residence of the bride's mother, George M. Monroe, M. D., of New Bristol, Ohio, and Miss Mollie McCutcheon, of Claysville, Pa.

PARKE—SIDEBOTHAM.—On Wednesday evening, March 7, 1883, by Rev. I. Newton Ritner, George T. Parke, M. D., and Mrs. Ella Sidebotham, both of this city.

KETCHAM—ODELL.—In this city, on Tuesday, March 27, at the residence of the bride's parents, by Rev. F. F. Ellenwood, D. D., Dr. T. V. Ketcham, of Stamford, Conn., to Ida B., only daughter of J. D. Odell.

McCOY—ELLISON.—At Summit Ridge, Del., March 14, by Rev. Irwin Lewis Caton, J. Cresap McCoy, M. D., of New York city, and Lizzie B. Ellison, daughter of Mr. Jonathan Ellison, (deceased).

DEATHS.

GOODRICH.—In Brooklyn, Wednesday, March 28, Charles, S. Goodrich, M. D.

HART.—At the residence of his father, in Old Saybrook, Conn., on Thursday, March 29, Dr. George Hart, late of New York city, aged 35 years.

HEADLEY.—In New York, Saturday, March 31, at his late residence, William S. Headley, M. D.

WILCOX.—Dr. M. A. Wilcox, of Halifax county, N. C., one of the oldest physicians in North Carolina, is dead.

KING.—In New-Brighton, S. I., on Sunday evening, March 18, C. Henry King, M. D., physician-in-chief of the Sailors' Snug Harbor, in the 40th year of his age, of pneumonia.

MARTIN.—At Omph-Ghent, Madison county, Ills., on Thursday, March 22, 1883, Dr. Wm. A. Martin, aged 58 years and 20 days.

ARCHER.—In Darlington, Md., Saturday, March 10, 1883, Dr. Robert H. Archer, aged 69 years.

EPIDEMIC DYSENTERY, AS IT OCCURRED IN NEW GARDEN, ETC., IN 1824.

BY E. MICHENER, M. D.,

Of Toughkenamon, Chester County, Pa.

The summer of 1824 was rendered memorable, in this portion of Chester county, by the sudden irruption of a violent epidemic dysentery, the history of which does not appear to have been written. After the lapse of sixty years, I find myself the only surviving medical witness of its fearful ravages. With the aid of a few brief notes, and a memory retentive of the more impressive events of long ago, I will endeavor to preserve a short history of the disease, as I witnessed it. My report must necessarily appear in the tawdry dress of an egotist.

I can not now recall the meteorological features of the season. But it may not be irrelevant to record the fact that there was a destructive tornado in the near vicinity, July 6, just about the time of its commencement. (See History of Chester County, p. 458.)

The epidemic of 1824 originally occupied a belt little over two miles wide, and ten to twelve miles in length, including the south-western part of Kennett, the southern parts of New Garden, Londongrove, and New London (now Franklin) townships. Indeed, traces of it were reported almost from the Delaware to the Susquehanna. As the season advanced, there were a few extra limital cases. But so well were its limits defined, that while numerous cases, and several deaths, occurred in the Toughkenamon Valley, there was

only one solitary and very slight case of it north of the hill.

It is humiliating to acknowledge that the recent removal of the late Doctors John Ross, father and son, had brought forward several rival claimants for a pittance of their extensive practice, and whose jealousies had closed the way for friendly and professional intercourse among them.

Dr. Palmer Chamberlain was located at New Garden; Dr. B. I. Pennock at Londongrove; Dr. Robert Allison near Chatham; Dr. Josiah Ankrum at Jennerville, and the writer at Prestonville. Drs. Allison and Pennock were out of the district and saw only a few cases. Dr. Ankrum was the only one I met in consultation. We often visited each other's patients. More than this, little was known of each other's opinions and practice. The highest rate of mortality was certainly in New Garden; more especially in adults. It is due to Dr. Chamberlain to say that the disease began in his district, and, as I believe, was most general and most malignant there. In evidence of this, the records show that during the three months of its prevalence there were more than sixty of its victims buried in the New Garden grounds, three of whom were my patients.

I confess to the charge of being *radical* in the treatment of acute inflammatory diseases. It has been my life motto, "It is easier to crush the egg, than to kill the envenomed monster it would produce."

During a space of nearly three months, I visited about thirty patients daily, often several in the same family, and can conscientiously—not boastingly—declare that during this period I lost only two patients over *nine years* old, both of

whom were in bed when attacked with dysentery. The sequel will show a much higher mortality in children.

These notes will, I think, show the propriety of considering the disease as it appeared in *adults* and in *children* separately.

AS IT APPEARED IN ADULTS.

It is probable that sporadic cases of dysentery, which may occur at any season, generally in autumn, may often be a primary *colitis*, from incidental causes. But when it assumes an *epidemic* character, as in this instance, I apprehend that it has a broader and deeper origin.

The prominent symptoms of this epidemic, as I interpreted them, indicated a *primary congestion*, beginning, perhaps, in the liver, and speedily extending to the entire portal system, and if left to its course, rapidly ending in *acute inflammation* of the viscera involved. The truth of these general pathological views is best determined by the success of treatment based upon them.*

I will illustrate this by cases.

CASE 1. 1824-8-28.—Was called at an early hour this morning to see M. S—, a young woman aged 18, of healthy parents, and possessing a vigorous constitution.

She had a heavy chill last evening, with its accompaniments of pain in the head and back, followed by fever, sense of fullness, weight, and a burning sensation rather than pain, especially in the hepatic and gastric regions. Later she had sick stomach and diarrhoea.

Twelve hours after the chill, I found her with the symptoms aggravated. High fever, skin hot, pulse full and frequent, throbbing pain in the head, distressing sickness of stomach without vomiting. The abdomen was generally tense and quite tender on pressure, especially in the right hypochondrium, with pain in the latter locality. She was now having frequent mucous stools, with tenesmus and streaks of blood—the work of twelve hours.

Was this an *ordinary form of dysentery*? Was it a *primary colitis*? I could not diagnose it so.

*Hunger is seldom counted a *morbid symptom*. Here it was, in some cases, the first sign noticed.

A. B—, a very delicate woman, felt unwell and yet inclined to take an ordinary breakfast. Two hours later I found her taking a lunch. She said that she felt so hungry she could not refrain. She was a sick woman long before night.

I met M. T— one morning at a neighbor's and inquired for her three-year-old boy. She replied, "Right well. He ate a very hearty breakfast, and in an hour after, came in calling for something to eat." It was not a new story. I told her to go home and she would find him sick. She did so. In four days he was dead,

True to my convictions, I immediately bled her to $\frac{3}{4}$ xviii, in a sitting position, with great relief to her sufferings, even while the blood was flowing. This was immediately followed by hyd. submur., grs. xx., and sulph. magnes., a tablespoonful in an hour after, and repeated every hour until *copious stools have been obtained without tenesmus*. This was a *sine qua non*.

This practice was based upon many previous observations, as well as on theory. I had found that in well-developed cases relief was preceded and could only be obtained by a copious discharge of a dark pultaceous mass without tenesmus or griping pain. In a few instances, this occurred almost spontaneously. The first case I saw, an eight-year-old boy, I found on the porch, sitting over a pile of more than half a pint of such stool. He required very little medicine. Nature had nearly done the work.

29th. As I had anticipated, the medicine of yesterday had procured several copious and free evacuations, with almost entire relief of suffering through the day. After an hour's sleep, she awoke with some return of former symptoms, though in a much mitigated form. The blood drawn yesterday had formed a thick buff, which is contracted to the size of a half dollar; but this is now all figee.

The cause appearing not fully removed, I repeated the course. Took $\frac{3}{4}$ xij. of blood, with marked relief to the remaining suffering, with the calomel and salts, as directed yesterday.

30th. The medicine procured free evacuations, though less abundant, and afforded entire relief. She had slept well during the night, and now expresses herself quite comfortable. A Dover's powder at night, with rest and a careful diet, was all the attention she required. Convalescence was rapid and uninterrupted.

I give this as a typical case; others of similar character might be added. Owing to obvious causes, this heroic treatment could not be employed in all cases, mostly resulting in prolonged treatment and increased exhaustion.

Strange as it may seem, my patient lived to marry and raise a family of children, who could rise up and call her blessed.

CASE 2. While the preceding case was still under notice, I was called to attend another, under somewhat less favorable conditions. Catharine, the wife of D. S—, and the mother of nine children, naturally of a good constitution, but much broken by early and rapid child-bearing, and the burdens incident to a large family, was attacked with the prevailing disease early in the

evening of the 1st of 9th month. I was sent for early in the morning, but being absent from home all day, did not see her until after nightfall—some twenty-eight hours after the attack. The symptoms were so similar to those already given that I need not repeat them. They were, however, more violent, and progressed more rapidly.

I found the entire abdomen tense, painful and intolerant of pressure. The termina and tenesmus almost constant. The pulse was frequent, irregular, and feeble, with short and sighing respiration. She had severe pain in the head, with a hesitancy in answering questions, and sometimes incoherence. She had become despondent, and objected to anything but to die. Such a case I had not seen.

I gave my opinion frankly to the anxious husband that it was not probable that any means could save her. If anything was done, it must be *prompt and severe*; and if it failed, might even *hasten her death*. The immediate reply was, "Doctor, you know that I have entire confidence in you; do just what you think best." Who would betray such confidence? My mind was made up.

I ordered a hasty warm bath prepared, and in the interim, bled her to $\bar{3}$ xvij, and immediately gave her hyd. submur. $\bar{3}$ ss., ipecac $\bar{3}$ j. M. ft. pulv.; then placed her in the bath. The bleeding had a very soothing effect, and when she got into the water, was comparatively easy. While still in the bath, the emetic produced two or three free operations. She was then placed between blankets, with warm covering and a hot brick wrapped in a wet cloth to her feet. I then left for the night, with directions to give her a mild anodyne and stimulant mixture after each operation of the calomel.

The morning found my patient weak and exhausted, but indeed less so than when I first saw her. After an hour or two of rest, the medicine had produced several very copious stools in quick succession, after which she remained free of pain and inclined to sleep. From this time forward mild opiates and tonics, with good nursing, soon restored her to health.

This bold and decisive practice, as in the former case, was directed to the alone object—to *unload the congested viscera before active inflammation and disorganization should take place*. As the fulfillment of a prophecy is evidence of its truthfulness, so the result in this case is proof of a correct diagnosis. The sequents of the congestion vanished, even in less time than was required to produce them.

When will our physicians learn the practical

lesson, that a patient will recuperate from loss of blood before the assimilative functions have been seriously injured, much more readily and speedily than from anæmia where the whole organism has been exhausted by prolonged disease?

My patient recovered!! She did more!!! In due season she added four more sucklings to the flock, and completed the good old Irish dozen, and lived to a good old age.

In this disease, dysentery was *secondary*—the *sequence of congestion* in the superior viscera of the abdomen—and congestion only means an obstruction of the flow of blood and an accumulation in the obstructed vessels. The indications were plain. The demand for prompt relief was imperative before greater mischiefs should occur. Herein lies the secret of my success. How far other epidemics, or even sporadic cases of colitis, would be amenable to such treatment, I may not decide; but I have used it in the latter form of the disease with satisfaction.

In relation to large doses of calomel as a purgative, I wish to say that I have very frequently administered it in this epidemic, and in other acute diseases, in doses of $\bar{x}$ to $\bar{x}$ grains, with most satisfactory results, and have not cause to regret it. It is scarce more annoying than a smaller quantity, while its power to calm morbid excitement and equalize the disturbed circulation is only second to that of the lancet.

NOTE.—Since this paper was written, Dr. T. has informed me that in conversation with Dr. Chamberlain some years ago about this dysentery, the doctor mentioned that I. M.— had been very bad, and despairing of the case, he gave him an unlimited dose of calomel ($\bar{3}$ j., or more), and next day found that it had produced the happiest effects. His patient recovered.

THE INFANTILE FORM.

While no age or condition was exempt from the malady, its ratio of mortality was greatly increased by what I have termed the "Infantile Form,"—peradventure it was not a *superadded epidemic*. It usually occurred in children from three to four months to as many years—seldom later.

With the few and imperfect notes which I possess, I shall not attempt, at this late day, to give minute details. Usually from two or three to forty-eight hours from the first disturbance of the bowels symptoms simulating *cerebral inflammation* would suddenly appear. Sometimes at the first visit—skin hot, especially of the head; face flushed, eyes red and watery; child very fretful, sometimes with sudden starts and screams. Sooner or later, from two hours to as many days,

the excitement would abate, the skin become cool, the child would become listless and sink into stupor, coma, and death. So rapid were these changes in some cases that several children died on the second day, and without medical treatment. I believe it was always preceded by the bowel disturbance, yet they were often almost simultaneous.

It was under these appalling circumstances that I was called to treat this fatal *nondescript*, under a false garb; and I frankly acknowledge to having lost *fourteen out of the first seventeen* cases in quick succession. I could not learn that others were more successful.

Dr. Ankrim and I had frequently consulted, and often visited patients in company, and it was not without much serious thought and anxious inquiry; but it was one thing to feel that we were wrong, quite another to know and to do the right.

Like the dawn of morning, light comes slowly. Fortunately, an older boy (six or seven years) was passing nicely through a mild attack of dysentery, when he suddenly began to manifest the usual coolness and languor, without having shown the cerebral excitement. I invited Dr. Ankrim to see him with me the same evening. In answer to my inquiry, he replied, "He will die before to-morrow night, just as others have done." I then showed him a prescription which I had just prepared for the boy. His answer was, "If you give that, I will have to see your patient in the morning." It read—

R. Huxham's tincture,	℥ ss.
Elixir paregoric,	℥ ss.
Spirit. nit. dulcis,	℥ ij.

M.—Give a teaspoonful in sugar-water every hour, if awake.

On our morning visit, were rejoiced to learn that soon after the second dose he slept quietly for two hours, and woke up quite refreshed. The stupor had passed off, the skin had become more natural. He was, in fact, quite comfortable, and made a speedy recovery.

I had now *crossed the Rubicon*. I had done more: I had *anticipated*, by a dozen years, the the thrice-repeated discovery of Drs. Abercrombie, Hall, and Gooch, of *spurious hydrocephalus*. Of the value of my discovery I could not yet venture to judge. But I awaited, with much anxiety, the occurrence of another as a *test case*. It soon came. By the careful use of stimulants and tonics in conjunction with evacuants, my patient did well.

After the sad failures which I had experienced, it is with no little pleasure that I can state that

I was now able to reverse the bill of mortality to *three deaths out of seventeen cases*.

In observing these cases, I had constantly noticed the *sunken condition* of the fontanelle. It now became significant to distinguish between the true and spurious cephalic affection. I had often referred Dr. B. I. Pennock and others to this distinctive sign many years previous to the announcement of Dr. Watson in 1843, eighteen years after I had noticed it. Dr. Pennock used to often pass his jokes on me for allowing others to reap the reward of my discoveries, by neglecting to publish them.

An incident of the season: Dr. Pennock, then a young practitioner living at Londongrove, only three miles north of the infected Toughkenamon Valley, had been wondering what was the matter down there. A little babe of C. S.—'s was taken sick in the night, and Dr. Chamberlain sent for in the morning, but he, too, was sick, and Dr. Pennock saw it in the afternoon. Next morning I met the doctor on his way to see the child. I earnestly inquired his views in relation to the disease. He had none to give—he had only seen this child once, and had called on two of Chamberlain's sick in the evening. He had not noticed anything unusual. He did not think the child very ill. It is enough to say that he arrived at ten o'clock to learn that the child had been dead about an hour. This was too much for his sensitive nature. He did not want to see any more New Garden dysentery.

Now, kind readers, you have had the opportunity of knowing the extraordinary advance in the knowledge of pathology, diagnosis, and therapeutics within the past sixty years, may I claim your indulgence? May I remind you that where much is given, much will be required? And let me ask, can you show a better record than I have done, co-ordinate with the improved advantages which you enjoy?

The number of deaths cannot be ascertained. The interments at New Garden, West Grove, New London, and some scattering ones in other grounds, probably reached about one hundred and twenty.

SCIRRHUS CARCINOMA OF THE STOMACH.

BY DANIEL LONGAKER, M. D.,

Of Philadelphia.

[Presented before the Northern Medical Association, February 23, 1883.]

Mr. H., German, married, æt. 48, without hereditary tendencies, was a moderate drinker, never to excess, of such liquors as wines and beer; no venereal history. Was of stout build, weighing

two hundred and forty pounds. Until three and a half years ago, he was in the enjoyment of excellent health. At that time he began to suffer from dyspepsia, manifested by such symptoms as a variable appetite, ravenous at one time, then bad; eructations; flatulency; discomfort, but no pain after eating, or at any time. From this time on, during the following three years, he tried various physicians without relief.

Six months ago he came under the observation and care of Dr. Trautmann, by whose courtesy I am enabled to report the case. At that time there was no decided loss of flesh, or great failure of strength. His countenance was of a pale, yellowish, rather sallow hue. He suffered from nausea after eating, flatulency, and there was slight soreness in the epigastric region. Bowels were costive at times only. Under the use of subnit. bismuth, with aloes and alkaline carbonates, his condition soon became decidedly improved, so much so that he only remained under observation as an office patient for about a month, when, considering himself much better, he did not deem it necessary to seek farther advice. From the peculiar hue of the skin, resembling somewhat that of jaundice, with the presence of a hard, indistinct mass in the neighborhood of the gall-bladder, and the absence of such marked gastric symptoms as would be expected from serious organic disease, cholelithiasis was supposed to be present as a concomitant condition.

His condition of apparent improvement continued only for a few weeks, when, beginning to lose flesh and strength rapidly, he became unable to leave his house. Under the impression that he now had consumption, upon the advice of his friends, he persisted for a short time in the use of an animal oil (dog fat). His gastric symptoms were now aggravated to a marked degree, but with appropriate treatment were soon again controlled. Constipation, with slight diarrhoea, a little vomiting and flatulency were noticed, and now for the first time, about three months ago, he began to have distinct pain referred to the epigastrium. It was never severe or lancinating, and most of the time he was entirely free from suffering. The flatulent distention of the abdomen was more cause of annoyance than the pain. From the presence of a tumor in the region of the pylorus, with symptoms referable to interference with the digestive function and the cachexia, a marked carcinoma of the stomach was diagnosed. This opinion was negated by one of our eminent diagnosticians, who unhesitatingly referred the malignant growth to head of the pancreas.

A short time after this, I observed the following

condition: A tumor, not as large as the hand, having a boggy feel, not tender to pressure, and occupying a position a little to the right of the median line. The ensiform cartilage was prominent, and displaced forwards. The tumor was not movable. There was slight tympanitic distension of the abdomen. He was emaciated and weak. His color presented that clayey appearance, characteristic of cancerous disease. He continued to take food in limited quantities, with no more suffering than has already been stated, until the termination of his life, three days ago. At no time was there vomiting of blood, or evacuation of mælenae. Œdema of the feet and legs appeared about three weeks before death.

Autopsy, thirty-six hours after death: Rigor mortis distinct. The body is greatly emaciated, and almost entirely destitute of subcutaneous fat. The peritoneal cavity contains a small quantity of fluid. The small intestines are normal. The transverse colon is extensively adherent in its middle portion, nothing abnormal in the ascending and descending part of it. The liver is anæmic, pale and slightly diminished in size. Glisson's capsule is thickened and opaque. To the under surface of the liver is found adherent the transverse colon and the pyloric end of the stomach. The gall bladder contains the usual amount of bile. The stomach is not dilated; on the other hand, there is a distinct thickening of its coats. It contains a half pint of semi-fluid ingesta. At the greater curvature, and encroaching closely upon the pyloric orifice, is found a nodular mass, of a hard, tough consistence, larger than a hen's egg in size, but flattened, and showing a tendency to pass circularly around this portion; there is about one-fourth of the circumference which apparently is not yet invaded by the growth, being normal to the naked eye. In a few places, the mass shows signs of commencing ulceration. In limited portions of the mucous membrane the vessels are dilated, a few infarcta are noticed. The duodenum is stained with bile. The pancreas is normal. It is adherent to the pyloric end of the stomach. There is no obstruction of its duct. The kidneys and spleen are normal in size, and of macroscopic appearance. The capsules of the former are easily separated.

In the thoracic cavity a slight adhesion is found to exist between the pleura of the apex of the right lung and the costal investment of that membrane. There is here also a limited catarrhal pneumonia. With this exception, the lungs are normal. The heart is small, the valves are intact, it is filled with soft coagula.

The existence of the tumor in this case, with the marked cachexia, left no room for doubt as to its malignancy, but with the absence of the usual severe and decided gastric disturbance, the question of diagnosis with regard to its location was one of interest.

Flint, in his clinical medicine, referring to the recognition of diseases of the pancreas, carcinoma, among others, frankly states. "As a general statement, they defy diagnosis." "Happily for the diagnostician as well as patients, they are extremely rare in this situation." Even the absence of fatty diarrhoea does not exclude pancreatic disease, though its presence renders it probable.

How the fact of a disease being extremely rare can be a consolation to the diagnostician, I cannot appreciate, unless we practically ignore their existence. But the case under observation may be the rare example, and then, at least, it must be admitted, it is not a consolation when the scalpel reveals a different condition from that which was suspected. Because certain diseases are rare, we are necessarily not familiar with their clinical phenomena, and hence their difficulty of recognition; but the effort to do so is certainly a laudable one, and should even a mistaken opinion be advanced, no disgrace to one's reputation can attach to it. But in case of uncertainty, he who ignores the rare and assumes the existence of the common, will be at least likely to be foiled.

CASE OF OXALURIA.—TREATMENT.—RECOVERY.

BY JOSEPH L. BAUER, M. D.,
Of Saint Louis,
Surgeon to St. Mary's Hospital.

W. W., æt. 34, presented himself to me with the following history: Masturbation had been practiced in youth; had suffered from one attack of gonorrhœa; had always been fond of the opposite sex, and had freely indulged his sexual appetite. For the last two years, had suffered from irritability of the bladder, and frequent micturition; the latter disturbing him both day and night. At certain micturitions he suffered with pain along urethra, and at neck of bladder after urination. Occasionally, a muco-gelatinous discharge exuded from urethra; the urine presented flakes of mucus also. He suffered from hypochondria, indigestion, general pains, constipation, and partial impotency; of late, these symptoms have increased, and the patient, who has read a surfeit of marriage guides, believes he is losing his virility.

A personal examination elicited the following:

Putting and inflamed meatus urethræ; all efforts to pass instruments were resisted by the intense urethral hyperæsthesia; examination per rectum disclosed sensitiveness about neck of bladder and membranous urethra. The prostate gland was tender and slightly enlarged. Urine acid, but presented no pathological conditions. In order to place the urethra and bladder in a condition for examination, the following treatment was pursued:

R. Potass. acetatis,	ʒ iiss.
Ext. buchu fluidi,	ʒ ss.
Ext. hyoscyami,	gr. xij.
Syr. gentianæ,	ʒ j.
Aquæ distil.,	q. s. ad. ʒ vj.

M. D. S.—A tablespoonful every 3 hours.

Besides this a suppository of (10) ten grains of iodoform and five (5) drops of ol. eucalyptol (Lauder), was placed in urethra daily until all sensitiveness disappeared. My opinion was that the constitutional disturbances and impotency were due to urethral hyperæsthesia, brought about by sexual excesses. Accordingly, I introduced a Leroy bulbous bougie, down to the neck of bladder. At the latter point some tenderness was still present. No other abnormalities were discovered. Upon its withdrawal the usual membranous fold was detected four and a half (4½) inches from meatus. Up to this time my patient was improving, and we continued the treatment first ordered. He made a trip to the country, and upon his return informed me that he had a severe attack of RENAL COLIC, resulting in the escape from the urethra of numerous calculeous concretions, which had aggravated his bladder and urethral trouble. Enclosed in a paper, was a specimen of a larger calculus. My friend, Prof. W. B. Hazard, who was present, pronounced them *oxalate of lime*. (A later chemical examination verified this statement). The presence of these concretions directed my attention to his INDIGESTION—which I had ascribed to reflex nervous troubles—and I prescribed five (5) drops of nitro-muriatic acid dilute thrice daily, to be gradually increased to toleration. I also injected bladder with a solution of one and a half (1½) drops of nitric acid pur. to two (2) ounces of water. This treatment had the desired effect. My patient soon recovered entirely.

It was a fortunate coincidence that a large number of these concretions passed with his urine; for he acknowledged the frequent presence of a sandy sediment previously, but had neglected to inform me of the fact. The symptoms pointed to either deep urethral hyperæsthesia from sexual excesses, or to a vesical calculus. The former was verified, but the latter could not be discovered.

by the free use of the sound. Then again, STRICTURE OF LARGE CALIBRE (?) might be responsible for the same mischief, or at least a contracted meatus. The latter indeed existed, but not being an enthusiastic believer in the former view, I placed little stress upon it.

My object in reporting this case is to call attention to the fact, namely, that the oxalate of lime diathesis is more frequent than is generally supposed, and that it is often mistaken for some other obscure difficulties. Thus a prominent gentleman of this city, who had been a sufferer for some years, consulted a REPUTED NEUROLOGIST of New York city, who immediately diagnosed some serious nerve trouble. The patient returned to St. Louis, was placed upon an acidulated carbonic acid and beer diet, and soon recovered his health. In fact, a free perusal of medical literature fails to discover any distinctive discussion of this disease. Walter Coulson, F. R. C. S., England, and Prof. Austin Flint, are the only ones in which references could be found. It would be well for some of our authorities on genito-urinary subjects to devote more space to the description of such affections, which are so liable to be mistaken for other pathological conditions. PERI-NEPHRITIS, for instance, is another one of those renal difficulties which have not received sufficient attention. If I am not in error, Dr. Gibney, of New York, is the first who has directed our attention to the great resemblance it bears at times to the morbus coxarius, and yet none of our great orthopedic surgeons make reference to it. And yet, the disease exists and does simulate hip-joint disease greatly. At some future time I shall be pleased to present the profession with a more exhaustive view of both subjects.

IODOFORM AS A LOCAL APPLICATION IN FISSURE OF THE ANUS.

BY THOMAS HAY, M. D.,
Of Philadelphia.

The value and efficacy of iodoform in fissure of the anus will bring this remedy into general use in the treatment of this painful and heretofore incurable lesion, without operation by the knife or forcible rupture of the sphincter ani muscle.

It is good surgical practice to cure surgical cases without surgical operation whenever it is safe and practicable; and while it is shorn of its brilliancy and éclat, the fact remains the same, and it is not questioned that conservatism in surgery has been steadily gaining ground, and that the boldest operators are those who weigh well the results before operating.

As in cases involving the greatest danger, so with fissure of the anus—if the trouble can be cured by simple means, without suffering to the patient, and in reasonably due time, the operation of cutting, or forcible rupture, is not justifiable, and both these means of radical cure must give way to the more simple, if such may exist. With the experience I have had in the use of the local application of iodoform in cases of fissure of the anus, I am encouraged to bring the value of this remedy to the notice of the profession in these cases. In their treatment with this remedy, the alvine evacuations should always be maintained in a soft condition; the bowels should never be allowed to become constipated or relaxed; the anus, and parts involved by the fissure, should be kept constantly clean and free from deposit and dry incrustations; and with one or two evacuations a day, the case may be speedily cured by the local use of iodoform. It may be dusted, in *very fine* powder, upon and into the fissured parts, or applied in the form of ointment or suppository. The application of the simple powders, if properly prepared, three or four times a day, after each evacuation, and in the intervals, is often sufficient. In some cases, however, the undiluted powder—although thoroughly powdered—causes some pain. In such, the iodoform may be mixed with powdered gum acacia, if a powder be preferred, or may be made into an ointment with vaseline, or suppository with the oil of theobroma. Balsam of Peru, carbolic acid, and oil of peppermint, will moderate the intensity of the iodoform odor; but this can hardly be requisite for application in this situation. The application of the remedy may be followed by a little smarting, but soon after its use the sensibility of the parts becomes benumbed, and even defecation may go on without consciousness, so far as concerns the development of pain during or after the process. That this remedy applied as above directed and indicated will cause complete unconsciousness of the act of defecation, I doubt—I have never witnessed such result in any case that has come under my notice, and still the benumbing influence of the remedy is decidedly potent. As in applications to the conjunctival surfaces of the eyelids, the first and most important factor in the successful and painless use of the remedy consists in the proper preparation of the powder. It should be made *very fine*, and not the smallest crystal be allowed to remain unpowdered. The neglect of this precaution when applied to the eye has caused the most painful inflammation of the ocular and palpebral conjunctiva; and applied thus imperfectly

powdered to the anus, would likewise cause intense suffering, and as in eye practice, would be abandoned, and declared to be dangerous and valueless, if intelligence did not bring relief.

HOSPITAL REPORTS.

PHILADELPHIA HOSPITAL.—A CLINICAL CONFERENCE.

BY JOHN M. KEATING, M. D.

Reported by W. A. EDWARDS, M. D., Assistant to Professor Clinical Medical University of Pennsylvania.

The Rachitic Diathesis.

GENTLEMEN:—As has been my custom I propose to take up for your consideration to-day, one of the four diseases that are termed diathetic, those affecting the nutritive process, either from a constitutional, or an acquired taint, developing at times almost immediately after birth, because of the intensity of the inherited potent cause or again waiting for some future time when the infant shall be placed under circumstances adverse to its proper growth and development.

Rachitis or *Rickets* is a disease of the general nutritive process, attended with structural changes most conspicuous in the bones; this consists in an abnormal increase in the cartilaginous and embryonic substance of the osseous tissue.

As a rule rickets is noted no earlier than two or three months, and then its first manifestation is generally the nodules at the chondro-costal articulations, the so-called beaded ribs; after the age of two or three years the number of those affected with rickets become gradually less. Occasionally the disease is said to be congenital; such children die of atelectasis or of trismus. You have all heard of congenital *craniotabes*, and doubtless you have seen well marked examples of it at your clinics. This condition you know means an imperfect extension of the centres of ossification in the parietal and occipital bones, a want of the deposit of bony matter, as a result the cranial covering in places is like a mere membranous cap, jotted here and there only with islands of ossification. Of course a condition of this kind will not protect the delicate brain centres from external pressure and trismus will result.

It has been a question much discussed whether or not this condition is an unmistakable or invariable evidence of congenital syphilis, as some authorities claim, but I think that our experience warrants the statement that inherited syphilis, being also a disease of the general nutritive process, can by simply retarding development be in itself a cause of this form of rickets, and that independent of it, the rickety diathesis alone, when acquired in utero will act as an equally potent cause. I might even go further and state that the tubercular and scrofulous diathesis of ante-natal acquisition would give us the same result.

I have seen babes born of syphilitic mothers with *craniotabes* and I have also seen *craniotabes* in new born children, where no specific history could be found; a marked example of this oc-

curred during my term in this Hospital two years ago; one of a pair of colored twins died shortly after birth, of convulsions, and its skull presented the picture that I have just drawn for you. The other child lived and gave us an example of marked rickets, and if my memory serves me right, died of catarrhal pneumonia, a frequent complication of the rickety thorax. As to the cause of rickets independent of hereditary predisposition, the following present themselves as powerful determining influences; insufficient or improper food, faulty assimilation, residence in dark, damp, ill-ventilated places, exhausting diseases; all of these play their part, with the addition of that ever important state, the what is it of etiology, a tendency to the production of disease.

Various theories have been promulgated as to the production of rickets: one a deficiency of phosphates in the blood; the other an excess of acids, mainly lactic, which dissolve the phosphates, and thus allow them to be eliminated by the kidneys, instead of being deposited as alkaline lime salts in the bones; in other words, the osseous metamorphosis does not occur, the diploë of the flat bones enlarge, and the laminae separate more or less from each other, forming interlamellæ, which finally fill up with gelatiniform fluid.

The consequence is that as the bone becomes curved, the periosteum relaxes on the concave side, and the deposit at that part becomes excessive.

There is increased vascularity of all the constituents of the bone; we find the periosteal, medullary, cortical, and cancellated structures congested, deeply reddened, and filled with this gelatinous transudation.

Gradually the laminae become thinner and more yielding, the bone becomes greater in its porosity, and when the new material is washed out, the weight of the bone is found to be less. Rokitsansky tells us that if we boil the rickety bones, the result is unlike the chondrin or other animal matter of sound bony tissue.

The diaphyses and epiphyses of the long bones are separated by an increased mass of uniting cartilage, the ligaments become lengthened and relaxed, presenting the appearance designated "*articuli duplicati*," or double jointed: the bones most in use are earliest deformed.

The rachitic skull is generally described as square: it is usually flattened in all directions; the sutures late in closing are usually depressed; the thorax develops a lateral depression between the third and ninth ribs, owing to the action of the scapular and humeral muscles, together with the force of atmospheric pressure. The sternum is forced forward and becomes prominent at or below the ninth rib.

The pelvis may also be greatly deformed; its upper portion may be expanded and the lower contracted; thus, in after life, seriously affecting the mechanism of labor, as we frequently see in our lying-in wards.

The teeth of rickety children are retarded: in practice, if the child does not present a tooth at twelve months, we generally regard it as pointing to a rickety diathesis; you will also usually find the fontanelles patent, especially the anterior, which will remain so until the twentieth month,

or even later. There is liability to perspiration about the neck and head—Jenner tells us that this is diagnostic of the disease; the urine is increased in amount; the bowels are variable, alternating between a condition of constipation and one of diarrhoea; hyperæsthesia is sometimes a marked symptom. The lungs may be attacked by pneumonic, catarrhal or tubercular phthisis; the brain may be œdematous, or its ventricles may be filled with serum.

The bronchial and mesenteric glands are enlarged; the intestinal glands are also involved in the general dyscrasia; hence, we have as a prominent symptom, disordered nutrition, together with the consequent emaciation, wasting of the muscles, and loss of color.

The osteomalacia or malacosteon affecting women after child-birth, of which we see a number of examples in this house, bears a close relationship to the rickets of children; but the former is confined to adult life, while the latter is a disease peculiar to children. Malacosteon is also attended with severe pains.

Parents are always solicitous as to the *prognosis* of rickets. The result is the same as I have told you in all the diathetic diseases, if the inherited taint is not too overwhelming, our little patients will eventually practically recover, although the deformities of the disease still remain. This is especially so when the disease commences about the second year or later, and only affects two or three bones.

You must pay due regard to the condition of the gastro-intestinal tract as an important factor in making up your prognosis.

Unfortunately, in the major portion of your cases, you will not find the disease pursuing so favorable a course, and the little sufferer will perish either from exhaustion, bronchial or intestinal catarrh, or occasionally by an exanthemata as a complication.

In the *treatment* of these cases, your first thought should be as to their hygienic condition and surroundings; and see to it that these are as perfect as circumstances will permit.

Food next calls our attention. If the child is still nursing, experience will tell you that there is no food so well adapted to its use as the maternal milk, provided, of course, that the supply is sufficient and of proper quality, and that the mother is not a victim of any of the four diatheses about which I have told you so much during our visits to the wards. As the child grows older, its diet must still be uppermost in your plan of treatment.

We have no medicinal agent which acts as a specific in this disease (as you know iodine and mercury do in the syphilitic diatheses), but we must exhibit our drugs in order to meet special indications. Lime water meets the condition of the gastro-intestinal tract, and also supplies the bones with the needed material. A good plan is to give it with the milk. Cod-liver oil should be our sheet anchor to prevent emaciation. Give it either internally or by inunctions; the latter method you will find acts marvelously in these cases.

Iron, as the tinct. of the chloride, must also be supplied as an hæmatic, and for its restraining property on the bowels.

Salt sea baths, among the rich, are good adjuncts to your general treatment.

Let us devote the balance of our time this afternoon to a study of some of the diseases of early infancy and their treatment, using as our text the abundant material which you see the wards present.

We will begin by studying *ophthalmia* and its forms, the *blennorrhœal* and the *catarrhal*.

This disease is more prevalent in asylums, and a glance around the ward will convince you that our hospital is not an exception to the rule. Want of cleanliness or *dirt* is a factor in its production; it occurs at times with puerperal fever; leucorrhœa or gonorrhœa in the mother may produce ophthalmia in the child; when produced by the latter it is perhaps the worst form of inflammation of the eye that you will be called upon to treat.

This little patient, who is suffering from simple catarrhal ophthalmia, illustrates well the disease as you will usually meet it. Note the bloodshot appearance of the eyes with soreness and pain; you notice that it turns its head as much as possible from the light. In the right eye, which is the most affected, you will please notice this irregular injection of the conjunctiva, which, unfortunately for the patient, is becoming general and velvet-like, with here and there a raising of the mucous membrane in spots like water blisters; this we technically designate *chemosis*. There is a mucous discharge which agglutinates the edges of the eyelids; this is more noticeable at night or upon arising. This is about the extent to which the catarrhal variety reaches, but not so in the blennorrhœal or purulent form; here the course is rapid, twenty-four to thirty-six hours.

This little lad presents us a typical case: here we perceive much swelling, the conjunctiva has assumed a deep red hue; you also note numerous fine granulations, occasionally flakes of pseudo-membrane; abundant creamy pus, at times tinged with blood, is poured out.

This is a very critical period, the dangers lying in the fact of the possibility of rapidly destructive ulceration of the cornea causing blindness, although it is possible for a considerable ulcer of the cornea to heal in a child, even without leaving an opaque cicatrix.

The treatment must be prompt and vigorous; the pus must frequently be removed by injections of warm water, which may be carbolated, or Smith recommends a solution of corrosive sublimate. We may use alum, grs. iij. to ℥j.; Von Graeff uses a strong solution of argenti nitras. As very much depends upon the vital energy of the child's system, pay especial care as to its nourishment, bathing, and the state of its bowels.

The catarrhal variety, of course, does not require such active treatment.

It is well to start out by the administration of a saline cathartic. Here you may use a mild wash of nitrate of silver, one or two grains to the ounce, or some of the other mild astringent washes. If the disease remains rebellious, leeches back of the ear, or a blister applied to the temple, will materially aid in the cure. It is just as important here as in the severer forms of the disease, to keep the eyes clean; and I may add that great care should always be exercised in washing the eyes of the

new-born. As the subjects of these diseases are generally more or less cachectic, you will find it advantageous to place them on a general tonic treatment. The 25% to 50% emulsions of cod-liver oil, containing a certain proportion of the phosphate of iron dissolved in them, say one to two grains to teaspoonful, are valuable.

Then again, you will find, as I have so often told you, hygiene and a well-regulated diet to be your sheet anchor.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Pleuro-Pneumonia.

The patient was a robust, strong-looking young man, with dark complexion. He was admitted to the hospital October 31. Age 24. Unmarried. A reporter. Drinks occasionally. Family history is negative. He gives no personal history. He has always been well until the 23d of October. He then felt sudden, sharp, darting pains in his right side, which extended to the lower part of the chest, and down toward the groin, and they were worse on coughing. He had not been unusually exposed to cold or wet before this, and knows no cause for it. He soon became feverish, and was obliged to take to his bed. He was treated by a physician outside of the hospital, and was relieved by the application of a fly blister. He has had no chill, and no urinary symptoms. Is suffering from anorexia. At the time of his admission his pulse was 120 per minute, respiration 40, temperature 104.8°, at twelve o'clock 103°; November 2, morning, temperature 102°, and evening 103°; November 3, morning, 103°, and now, at 4 p. m., it is 103.2°.

You observe, gentlemen, that the range of temperature has been pretty high since he came in and has been under observation, and it was probably high before and ever since the beginning. The high temperature at the time of his admission was probably due to disturbances caused by his removal to the hospital. It is a rule here to find a higher degree of temperature at the time of entrance than prevails on the following day; for the excitement of being moved, and the change, cause a temporary increase of the fever. So it was in the case of this man.

You notice that the expectoration is rusty in color, and this is due to the coloring matter of the blood; but it is not so viscid as we usually find it in pneumonia. It is more like what we get in bronchitis, but we usually have some bronchitis with pneumonia. I will now make the physical examination to see what more we can learn.

Auscultation.—On listening over the back of the chest, I find that he breathes with tolerable freedom, and the movement is almost symmetrical on both sides, or perhaps a little freer on the left. The vocal fremitus is more marked on the left than on the right.

Percussion.—When I percuss over the back of the chest from above downward, you observe that as I pass below the spine of the scapula on the right side, the percussion note becomes duller, and as I get a little lower it becomes absolutely dull. On the left side there is fair resonance, and

percussion with the flat of the hand makes the difference on the two sides more evident than does mediate percussion. In front, on the right side, dullness begins at about the same level as behind; but the line of dullness is altered by change of position, showing that there is fluid in the pleural cavity. But this is not an uncommon complication with pneumonia.

On auscultating again below the line of dullness on the right side, I find an absence of the respiratory murmur, and even during the forcible inspirations produced by coughing no air is heard to enter the lungs below this line. When auscultating and the respiratory sounds seem to be absent, it is important to ask the patient to cough, especially if it be a very feeble person, as this is often the only way by which you can introduce air into an apparently impervious lung. Sometimes the breathing is so extremely shallow that full inspirations are not taken, and the air does not seem to enter certain parts of the lungs, but the act of coughing shows that it does enter. While the vocal resonance in the upper part of the chest on the right side is normal, as we approach the line of percussion dullness we here get the peculiar sound known as *œgophony* or a bleating bronchophony which indicates the presence of fluid.

Now, in this case, from the subjective symptoms and the objective examination, why would you suspect that there was something more here than simple pneumonia? It is because the fever chart shows that there has been no crisis, and the fever continues high although this is the twelfth day, while in pneumonia we get the crisis between the fifth and the eleventh day. One more important point remains to be determined here, and that is whether the fluid in the pleural cavity is serous or purulent. We can not infer positively that it is purulent because of the continued fever with its periodical exacerbations. But this question can be determined at once by introducing a needle and examining the fluid drawn off. This will be done here, and you will learn the result at the next meeting.

MEDICAL SOCIETIES.

PROCEEDINGS OF "THE COLLEGE OF PHYSICIANS OF PHILADELPHIA."

The History of a Case of Abdominal Cystic Tumor, where Seven Years after Removal of the Tumor by Laparotomy a Second Operation was Demanded: Tapping through the Vagina Resorted to, with Consequent Death of the Patient.

BY WALTER F. ATLEE, M. D.

[Read March 7, 1883.]

Bene facit qui ex erroribus suis exemplum aliis præbet.

In June, 1875, I removed, by laparotomy, in the St. Luke Hospital, Bethlehem, a multilocular cyst from Mrs. DeM—. The history of the case was given by Dr. Stout to the Board of Trustees, and published in their second Annual Report. The whole mass removed at the operation weighed seventy-eight and a half pounds. The lobes and

lobules composing it were made up of cysts containing fluids of different densities, colors, and other physical properties. The pedicle appeared to arise from the rectum; at all events, the cyst wall was separated from everything else, except the front of that intestine, and the only ligature used was there applied. The whole vascular supply was derived from meso-rectal vessels. Of course, the clamp could not be used. As always, in sewing up the incision in the abdominal walls, I carefully included the peritoneum in the sutures, as in this way adhesions of intestine and omentum, with the consequent discomfort and constipation suffered by the patient, are never observed, and, moreover, in case a second ovariectomy should have to be performed, the operation could be performed with much more ease and safety.

This patient recovered from the operation; though somewhat slowly, owing to delay and difficulty in removing the ligature, which was left hanging out of the external wound, and not cut short and left inside the abdomen, as is now generally practiced. She remained in perfect health for seven years, but in the summer of 1882 came to my office complaining of considerable discomfort in the pelvis, where I detected, by the touch, the presence of a swelling, caused by a thick, viscid fluid; in other words, there was plainly a second tumor formed there. This continued to enlarge, and in the month of January the suffering it occasioned was so immediately threatening to the patient's life, that it was necessary to act. Great efforts were made to push the tumor out of the pelvis, but this was not to be accomplished. It remained to operate as before, and remove the mass by laparotomy, or to give relief by emptying the cyst by tapping through the vagina. The latter procedure was preferred, and about three pints of a very thick, dark-colored fluid were drawn off by a Thompson trocar. There was no difficulty about the operation, nor was it attended by any particular pain, nor was there any hemorrhage. The next day the patient felt herself completely relieved, but after that her pulse became quickened, and a general febrile condition, unpreceded by chill, succeeded. There was evident tenderness on pressure over the lower part of the abdomen, but no severe pain independent of this pressure. The stomach became so irritable as to reject everything swallowed. Death took place on the eighth day, under the marked symptoms of depression which accompany pyæmia. It was a death, most plainly, from cyst inflammation.

Notwithstanding the great number of cases of operation for ovarian disease reported nowadays in journals, more or less medical, this case is really one deserving of record, and one of true and special interest to the pathologist and to the surgeon.

In removing the large mass in the first operation, in this case, it was noticed that no pedicle was found. It was separable by the fingers everywhere except from the front of the rectum, where it was necessary to apply a ligature and divide the attachment by scissors. The ovaries, as we all know, are situated in the posterior fold of the broad ligaments, on the sides of the highest part of the uterus, behind the Fallopian tubes, and the round ligaments which separate them from the bladder, and in front of the rectum, from

which they are commonly separated by the lowest circumvolutions of the ilium. By a rounded cord, the ligament of the ovary, they are attached internally to the womb, and externally by two folds of the peritoneum to the sides of the pelvis.

As the ovary, in its normal condition, is not pediculated, at first, of course, a diseased ovary has no true pedicle. As it becomes larger, this pedicle is formed from changes in its normal connections with the adjacent womb; it consists of the Fallopian tube often much elongated, the broad ligament often considerably thickened, the utero-ovarian ligament occasionally hypertrophied to a large fibroid stem, the round ligament, and enlarged blood-vessels. If the tumor rises out of the pelvis, the pedicle will be longer, and if bound down in the pelvis from early adhesions it will be shorter.

In some cases, however, and they are by no means rare ones, when cystic tumors are removed from the abdominal cavity, no such pedicle as the one just described is met with. In the case, whose history I have been relating, it was said that there was no distinct pedicle, and that the whole vascular supply came from the vessels of the meso-rectum. It may naturally be supposed that this was owing to the way in which the diseased mass may have been separated from its surroundings, and I therefore call attention to the fact that the same thing has occurred in the practice of an operator such as Spencer Wells. In his *Diseases of the Ovaries*, in relating Case CX., he says that he found no pedicle, and that the tumor derived its vascular supply from the omental and mesenteric vessels.

It seems to me most reasonable to look upon some of the abdominal tumors having these connections, not as enlarged and diseased ovaries, but as changed ovules, which have failed to enter the Fallopian tubes, have slipped into the interstices of the neighboring organs, become attached, received blood, and grown. In women, when the Fallopian tube has become adherent, in place of floating loosely, the ovule is not grasped as it leaves the ovary, and then it is not rare to see ten, fifteen, twenty, or even more small cysts, some as large as a pea, on the parts immediately in contact with the ovary. (See Sappey, vol. iii., p. 644.)

If one of these misplaced ovules was attached to a spot, where plenty of blood was supplied, a large cyst could be formed, having no distinct pedicle, as in the case before us. As is seen in cases of extra-uterine foetation, a well-made child can be formed in this way from a fecundated ovule, and we may suppose that from an unfecundated one a monstrous polycystic growth should form.

Although out of the way, I wish to mention here that the only two cases in which I have been consulted on account of a return of abdominal cystic tumors, were where there was no pedicle, and where the chief vascular supply came from the vessels in front of the rectum. One case is the one now under consideration, and the other is the one published in the *American Journal of Medical Sciences* for January, 1883, on account of the bladder having been opened during the operation.

My reason for reporting this case, however, is not to advance any particular views in regard to

the pathology of certain polycystic tumors of the abdominal cavity, but in order to speak of the mistake made in the treatment. In the words of one who has done as much as any other to advance our knowledge of the treatment of abdominal tumors: "Mistakes teach most valuable lessons, and, when discovered, are not likely to be repeated. Hence, in medicine, they should be recorded for the benefit of science and of humanity." (*General and Differential Diagnosis of Ovarian Tumors*, by Washington L. Atlee, in Preface.) When this case presented itself, it was necessary to act; a speedy and most painful death was inevitable, unless relief were afforded. It remained to choose between the removal of the cyst and the emptying of its contents by tapping through the vagina, the only way practicable of introducing a trocar. On account of the operation previously performed, and the impossibility of moving the mass in the pelvis; its removal was not attempted. A previous operation is not necessarily an objection; Dr. Washington L. Atlee records two cases where a second operation was performed, and in both successfully. Spencer Wells, in his table, gives thirteen cases in which he removed an abdominal tumor from a patient who had previously undergone the operation, and eleven of them were successful. Here, however, the immovability of the tumor was such as to make me positively sure that the attachments were so great as to render its removal impossible.

Of tapping through the vagina I had no personal experience whatever, and what is recorded by others, although not, as a general rule, favorable to the plan, did not deter me from it. Scanzoni goes so far as to say that if puncture by the vagina was always possible, abdominal puncture would soon completely disappear from surgical practice. The sac, opened in its lowest part, can empty itself more completely. (Scanzoni, *Traité pratique des Maladies des Organes sexuels de la Femme*, Paris, 1858.) Peaslee says that there are three considerations to deter us from it in all ordinary circumstances: 1. The vessels are larger and more numerous at the lowest part of the tumor. 2. If polycystic, the largest cysts are not at its lowest part. 3. There is greater risk of wounding other organs. (Peaslee, *Ovarian Tumors, their Pathology, Diagnosis, and Treatment, especially by Ovariotomy*, 1872.)

Emmet writes that he has punctured several cysts with a trocar from the vagina, and in every instance more or less cellulitis has resulted. This might, however, destroy the cysts, but he is not able to determine that, for all the cases passed from under his observation. (Emmet, *Principles and Practice of Gynecology*, 1880.)

Thomas says that by this method two of the dangers of tapping, secondary escape of fluid into the peritoneum, and consequent peritonitis, are unquestionably avoided, but others are as surely increased, namely, those of injury to portions of the intestine and entrance of air into the sac, with consequent decomposition of the contents, septicæmia, and inflammation of the sac walls. His experience with the method is not large, but it leads him to agree with Spencer Wells. (Thomas, *Diseases of Women*, 1872.)

Spencer Wells says that tapping through the vagina is more liable to be followed by inflamma-

tion of the cyst than tapping through the abdominal wall, because it is not easy to prevent the entrance of air. The operation of tapping through the vagina is selected, not so much with the intention of simply emptying the cyst, as for the chance that should the fluid escape by the opening, as fast as it is secreted, the cyst may gradually contract, and the puncture close. This favorable result, however, is seldom secured. As a rule, air enters the cyst, the opening fills up, the fluid remaining in the cyst, or that newly secreted putrifies. Suppurative inflammation of the lining membrane of the cyst comes on, and is accompanied by a low form of septic fever or pyæmia, which can only be relieved by making and maintaining a free outlet for the discharge. The frequency of these consequences should make tapping by the vagina an exceptional practice, but it may be adopted in cases where an ovarian cyst is bound down in the pelvis by adhesions, and it is necessary to relieve the distress caused by pressure on the bladder and rectum.

The canula or an elastic catheter may be left in the cyst, though it is safer practice either to introduce a wire seton or a drainage tube, so as to prevent the opening from closing, and make sure of the free and immediate escape of any fluid that may be secreted. Even with every care, however, Mr. Wells concludes, from his experience, that patients are so apt to suffer from some of the ill effects of long-continued suppurative processes, that it is better, even at considerable risk, to remove a cyst, if at all possible, than to trust to any mode of drainage. (Spencer Wells, *On Ovarian and Uterine Tumors, their Diagnosis and Treatment*, 1882.)

Dr. Charles West, whose opinions have for me, at least, extraordinary importance, greater indeed on such a point than those of any other man, says that there is no doubt but that inflammation attacking parts within the pelvic cavity is less apt to extend to the peritoneum than when it attacks an abdominal organ; of which rule pelvic cellulitis and inflammation of parts within the folds of the broad ligaments are apt illustrations. It is equally incontestable that pelvic peritonitis is less apt to become generalized than is similar mischief originating in the abdomen. Cyst inflammation is so dangerous, however, that it is doubtful if vaginal tapping may be employed, even when the cyst is simple. Its dangers are incalculable. The dangers of ovariectomy are far less. Except when a cyst is impacted in the pelvic cavity, he does not recommend tapping per vaginam. (West, *Lectures on Diseases of Women*, 1879.)

Our best authorities, therefore, teach us that the tapping of polycystic tumors at least must be avoided; that the removal of the cyst is to be practiced in preference; that when impacted in the pelvis, so that it interferes with the performance of functions absolutely necessary to life, tapping, to which we must have recourse, is particularly dangerous, owing to the frequency of cystic inflammation, and consequent death from septicæmia. In my case I thought to avoid this by taking precautions to hinder the entrance of air into the cyst, but it took place notwithstanding, and the death of the patient was occasioned by it in eight days.

If, unhappily, I should ever again be called upon to try to relieve a similar case, I should act differently, and, not relying upon any means to prevent the setting up of cystic inflammation, do more to establish a free outlet for the noxious products by which the system is poisoned, and do everything in my power to prevent their formation by topical applications to the secreting surfaces of the cyst.

Dr. Noeggerath (*Ovariocentesis Vaginalis*, *American Journal of Obstetrics*, May, 1869), by pursuing this course, had such good results as to declare himself confident that, where a simple or compound cyst could be attacked through the posterior vaginal cul-de-sac, this operation would take the place of laparotomy. The plan he prefers is to make first a transverse incision, about an inch long, behind the cervix uteri and through the roof of the vagina up to the cyst. This, coming into view, is then evacuated by a free incision, and, finally, the edges of the two incisions are stitched together by five or six silver sutures. The cyst thus left free and permanently open is daily washed out with antiseptic injections until it finally contracts, and ceases to afford any secretion. Although, at the present time, it is not likely that in ordinary cases any one would choose to perform this operation to that of the removal of the cyst, yet all experience shows that when the cyst is so firmly fixed in the pelvis as not to be removable, it diminishes in a marked degree the great danger necessarily incurred by tapping through the vagina—that of poisoning of the system by the absorption of the putrid products of cystic inflammation.

I feel certain myself that I made a sad mistake in not operating in this way, and report this case as a warning to others—*Bene facit qui ex erroribus aliorum, sibi exemplum sumat.*

[After the reading of the preceding paper:—]

Dr. William Goodell said that he did not think the attachment of the tumor to the rectum was so unique as the return of the tumor. He had on several occasions removed tumors without being able to find the true pedicle, on account of the many adhesions. He could not agree with Dr. Atlee with regard to the origin of the cyst—he did not think it could have come from a wandering ovum, since, in that case, it would have been monocystic.

He regarded tapping per vaginam hazardous, for the reasons given by the late Dr. Peaslee, first, on account of the danger of wounding blood-vessels, and second, on account of the danger arising from the entrance of air into the cyst. He did not understand why the air could enter the cyst so readily after tapping per vaginam. When he performed tapping by this method he employed the aspirator. Returning to the question of the attachment apparently of the pedicle to the rectum, in the case reported, he said that it was quite common not to find a pedicle in some forms of intra-ligamentous cyst, because they had to be enucleated, and referred to the statements of Lawson Tait with regard to this difficulty of determining the origin of the tumor. He desired to call attention to the pathological characters of the recurrent growths, and stated that according to his observation they were always malignant, and that they recur in the stump of the pedicle, or, as he

had seen, at the site of the adhesions. He alluded to a case which occurred in his own practice, and to one related to him by Dr. Bantock, of London, which confirmed the statements made.

He asked Dr. Atlee whether he could explain why the air entered so readily into cysts after tapping per vaginam.

Dr. Atlee, in reply, said that he had seen no reason given, but thought it was owing to the difficulty in closing the wound made in the tapping.

Dr. R. P. Harris remarked that perhaps he could throw some light upon the cause of this admission of air, from what he had observed in a case of removal of hemorrhoids. Some years ago, soon after the introduction of the *écraseur* of Chassaignac, he called in the late Dr. Joseph Pancoast, who had obtained the instrument, to make use of it in removing a mass of hemorrhoids from the rectum of a very anæmic man, rendered such by repeated hemorrhages after defecation. After the operation, to prevent, as he stated, the suction power of the diaphragm upon the rectum, endangering secondary hemorrhage, Dr. Pancoast introduced into the anus a small box-wood tube. The effect of this was soon demonstrated: a large drop of serous fluid descended the tube and stopped at its exit; when the diaphragm arose in expiration, the drop was drawn up the tube, and when it descended in inspiration, it came down again; thus showing the pumping effect of the diaphragm upon the pelvic contents. Let this open tube become an opened cyst with flaccid walls, and we have air pumped into the cyst, as it was into the rectum of our patient.

Dr. J. Ewing Mears asked Dr. Atlee whether a post-mortem examination had been made. He thought the observations of Dr. Goodell with regard to the difficulty of finding the true pedicle in tumors with many adhesions, and to the pathological characters of the recurring tumor in these cases, to be correct, as such had been his experience in instances of which he had had personal knowledge. With regard to the entrance of air into the cyst, when tapping is performed per vaginam, he thought the explanations of Drs. Atlee and Harris were correct. A cyst firmly impacted in the pelvic cavity is separated from the vaginal tube by a comparatively thin septum, differing greatly in its anatomical characters from the abdominal wall. The opening made by the trocar in this septum and in the cyst wall attached to it by adhesions, does not close perfectly, and the air drawn up into the vaginal tube passes readily into the collapsed cyst.

Dr. Atlee, in reply to Dr. Mears, stated that no post-mortem examination had been made.

Consumption of Tobacco.

According to *Les Mondes*, it appears that in Russia, France, and England, the consumption amounts to one pound per inhabitant. In Italy it is rather higher, one and a half pounds. Austria comes next with two and two-fifths pounds. In the United States and Germany the consumption amounts to three pounds, in Belgium to four and four-fifths pounds, while Holland has the privilege of heading the list with a consumption per inhabitant of more than five and a half pounds.

EDITORIAL DEPARTMENT.

PERISCOPE.

Certain Proof of the So-Called Uterine Milk in Man.

The *Edinburgh Medical Journal*, February, 1883, says: Under this title G. Von Hoffmann contributes an interesting article to the subject of placental physiology to the *Zeitschrift für Geburtshülfe und Gynäkologie*, Bd. viii. Heft 2, S. 258. The author supports the views of those who, like Ercolani, maintain that even in the human species the placental villi do not project freely into blood-spaces in the maternal part of the placenta, but are always covered with the milk-secreting organ, which is developed in the upper layers of the serotinal decidua during pregnancy. The sinus system, as it is called in the human subject, is, according to our author, made up of this milk-secreting organ. But in consequence of the dilatation of its walls in the course of development, some maternal capillaries become thinned and burst, so that permanent lacunæ are formed, through which maternal blood enters the sinus and mixes with the uterine milk secreted from its walls, which are, of course, made up of altered decidual surface. This maternal blood and uterine milk is absorbed by the fetal villus for the nourishment of the fetus. The method adopted by the author to prove his theme is not so much an anatomical as a physiological one. He provided himself with fine capillary lymph-tubes. Then, laying the fresh placenta flat, with the maternal aspect upwards, and wiping its surface very carefully with a sponge, he introduced these tubes, some obliquely, some perpendicularly, to a distance of from 1 to 1½ centimetre. The intention was that these tubes should penetrate the placental tissue so as to pass between the foetal villi and pierce the intervillar spaces, extracting from the latter part of their contents by capillary attraction. In this way the author made observations on forty fresh placentæ obtained at the end of pregnancy, and on those obtained from many abortions at various months. He found the fluid thus obtained consisted of—1. Red blood-corpuscles of various sizes and forms. 2. Colorless blood-corpuscles, somewhat larger than usual, but not in large quantity, being only about 1 or 2 white in 100 or 200 red corpuscles. 3. Uterine milk-cells. These occupied by far the greatest amount of space, and his view of their nature he supports by comparison with the fluid found in the cow's placenta. 4. Free intercellular fluid, clear as water. Less constant constituents of this fluid were—5. Decidual cells, floating freely, with nuclei and nucleoli. 6. Small round bodies, probably derived from red blood-corpuscles. 7. Small particles, or detritus, often colored red. 8. High-colored pigment-cells. 9. Certain irregularly formed azure-blue bodies. The fluid obtained in this way, on being collected in quantity and allowed to stand in a small test-tube, separated constantly into two layers, the upper layer

being invariably formed of the uterine milk mixed with blood-serum, the lower consisting essentially of red blood-corpuscles. The author compares the fluid thus obtained from the human placenta with that obtained from the cow's placenta, and finds that the elements he ascribes to the uterine milk are essentially the same in both, but that in the human placenta a considerable amount of blood is mixed with the milk, whereas in the cow scarcely any blood-cells are found. The author's results are finally formulated by him in the following propositions: 1. The destiny of the decidua in general in animals, as well as also specially in man, is that of affording to the fetus, during its intra-uterine life, a portion of the nourishment necessary to its growth. For the fulfilment of this task the serotina or decidua placentalis is transformed into a special milk-secreting organ, which is thrown off after delivery along with the placenta as an integral portion thereof. 2. The secretion of this organ, the so-called uterine milk, is secreted into the gradually-formed spaces in which the placental villi are situated. Here the uterine milk is commingled with the contemporaneously extravasated maternal blood, and, taken along with the latter, represents the foetal nourishment which only now appears suited for being absorbed by the foetal villi. 3. From the standpoint of comparative anatomy, the view of an essential difference between the placenta of the higher orders of animals and man is no longer tenable in the sense hitherto accepted, according to which an entirely separate position has been assigned to the human placenta in the scale of development. The author postpones for a future work the consideration of how the absorption of the foetal nourishment by the villi takes place, as well as other matters therewith connected.

Carbolic Acid Injections in Hydrocele, Ranula, and Cystic Tumors.

Dr. P. E. Sandidge thus writes in the *American Practitioner*, February, 1883: The purpose of the present paper is to give an account of a few cases of hydrocele, ranula, and analogous tumors, which I have treated in the last dozen years by injections of carbolic acid.

In March, 1868, I saw Mr. W. with my late lamented friend, Dr. J. W. Beauchamp, sr. The case was one of double hydrocele. Being led to think of carbolic acid as a probable cure for hydrocele by reason of what I had witnessed of its effects, in the year or two preceding, in promoting the healing of wounds, I suggested its use as an injection in this case instead of the tincture of iodine, or port wine, etc.; but, Dr. B. objecting, I emptied the sacs and threw in the tincture of iodine after the usual manner. The patient did well, and the operation seemed to be a success.

Two years later the vaginal tunic again began to distend, and in April, 1871, I was called to operate a second time. The tunic of the right side was greatly distended with a dark-looking

fluid, which I drew off with an ordinary trocar and canula, and injected two or three drachms of a solution of Calvert's carbolic acid No. 5, one part of water to three of acid. I manipulated the walls of the sac in such a manner as to bring the solution in contact with their every part, and then slowly pressed it out. The contents of the left tunic were clear. Having withdrawn them through the canula, I threw in two drachms of tincture of iodine, kneaded the parts, and withdrew the injection as on the right side. Two hours later the patient suffered intense pain and heat, with retraction of the testicle of the right side. The scrotum was much swollen and red, and the penis became erect. Rigors soon followed, and these in turn were followed by fever. The left side underwent no change. A brisk purge or two, rest in bed, low diet, and cold lotions to the inflamed parts, straightened matters, and in ten days the case was dismissed. The right testicle remained for a time somewhat retracted, and the scrotum on that side considerably corrugated. There were no marks of trouble on the left side.

Nine months after (January, 1872), the left tunic had refilled. The right was cured. I emptied the sac, injected carbolic acid solution, and got a speedy cure. The patient, now alive, has never had the slightest return of his complaint.

Mr. H., a farmer, thirty-five years old, who had a hydrocele succeeding upon an attack of abscess of the epididymis, was cured by a single injection of carbolic acid. The patient died six years after with consumption, without having had a return of his hydrocele.

From April, 1871, I have treated a considerable number of cases of hydrocele by the simple method here mentioned, with uniform success. I have not had to use the injection more than once in a single case. It has also come in my way to relieve a number of subcutaneous cystic tumors by the same means. I have had equal success with carbolic-acid injections in the treatment of ranula. The following report of a case may be interesting:

In November, 1876, I saw, with a medical friend, a girl thirteen years old, otherwise in good health, having the largest ranula I had ever met with. It positively hung under her chin like the pouch of a pelican. It pressed the tongue up against the roof of the mouth, interfering with articulation, deglutition, and respiration. Here, as in the first case of hydrocele I mentioned, I yielded to the wishes of my medical friend, and operated in the usual way, using tincture of iodine as the irritant. The following April the sac was more distended than ever before. I at once withdrew the fluid through a canula introduced at the most dependent portion of the tumor, and injected six ounces of Calvert's solution of carbolic acid No. 7, and took care to bring it in contact with every part of the cyst before it was withdrawn. The parts quickly became red and intensely painful. Rest in bed was enjoined, cold applications with moderate pressure were made to the parts, and a saline purgative given. Nothing further untoward occurred, and the sac has never refilled.

I have treated two cases of ranula since that time by the same method, with like success.

Adherent Placenta, Retained for Years, Simulating Cancer.

Dr. George F. French, of Minneapolis, Minn., reports the following case in the *Northwestern Lancet*, March 15, 1883:

Mrs. A., æt. 42, mother of twelve children, has always had profuse menstruation. Four years ago had twins; the placenta was adherent, and had to be detached by force. The attending physician thinks he must have left a considerable portion of it. Since that time the menorrhagia has increased. Two years ago the patient was delivered of her last child, since which time there has been a more or less constant flow or dribble. For two months it has at times been alarming, and on several cases the attending physician found it necessary to tampon. The patient came under my care the 1st of December. I found her blanched from loss of blood, swallow, and very weak. She could not assume the upright position without fainting. Mingled with the blood which was escaping from the uterine cavity, there was much watery and foul-smelling purulent discharge.

Digito-vaginal examination threw no light on the case. No tumor was to be felt; the uterus was neither enlarged nor fixed, but the os so patulous that dilatation was unnecessary. I had hoped to find myself dealing with merely a granular degeneration of the mucous membrane, but the foulness of the discharge and the exhausted state of the patient made me apprehend grounds for the existence of some cancerous affection as the attending physician had intimated. On the other hand, the complete absence of pain, and the mobility of the uterus, as well as its small size, were grounds for hopefulness. On exploring the uterine cavity, I at once eliminated the possibility of any pedunculated tumor being present, and in order to arrest the hemorrhage, which was still unabated, and to throw greater light on the further diagnosis of the case, I scraped over the surface of the entire uterine cavity with a Sims' curette. The instrument did not meet with the usual resistance common to cases of granular polypoid degeneration (in such cases you can both feel and hear the resistance offered by the underlying muscular surface), but I brought away a pulpy substance, which, under the microscope, Dr. Hunter discovered to be *placental tissue*. The operation was followed by a severe chill, and the temperature on the next day was 104°. This disturbance of the system, however, was very brief, and in forty-eight hours had entirely disappeared. There has not been the slightest return of hemorrhage, and no pain attended or followed the operation. The patient eats and sleeps well, and there is no longer any doubt of a speedy and complete recovery.

Stenosis of the Trachea and Bronchial Tubes, with Amyloid Change in their Walls.

Dr. W. Balser* contributes an article with the above title. The case occurred in 1877. Nineteen years previously, the patient, then 45 years of age, consulted his physician, who found considerable consolidation in the upper lobe of the right lung, especially anteriorly. One year later

* Virchow's Archiv., Bd. xci., H. 1.

a severe bronchitis manifested itself, and five years later asthmatic trouble. In the latter years of life, the signs of bronchial stenosis appeared, which, in the last half year of life, reached their maximum, but never was there any abrupt change for the worse noted. The voice was not much affected except in the latter years, and complete hoarseness was never present. The chronic pneumonic process, together with an increase in the stenosis, accompanied by general emaciation and anæmia, progressed until death. At the post-mortem examination, the mitral and aortic valves were found diseased, and there were atheromatous changes in the aorta, but the chief interest attends the pulmonary organs. The larynx was strongly ossified, the trachea and bronchi formed stiff, scarcely flexible tubes, and their mucous membrane was greatly congested, and covered with gray-red mucus. Besides the extraordinary rigidity of the trachea and its ramifications, the trachea was compressed flat from side to side. The tracheal wall was very thick, and nowhere was the mucous membrane of it or the bronchi in a normal condition. In its superficial layers it was puffy, pitted, and granulated, in reality composed of several components, partly whitish or bluish cicatricial tissue, partly copious yellowish-red gelatinous masses, and some reddish, and in places dark-red colloid granulations. At the same time there appeared in the mucous membrane, especially in the lower parts of the bronchial tubes, numerous small bony rings. At the bifurcation of the trachea, the calibre of the bronchi was so narrowed as to scarcely permit the entrance of the tip of a little finger. The lungs were large and emphysematous. Numerous patches of induration were visible, and evidences of peribronchitis. A very thorough microscopic examination of parts of the trachea and bronchi revealed extensive amyloid changes, sections without previous hardening being possible on account of the extensive calcification of the walls. He believes that either with or after a chronic bronchitis with consolidation, an echondrosis trachealis multiplex developed, and upon the first the amyloid and other changes in the trachea were dependent.

Rare Sequelæ of Enteric Fever.

From the *Medical Times and Gazette*, January 27, 1883, we learn that in the *Wiener Med. Woch.*, No. 50, Max Weiss has put on record a case of abscess of the brain occurring in connection with typhoid fever; and further, since gross lesions of the cerebrum in this disease are very infrequent, Max Weiss has prefaced the description of his case with notes of the literature of the subject. Griesinger, out of 118 cases of enteric fever, met with four instances of effusion of blood between the arachnoid and dura mater (there was no pachymeningitis, which is one of the most frequent causes of hæmorrhage in this site); in two this happened in the third week of illness, in two in the marasmus after the disease had ceased. Buhl, out of 300 cases, met with two of softening with capillary hæmorrhage in the substance of the brain. Tommaso Galli has communicated an instance of aphasia occurring in the course of convalescence. Berger has recorded a case of left

hemiplegia, which set in suddenly, with only transient disturbance of consciousness in the course of the disease. Duchek has contributed three examples which were observed in an epidemic characterized by little diarrhœa and abundant rash. In these individuals the symptoms were those of irritation and paralysis combined. Thus, spasm of the face, with lockjaw and stiffness of neck, back, and extremities, were mingled with ptosis, dilatation of pupil, and convergent squint (the third and sixth cranial nerves being paralyzed); one case showed cutaneous hyperæsthesia, and another aphasia. The above reports are interesting, but, in the matter of diagnosis of gross cerebral lesion, evidence other than that obtained at the post-mortem table is apt to be misleading, and cannot be trusted—*e. g.*, the symptoms of cerebral tumor are often observed in cases of renal disease. The case recorded by Max Weiss was that of a single woman, aged twenty-one years, who, six days before death, was suddenly seized with vertigo, after which the left side was found to be paralyzed. In the progress of the illness the left limbs were also the seat of clonic and tonic spasm. At the post-mortem examination there was discovered an abscess in the "motor" region of the right cerebral hemisphere; in the ileum, signs of a past enteric fever in the form of small, flat, shallow scars; and perimetritis, with catarrh of the uterus and Fallopian tubes.

Secondary Puerperal Hemorrhage.

Dr. Paul F. Mundé read a very valuable paper on this subject before the New York Academy of Medicine (*Med. Record*, January 27, 1883). He refers principally to the fact that alarming uterine hemorrhage may occur as late as several weeks after confinement, and concluded his paper by making reference to the means of preventing these hemorrhages, both primary and secondary. The following rules were given for the management of the third stage of labor and the early puerperal state:

1. Always keep the hand on the fundus uteri from the moment the head appears at the vulva until the placenta is expelled.
2. Do not hasten the expulsion of the placenta too much.
3. Always watch the uterus with the hand, using gentle friction occasionally, for at least one hour.
4. Always give ergot by the mouth immediately after the birth of the child. If chloroform has been given, or if the labor has been unusually tedious, give ergot hypodermically, injecting a syringe of the fluid extract to the depth of one inch near the umbilicus.
5. If the uterus shows a reluctance to remain contracted, rub the fundus gently with a piece of ice, or insert a cone-shaped piece into the cavity.
6. Always make sure by palpation and percussion that the uterus contains no coagula.
7. Apply the child to the breast early.
8. Apply an equally tight binder, and, if there be tendency to hemorrhage, a pad should be placed over the fundus to secure its steady compression.
9. If there be laceration of the cervix or vagina,

future oozing may be checked by mild astringent injections, or, if need be, by applications through the speculum. Immediate suture for laceration of the cervix appeared to him to be rarely feasible.

10. Do not allow the lying-in woman to leave her bed before the tenth day.

11. See that the bladder is empty, and is not interfering with uterine contraction.

12. See that the nozzle of the syringe is not introduced too far, and that too much force is not used in giving the customary cleansing injection.

The Cutaneous Manifestations of Paludism.

The *New York Med. Jour.*, March 17, 1883, says:

In a paper on this subject by Verneuil and Merklen (*Ann. de Dermat. et de Syphil.*, Nov., 1882), the following are the conclusions arrived at:

1. Herpes is one of the common manifestations of malarial disease.

2. It may either precede the paroxysm of intermittent, or occur during any one of the three stages of the paroxysm, or it may follow the stage of sweating. It may appear even after the paroxysms of the fever have been suppressed by means of sulphate of quinine. There is no etiological connection between the herpes and the fever, notwithstanding their frequent coincidence.

3. Paludic herpes does not present any peculiar features. Its most common locations are the face, the region about the lips and nostrils, the eyelids, the cornea, and such points as are most abundantly supplied with nerves. Though ordinarily discrete, in certain epidemics the eruption presents a remarkable tendency to confluence.

4. Black crusts, or, more especially, black vesicles attending the herpes, pertain to grave and pernicious forms of malarial fever.

5. Exceptionally, the herpes of malaria takes the form of zoster.

6. The ordinary forms of malarial herpes may be preceded by and accompanied with vaso-motor disturbances upon the surface of the skin, and disorders of sensibility.

It is believed, in consideration of the habitual locations of the eruption, of its concomitant disorders, of its possible appearance in the absence of a febrile attack, that the cause of the disease is referable to a nervous lesion, perhaps to a congestion of the cutaneous nerve-branches, resulting from the localization of the malarial poison in these nerves.

dispels some common illusions, and depicts very forcibly and graphically their mischievous tendencies and results.

—The annual address before the New York Medico-Chirurgical Society by its President, Dr. E. P. Fowler, is very neat in typography and conservative and sensible in its contents. It discusses the meaning of such words as "disease," "cure," "recovery," etc., and has a few trenchant paragraphs on homeopathy.

—An odd and wild sort of a paper is one by Dr. Matthew Kempf, of Ferdinand, Ind., on the "Wandering Cainidæ," a supposed ancient nomadic race. It is a lecture delivered before the medical society of Dubois county, and is half prose and half quotations from a poem apparently unpublished.

—Dr. John G. Lee, of this city, has written an interesting essay on "Homicide and Suicide in Philadelphia from 1871 to 1881." It is a thoughtful presentation of the influences which lead to these two great crimes. Suicide is not on the increase in this city, and the author very properly draws the line between the act as deliberative and insane.

—Dr. John Homans, of Boston, furnishes 100 cases of antiseptic ovariectomy. The net result is 87 recoveries, 13 deaths. He adds: "This is about as well as I can do, unless I refuse the desperate cases." Well enough, too, we think, when we remember that only twenty years ago this operation was condemned by many leading physicians as wholly unjustifiable!

—"The Electric Light in Surgical Diagnosis," is the title of a valuable reprint by Dr. Roswell Park of Chicago. He believes that these various "scopes" are "capable of aiding us to a realistic knowledge of many diseased conditions to which we could not otherwise attain." The same writer has published an essay on "Secondary Batteries and the so-called Storage of Electricity," well worth reading by all who are studying this important topic.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—In the April number of *Lippincott's Magazine* one of the most striking papers is on "The Climate Cure," by Frank D. Y. Carpenter, who writes in a decidedly cynical vein, and who seems occasionally to overstate the argument against the claims of our principal health resorts, but who

BOOK NOTICES.

The Dispensatory of the United States of America. Fifteenth edition. Edited by H. C. Wood, M. D., Joseph P. Remington, Ph. G., and Samuel P. Sadtler, Ph. D., F. C. S., etc., Philadelphia. J. B. Lippincott & Co., 1883, pp. 1,928.

In the heavy task of revising and, in fact, largely rewriting the United States Dispensatory, its editors have been engaged closely for the last

three years. The changes they have introduced are numerous, some of them radical. All, however, are no doubt the result of careful consideration of the needs of the time.

Of these changes we may note as of major importance that Parts I. and II. of former editions are now united as Part I.; that a number of original illustrations, largely of microscopic work, have been inserted; that a complete list of the analyses of American mineral springs is added, and that the index has been largely increased. The mineral waters are indexed separately, but no index of diseases is made out, which is an omission to be regretted.

The most material alterations in which physicians are interested, are in the sections treating of the medical properties and uses of drugs, etc. These have been recast by Prof. H. C. Wood, in sympathy with his well-known theories, that therapeutics should be based on physiology, rather than on bedside observation. That such a pronounced advocate of what is, at least, a debatable theory, should have had the charge of a work of this general scope, may, perhaps, detract from its position as an unbiased authority, at least in those respects where it is most interesting to physicians.

The chemical portion has been under the charge of Prof. Sadtler, while Prof. Remington has given his attention more especially to the strictly pharmaceutical aspects of the revision.

The publishers have done their part with a great deal of judgment, and the volume, though bulky, is not inordinately so, and is well bound and neatly printed.

The Medical and Surgical History of the War of the Rebellion, Part III., Vol. II. Surgical History. Washington, 1883.

This magnificent volume is a worthy continuation of its predecessors. At no time previously has such a monument to the devotion of the surgical staff of an army been consecrated by the country which was aided by their endeavors. The text is 986 large quarto pages, the woodcuts are 510 in number, and there are 44 full-page, most admirably executed, chromo-lithographic plates.

This volume closes the surgical series of the Medical and Surgical History of the War of the Rebellion. It embraces wounds and injuries of the lower extremity, miscellaneous injuries, the complications of wounds (hemorrhages, tetanus, erysipelas, pyæmia, etc.), anæsthetics, *materia chirurgica*, and the transportation of the wounded. Full indices close the volume.

It is a subject of national congratulation that the Government authorities have been willing to put forth these volumes. They will prove to the historian of the future one of the main landmarks in the development of military surgery; and the practical benefit of the extensive induction from carefully recorded facts they will confer, will long remain as a testimony to one of the collateral advantages which even war brings with it.

The Pathology and Treatment of Diseases of the Ovaries. By Lawson Tait, M. R. C. S., etc. Fourth Edition. New York: Wm. Wood & Co., 1883. Clo., 8vo., pp. 357.

Diagnosis of Ovarian Cysts by means of the Examination of their Contents. By Henry J. Garrigues, A. M., M. D., etc. New York: Wm. Wood & Co., 1882. Clo., 8vo., pp. 112.

Mr. Tait's book has grown in the ten years since its first appearance, from the size of a prize essay, as it then was, into a treatise of considerable bulk. This growth has been a normal one. The author's constantly enlarging experience, the remarkable improvements which have taken place in abdominal surgery of recent years, and the much closer means of diagnosis which a decade brings with it, all demanded a material enlargement of his earlier editions. He has accomplished this faithfully and successfully, so that really there is no point in the study of ovarian disease that is not discussed with fulness in this volume. It is no doubt the best monograph on the subject in our language.

Dr. Garrigues confines his attention to the elucidation of one single disputed question in ovarian surgery; that is, whether the fluid of an ovarian cyst offers a reliable means of diagnosing the character of that cyst. How much need there was and is for this discussion is evident from the opinions entertained by the two writers before us. Mr. Tait writes (p. 146): "Professor John Hughes Bennet, Dr. Drysdale, Mr. Thornton, and several others, have all fallen into the error of believing that any one form of cell can be made diagnostic of these growths." Dr. Garrigues draws the conclusion (p. 103) that "by studying the physical, chemical, and microscopical characters of the fluid, it is almost always possible to diagnosticate ovarian cysts, even without knowing anything about the patient." Dr. Garrigues, however, also rejects Drysdale's "granular ovarian cell," which, indeed, he says is not a cell at all, but a degenerated nucleus.

Both these books should be in the library of every working gynecologist.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D.,) EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a quarterly, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for strictly in advance and directly to this office.

THE TREATMENT OF ACUTE RHEUMATISM.

While the chemical theory which refers the joint troubles and the cardiac complications to an acid circulating in the blood, (says Dr. Robert Bartholow, *Medical Record*, January 6, 1883,) receives support from clinical facts and from the results of experience, yet there is an influence behind those chemical processes, which is concerned in the secondary assimilation, to produce an excess of acid, and which, we have many reasons for believing, proceeds from the nervous system. It may be affirmed that joint affections closely related to rheumatism are caused by certain spinal and nerve lesions, and hence we may regard it as probable, if not proved, that in the treatment of acute rheumatism we have to deal with a neurotic affection. In spare persons of considerable bodily vigor, good muscular development, and having a distinct family history of neurotic or rheumatic disorders, who are prone to indulge in a rich diet of animal food, sauces and wines, and to pursue sedentary occupations, salicylic acid or salicylate of soda renders incontestible service, no doubt due to its power to diminish the irritation of the trophic nervous system. They should be given in full doses and continued after the subsidence of the acute symptoms, and the cessation of the fever and pain, for the same number of days as the acute attack lasted. Thus, if the decline of fever and pain occurred on the fourth day, the remedy should be continued as many days thereafter, or for four days subsequent to the apparent cessation of the acute symptoms.

The second class of rheumatic subjects contains the obese or those of full habit, the rotund addicted to malt liquors and to good living, all of whom are apt to suffer from a form of acid indigestion. The cases of rheumatism occurring in such subjects are, as a rule, much benefited by the alkaline treatment.

"By the 'alkaline treatment,'" says Dr. Fuller, "I mean a plan of treatment in which alkalies play an important part, but which consists not only in the administration of alkalies, but in the careful regulation of the secretions, the strictest attention to diet, and the administration of

tonics, such as quinine and bark, as soon as the patient can bear them. * * * My practice is to give not less than an ounce and a half of the alkaline carbonates, either alone or in combination with a vegetable acid, during the first twenty-four hours of treatment. * * * More commonly two drachms are ordered to be taken in effervescence every three or four hours in combination with an ounce of lemon-juice, or with half a drachm of citric acid dissolved in four ounces of water. At the same time, if the bowels are torpid, ten grains of colocynth and calomel pill (British Pharm.) are prescribed at bed-time. As soon as the urine, when freshly voided, ceases to show an acid reaction—which is usually the case after twenty-four hours—the quantity of the alkali is diminished by one-half, six drachms only being administered during the succeeding twenty-four hours. At the expiration of that time, if the urine remains alkaline, three drachms only are given in the next twenty-four hours; and on the fourth day, if the urine still shows an alkaline reaction, the form of the medicine is altogether changed. The treatment ceases to be essentially alkaline; either a cinchona draught is ordered to be taken three times a day, containing a scruple or a half drachm of bicarbonate of potash—a little more or a little less, according to the condition of the urine, which should be kept nearly neutral—or three grains of quinine dissolved in lemon-juice is given three times a day in effervescence, with half a drachm of bicarbonate of potash or soda. * * * The diet is restricted to beef-tea or broth, with soda-water and milk, and barley-water as a drink, as the smallest quantity of solid food, given a day before the tongue has thoroughly cleaned, is apt to induce a recrudescence of the disease. Wine and spirits are strictly forbidden, though experience has convinced me that wine and spirits prove less hurtful than the smallest quantity of solid food.

“In my experience, the special peculiarity of acute rheumatism in these obese subjects is the tendency to assume a sub-acute character, and to be delayed in the progress toward recovery. They are also more liable to heart complications.”

The alkaline treatment, carried out as above described, gives better results in respect to relief to suffering, to duration of the disease, and freedom from complications.

The third type of rheumatic cases and numerically the most important—probably, also, pathologically, the most serious—is the feeble and anæmic subject. A rheumatic of this kind is pale, rather thin, the muscles weak and wanting in firmness, the chest narrow and somewhat flat, the joints prominent and lax. In such persons an extension of the rheumatic inflammation from joint to joint, until almost all the joints of the body are involved, is to be feared, as it is of frequent occurrence. Cardiac complications are relatively frequent. It need hardly be observed that in such subjects the depressing effects of salicylic acid and the alkalies are to be dreaded. Here clinical experience is in entire accord with theory. We owe to Dr. Russell Reynolds, of London, the introduction of a remedy for acute rheumatism, which is especially suited to this group of cases. I refer to the *tincture of the chloride of iron*. To be effective, it must be given in full doses—from ʒss. ʒj. in sufficient water, every four to eight hours. It lessens the swelling and pain of the joints, lowers the fever, diminishes the tendency to heart complication, and, above all, sustains the vital powers in their struggle against the encroachments of the rheumatic disease.

A combination of the blister treatment with salicylic acid, with alkalies, or with the tincture of iron, may often be made with signal advantage.

It will sometimes produce strangury. Milk and animal broths should constitute the exclusive diet until the cessation of all joint troubles; and atropine (if efficient) is preferable to morphia as an anodyne.

PROTECTION FROM YELLOW FEVER.

It does seem difficult to impress upon our people the importance of sanitary precautions; but when once taught their significance by great calamities, there are many among us wise enough not to forget or neglect their dearly-bought experience.

There is still lingering in the minds of the majority a distrust of the results of investigation and of the preventive and protective power of hygiene; they preferring rather to give adherence to the barbarous, superstitious, and exploded view of the inevitability of disease and its visitation upon man as a punishment for wrong-doing.

That it is not inevitable, we, who read hygiene, full well know; that it is a divine visitation as a punishment, we also know; for could a people more thoroughly merit punishment than when they wilfully and deliberately neglect the warnings, the writings, and the words of those earnest philanthropists who study that they may learn how to prevent and control disease, and write, that they may impart this almost divine knowledge to their fellow-men?

We would ask whether, in the light of accepted sanitary dogmas, the city of Philadelphia does not eminently deserve the most serious punishment that the most severe epidemic could inflict upon her, when her people put into control men who outrage all sanitary laws, and who permit our streets, for months at a time, to remain in a condition in comparison with which the foulest pig-pen would be a model of cleanliness? When the rains of spring are succeeded by the heat of summer, who can foretell how terrible may be the ravages of epidemic diseases in our midst?

Poor fever-stricken Memphis has learnt its lesson, and we all remember at what a terrible price.

We learn that the authorities there, owing to the unsatisfactory condition of the laws governing quarantine at the mouth of the Mississippi, have decided on self-protection. The Legislature has been petitioned for an appropriation to defray the expenses of local quarantine in case of necessity. A thorough house-to-house inspection is being made, and every building, front and back yards, outhouses, stables, etc., will be thoroughly examined, with a view to having them put in the most complete sanitary condition.

The President of the Council backs up the proclamation with the warning that the owners of unsanitary premises will be punished to the full-

est extent of the law for violations of the sanitary ordinance. This system of inspection will be continued throughout the summer, and until all possibility of danger is passed. The first intimation of yellow fever or other contagious diseases, at New Orleans or other points on the lower Mississippi, will be the signal for the establishment of a rigid quarantine against the places. The troubles of 1878 and 1879 have not been forgotten, and the authorities are determined that they shall not be repeated, if it is in the power of man to prevent them.

NOTES AND COMMENTS.

Interstitial Tubo-Gestation.

In the *British Medical Journal*, Dr. Henry Haggood describes the case of a married woman, aged 35, who died with all the symptoms of internal hæmorrhage, in the eleventh week of pregnancy.

"At the necropsy, there were about five pints of clotted blood in the pelvic and abdominal cavities. On turning this out, the source of the hæmorrhage proved to be a sac, formed by the uterine portion of the left Fallopian tube and the wall of the uterus, which had grown outwardly to about the size of a walnut, and then ruptured anteriorly. Chorion villi were distinctly visible in the sac. The opening of the tube into the sac had become obliterated. There was evidence of a previous partial rupture, in the shape of a small hæmatocèle, on the posterior aspect of the sac. The fœtus had escaped into the abdominal cavity, and was unfortunately lost. The left ovary was closely attached to the left side of the uterus by old bands of lymph, and contained several cysts. The right ovary was normal, and contained a corpus luteum. The uterus was enlarged, and its lining membrane was red and thickened, forming a distinct decidua, that could be easily detached. The bladder was healthy, but contained no urine. The abdominal organs were healthy, but very anæmic.

"With regard to the cause of the arrest of the ovum in that particular spot, I may remark that nothing existed in the Fallopian tube or uterus, in the shape of polypus or fibroid, to cause obstruction, but that there were plenty of adhesions on the left side, matting the uterus, Fallopian tube and ovary together, altering their relative positions, and, possibly, causing obstruction. Yet the presence of a corpus luteum in the right ovary,

coupled with the cystic condition of the left, would point to the theory of transmigration of the ovum as being the most probable explanation of the phenomenon."

The Electrical Treatment of Enlarged Glands.

In the *Med. Press and Cir.*, January 17, 1883, Dr. Hercules H. MacDonnell recommends the following modification of Mr. Golding Bird's procedure:

Having selected the gland or mass of glands you purpose treating, have the surface well cleaned and wiped over with a solution of salt. Apply the negative pole of a Leclanché battery, having two cells connected, over the most prominent part, and the positive about three inches apart; keep moving the positive reophore in a circle round the negative quite slowly, till the electrical stimulus has been sufficiently applied. Usually, five to six minutes is long enough. On the first occasion two cells are enough, as it accustoms the tissues to the action. On the succeeding applications, the effect of additional cells may be tried; but should there be the slightest appearance of inflammatory action, as evidenced by a bluish-white tint under the negative reophore, a couple of cells must be at once disconnected, or the application discontinued on that occasion. I have never used more than eighteen cells continued for three minutes, and have found that from eight to twelve cells give the most satisfactory and rapid results. The length of each application varies for different individuals. In some patients three or four minutes twice daily seemed to suffice; in others a longer application only once answered better. Even different glands or masses of glands in the same individual, progressed more rapidly under varying conditions of length, strength, and frequency of application.

Fair-skinned patients bear a more heroic line of treatment better than dark ones, and react more quickly to the electrical stimulus.

Naphthol in Itch.

The *Med. Times and Gaz.*, February 3, 1883, says:

Introduced by Prof. Kaposi, of Vienna, naphthol has been substituted by him for tar in some affections of the skin, as eczema, psoriasis, prurigo, and especially itch. It has scarcely any odor, and even after long exposure to air only becomes of a pinkish color, which does not permanently stain the linen. Prof. Hardy, it is stated in a *thèse* by Dr. Guérin, has substituted a very simple formula for the complicated one of Kaposi,

consisting in vaseline 100 parts to 10 parts of naphthol. The pulverized naphthol is dissolved in half its weight of ether, and is then mixed with a portion of the vaseline, and heated to 30° to 40° Cent., until the ether is entirely evaporated. The rest of the vaseline is then added, and the mass carefully triturated. The homogeneous pomade which is produced is kept secluded from the air. It may be applied at all periods of itch, whether complicated or not; and it is applicable also to the eruptions which supervene in the course of itch, and for which sulphur ointment is unsuited. The furrows are by this ointment rapidly freed of their inhabitants, and other eruptions disappear. The treatment lasts from ten to fifteen days, which is very much longer than Prof. Hardy's rapid treatment by sulphur; but when we consider how long the itching persists often after the cure by sulphur—sometimes obstinately continuing for months—the treatment by naphthol is practically the shorter of the two. M. Guérin has never observed any ill-effects upon the kidneys result from naphthol.

Hysterectomy.

This being still a comparatively rare operation, the following case is worthy of record (*New York Medical Journal*, January 27, 1883): The patient first came to the Woman's Hospital five years ago, suffering from precidentia of the uterus, which was partially relieved by certain plastic operations on the vagina. Last spring Dr. Emmet performed Le Fort's operation, which proved successful; but some months afterward the patient gave way to a fit of anger, and the uterus, which contained a large fibroid tumor, was again crowded down toward the vulva. The patient was suffering greatly from pain, and desired to have the tumor removed. Dr. Emmet performed the operation, removing the body of the uterus with a portion of the cervix, the ovaries, and the tubes. The mass was composed of eight fibroids, mostly intra-mural. In order to avoid hæmorrhage, Dr. Emmet made use of a plan first introduced, he believed, by Olshausen, but since constantly practiced in England, viz., that of encircling the whole mass at its base by a long piece of Esmarch's tubing prior to its amputation. This tubing, being put about the tumor at full tension, was grasped at the point of crossing of the two extremities by a strong forceps, and this was firmly held by an assistant. Prior to the removal of this constrictor, he secured the stump in the Kœberlé serrenœud, having previously transfixed it with two needles. The abdominal wound was then

closed, and the pedicle was thoroughly smeared with Monsel's salt. At the present time, the beginning of the fifth day, the patient was doing well.

A New Treatment of Dysentery.

Dr. F. Rawle recommends the following treatment in the *Brit. Med. Jour.*, January 27, 1883:

First, having placed the patient between warm blankets, I proceed to inject a pint and a half of warm water, at a temperature of 90° Fahr. This is seldom retained longer than a few minutes, but is pronounced very grateful to the patient. When the water has soothed the mucous membrane of the colon and rectum, and brought away any *effete* matter, I then proceed to administer a small injection of two ounces, by measure, with a gum-elastic bottle. The form I administer is the following:

R. Quinæ disulphat.,	gr. x.
Tinct. camphoræ comp.,	3 iv.
Decoctum amyli ad	3 ij.

M., and when about milk-warm, inject.

It is generally retained, but if ejected, it may be repeated after an hour or two. This I have found of great service, and very grateful to the patient. I do not stop to inquire how it acts, but the effect is like magic. If griping pains be felt over the region of the epigastrium, I administer half-drachm doses of chlorodyne, in some aromatic water, mint, caraway, or aniseed. The diet, of course, should be of the most soothing kind: jellies, isinglass, linseed, toast and barley water, *ad libitum*. Ipecacuanha I have found of little service, and have discarded it from my treatment. If any of my medical brethren will try these measures, he will not often be disappointed. I have used with advantage warm turpentine stupes on warm flannels, over the hypogastrium.

Œsophagotomy.

On September 4, 1882 (*Med. Times and Gaz.* January 13th, 1883), external œsophagotomy was performed in the Kommune hospital at Copenhagen by Dr. Holmer. The patient, a man aged thirty, was a lunatic who had swallowed a stone with suicidal intention two days before. The foreign body became impacted in the gullet a little below the larynx, and could not be dislodged either upwards or downwards. The accident was further complicated by the "cradle" of Gräfe's coin-catcher having become detached during the attempts to extract the stone, and remaining in the gullet. Dr. Holmer then made an incision along the anterior border of the sterno-mastoid muscle,

and opened the œsophagus over the site of the impacted substances. The little "cradle" was first removed, and, after a good deal of trouble, the stone was seized with a pair of forceps such as are used for lithotomy in children, and extracted. The stone was found to be five centimetres long, by five centimetres wide at its broadest part. The wound was dressed with iodoform, and the patient made a rapid recovery. His voice, however, remained hoarse, owing to paralysis of the left vocal cord. This was possibly due to injury of the left recurrent nerve during the operation, but Dr. Holmer thinks it more probable that it was caused by the pressure of the stone, as the patient's voice was husky when he first came under observation.

Iodoform in Puerperal Fever.

The *Am. Jour. of Obstetrics*, February, 1883, says that Maggioli of Rome, in the *Gaz. Med. di Roma*, viii. 1, agrees with Spiegelberg in the necessity of applying antiseptic principles to the treatment of puerperal cases, but not entirely in what Spiegelberg calls secondary antiseptics. Iodoform internally is useful in puerperal cases for many reasons: it is readily absorbed and readily tolerated by the mucous membrane of the stomach and intestines: it is readily diffused, and the iodine is found (after the administration of iodoform) in the urine, saliva, tears, sweat, milk, nasal mucus, menstrual blood, and in the air expired from the lungs. The iodine reaction may be obtained from the urine as late as four days after the administration of the last dose. From two to three grammes may be given daily without harm. Nine-tenths of the weight of a given quantity of iodoform consist of iodine. The generally accepted beneficence of this substance as a topical application suggests its utility as a means of internal medication. The author's experience is limited to four cases of puerperal fever, in which the results were very favorable. Two additional cases were treated by Moleschott, the substance being used in the form of an unguent and rubbed into the skin.

A New Operation for Spina Bifida.

From the *Brit. Medical Jour.*, December 30, 1882, we note that Mr. Robson recently performed a new operation for spina bifida on a child six days old. After the redundant parts were removed, and after stitching up the arachnoid over the spinal canal, periosteum from a rabbit was inserted between the meninges and the skin, so as to cover the gap in the bones. The wound had perfectly healed; the skin over the lumbar region

was quite level; there seemed to be no tenderness on pressure; the child looked strong and healthy. The sac was found to be of the size and shape of half a swan's egg; the wall consisting of true skin and subcutaneous tissue lined by serous membrane. Mr. Robson drew attention to the following points:

1. The operation was performed with full antiseptic precautions, eucalyptus air being used instead of carbolic spray.

2. The meninges were closed by uniting the serous surfaces, as in peritoneal surgery.

3. The transplantation of living periosteum and its continued vitality; it had not yet, however, formed new bone, but already the covering of the canal had a greater than mere skin-firmness.

4. The entire absence of bad symptoms in the child, operated upon at so early an age, was noticed.

Results of Excision of the Pylorus.

The *Med. Times and Gaz.*, January 27th, 1883, says that Dr. Rydygier, in a recent number of *Volkmann's Sammlung*, thus sums up the results of the operations hitherto performed. Sixteen surgeons have operated upon twenty-three cases, all but two of which have been examples of cancer. Of these last two operations one was performed by Rydygier in a case of stenosis caused by round ulcer, which terminated successfully; and the other by Lauenstein in a case of supposed cancerous tumour, which at the autopsy proved to be one of gangrene of the transverse colon. Of the twenty-three cases, nineteen proved fatal, viz., fifteen some hours after the operation, three on the seventh or eighth day, and one (Billroth's) four months after, from relapse. Of the four recoveries, one belongs to Billroth (no relapse having occurred in six months), one to Wölfler (the patient seeming well at the end of a year), one to Czerny (seven months without a relapse), and one to Rydygier.

Dr. Cattaneo's Treatment of Hydrocele.

From the *Jour. de Med. de Paris* we note the following treatment recommended by Dr. C.:

1. Puncture of the hydrocele with a capillary trocar of an aspirator, and evacuation of the fluid.

2. Injection of a solution of hydrate of chloral in quantity proportionate to the volume of the hydrocele and age of the patient: one to two grams of chloral for children, four grams for adults, and occasionally more in old men. The solution is made by dissolving equal parts of chloral in cold distilled water.

3. Cold applications, to overcome the pain produced by the injection.

4. The injection is repeated if the absorption occurs too slowly.

The patients are kept in bed, and wear a suspensory bandage for some time after the termination of treatment. Dr. Lampagnani says that the effusion has not returned in any one of the seventeen cases operated upon by this method.

Labor Complicated by Lipoma of Labium Majus.

In the *Centralbl. für Gyn.*, Bruntzel records the case of a primipara in which a tumor, the size of a hen's egg, had existed for four years, which had never given any trouble, save an occasional prolapse after severe efforts. After she had been in labor twenty-four hours, the tumor was drawn out and held to one side by means of a towel, and the child was delivered with the forceps without rupturing either the perineum or the tumor. The latter had seemed to develop on account of the pressure which had been brought to bear upon it during the labor, and afterward seemed harder and less movable. The latter facts caused a change in the diagnosis, which had originally been that of hernia labialis. Three months later the tumor was removed, as it had become a source of great annoyance to the patient.

Uraemic Seizures.

The *London Med. Record*, Feb. 15, 1883, says:

Dr. Rühle (*Trans. of German Med. Congress*, 1882,) states that in every case of death from uraemic convulsions, oedema of the brain is found to exist. But simple oedema of the brain does not cause convulsions, and some toxic agent must be added to the serous exudation to produce this condition. That chemical changes accompany the uraemic attacks, is shown by the fact that the gastric secretions become alkaline, and that the breath turns litmus-paper blue. So soon, therefore, as oedema of the brain comes on in the course of these, as yet, undefined blood-changes, it acts as a poison and gives rise to convulsions.

Nervous Cough.

Before a recent meeting of the Boston Society for Medical Improvement (*Boston M. and S. Jour.*, March 29, 1883), Dr. Bowditch reported a case of cough lasting sixteen months, apparently, except for the duration and violence, a case of typical whooping-cough. Laryngoscopic examination showed nothing. At the lowest part of the chest, outside the heart, was crepitation for a space of

one or two inches, but no dullness. He supposed the cough to be nervous.

Dr. Knight said that he had seen many cases of what he thought nervous cough, and which were usually benefited by nerve sedatives. One case had yielded to enormous doses of quinine, beginning with two grains, and gradually reaching fifteen or twenty at a dose.

Surgical Treatment of Intestinal Obstruction.

In acute intestinal obstruction that will not yield to massage, cathartics, and enemata, Dr. Krönlein (*Correspondenzblatt für Schweizer Aerzte*, Nos. 15 and 16, 1882), recommends laparo-enterotomy. An incision is made in the right iliac region, and the portion of the gut which presents at the opening is seized and stitched to the abdominal wall. If the intestinal canal become permeable again, the artificial anus may be closed; but, in any event, he does not consider that life with an artificial anus is so unendurable as many are accustomed to suppose.

Electrical Treatment of Epigastric Pains in Hysteria.

The *Chicago Med. Jour.*, Feb., 1883, says: These pains, which are mostly accompanied by severe vomiting, have been successfully treated with the galvanic current by Dr. Apostoli. The positive pole is applied in the subclavicular region, and the negative pole over the seat of the pain. It is continued for 5 to 15 minutes, and it is said to have stopped the vomiting entirely. The gastralgia and epigastric pains have been stopped after ten to fifteen applications.

The Frequency of and Danger from Narrow Pelvis.

The *Medical Record*, January 6, 1883, says that Dr. W. Fishel read a paper before the German Medical Society of Prague, in which he stated that the usual estimates of the frequency of narrow pelvis in Germany were too high. These estimates made the proportion vary between 14 and 20 per cent. Hecker, of Munich, found the per cent. to be only 1.5; Müller, in Berne, 16; Goerner, in Basel, 7; Winckel, in Dresden, 3; Fishel, in Prague, 15.6. In Breisky's clinic, at Prague, the mortality in these cases was only 1.5 per cent.

Spontaneous Separation of the Funis.

Dr. Burge reported the following case to the Rhode Island Medical Society (*Boston M. and S. Jour.*, March 29, 1883):

While the mother was attempting to rise from the bed, the child was born, and dropped to the

floor, breaking the funis about five inches from the umbilicus. Dr. Burge arrived soon afterwards, and found the child alive and crying vigorously. He ligated the cord as a matter of routine, though there had been no hemorrhage.

Rupture of the Pulmonary Artery.

A man, apparently in perfect health, was suddenly attacked with severe pains in the chest and extreme anxiety and difficulty of respiration, which, after thirty hours, terminated in death. Dr. Arro, who reports the case in the *Rivista de Ciencias Med.*, December 10th, 1882, found at the autopsy a rent in the pulmonary artery, from which a large amount of blood had escaped into the chest.

A New Protective.

* Dr. Malinin (*Mediz. Obozr.*) recommends mixing, collodium lbj, castor oil 3j, almond oil 3ss, and carbolized oil 3iij-3iv, and spreading it over a glass plate smeared with glycerine. The fluid rapidly dries, forming a transparent, thin, soft, and light sheet, which, when used, suffers no alterations from the contact with wound-discharges, and may be employed repeatedly (of course, each time after its washing in a carbolic solution).

CORRESPONDENCE.

Consulting Clairvoyants.

EDS. MED. AND SURG. REPORTER:—

Your reply to "Dr. T. W. E., of Ohio," relative to the absurdity of consulting clairvoyants by sending a lock of hair, reminds me of an incident occurring in my own practice several years since, that is too good to be lost. I had a patient with mitral regurgitation, and some of the officious old women who thought I might be mistaken in my diagnosis, advised the wife of my patient to send a lock of his hair without his knowledge to a notorious clairvoyant, which she did, but without stating the sex of the patient. In due course of time a reply came back from the clairvoyant, that after "going through the patient's system" she found the trouble to be *ulceration of the womb*, and that if the patient was placed under her special care, she would readily cure, etc. It is needless to state that she failed to convince Mrs. — that her husband had any such physiological appendage, with its attendant diseases.

Stonington, Conn.

GEO. W. STANTON, M. D.

Prof. Smith's Frequent Repetition.

EDS. MED. AND SURG. REPORTER:—

You quote from the *N. Y. Med. Jour.*, an article by Dr. A. A. Smith, Professor of Materia Medica in Bellevue, which you call "valuable," and which, if true, is not only valuable but a trifle startling.

Here we find it gravely stated that half a drop of Fowler's solution will cure the vomiting after a debauch.

That in *pseudo* croup a single teaspoonful at a dose of a solution of one one-hundredth of a grain of *atropine* in a glass of water will give prompt relief.

That drop doses of *chamomile* will quickly relieve many complaints of nervous babies.

That a single drop of wine of *ipecac* will often produce the most marked relief both from vomiting and diarrhoea.

That teaspoonful doses of a solution of *corrosive sublimate*, one grain to a quart of water, is curative in mucous passages from enteritis.

That another extraordinary statement, which at first seemed to me to be "fabulous," is, "put a grain of *tartar emetic* into one quart of water: teaspoonful doses every half-hour will relieve the wheezing and cough accompanying a slight bronchitis in children."

Further on: *cantharides* in insignificant doses is recommended in vesical catarrh; single drop doses of *digitalis* in heart affections; *castor oil* in diarrhoea; *pulsatilla* in orchitis and dysmenorrhoea; *ergot* in amenorrhoea; *aconite* in fever, with bounding pulse and hot, dry skin; and more of the same sort.

Now I confess I was set back by an article in your journal some five years ago, by Charles H. Hall, M. D., upon *corrosive sublimate* in dysentery, in which he claimed remarkable success with "small and frequently-repeated doses," frankly admitting that the principle and practice was homeopathic, and boldly charging Ringer, who recommends it, with plagiarism. Hall says, "Any one who is curious on the subject of his small doses, not only in this disease, but in almost every other one of his recommendations, has only to refer to homeopathic works, and find that he has plagiarized."*

But here is more of the same kind, and by a Professor of *Materia Medica*. Does it not strike you, Messrs. Editors, that Prof. Smith's recital of therapeutic wonders is overwhelmingly open to the same criticism? Upon what principle does he studiously ignore the source of his practice? It would certainly redound to the credit of the profession if a more frank and manly stand were taken in just such matters.

Pittsburgh, Pa. J. H. McCLELLAND, M. D.

(Prof. Smith is a distinguished gentleman, and the journal from which we noted his remarks is reputable. If he derives his practice from the source our correspondent assumes, he is perfectly right, and Prof. Smith should openly state that such is the case—EDS. REPORTER.)

NEWS AND MISCELLANY.

Medico-Chirurgical College.

The commencement exercises of the Medico-Chirurgical College took place in Association Hall on the evening of March 29.

After prayer by Rev. John B. Dales, the address to the graduates was delivered by the Dean of the Faculty, Prof. William S. Stewart, who concluded

by conferring the degrees. The prizes were awarded as follows:

Faculty prize of a gold medal for the best thesis and examination, to Henry Fisher, with honorable mention of Frederick Loos, Jr.

Especial honorable mention of the thesis of Richard Vallancey Danne, for its elaborate character and unusual excellence.

Especial honorable mention of the examination of Mr. Frederick Loos, Jr., he having passed the best examination before the adjunct faculty.

Mitchell Chemistry prize of a Beck's Histological and Dissecting Microscope, awarded by the Professor of Chemistry for the best thesis upon a subject in medical chemistry showing original research, to Frederick Loos, Jr., with honorable mention of the theses of Henry Fisher and Emil M. Herwig.

Surgical prize of a gold medal, awarded by the Professor of Surgery for the best thesis and final examination upon surgery, to Bernard Marquis Goldberg, M. D., with honorable mention of the examination of Julian Frank Meade.

Prizes by the Adjunct Faculty.—A prize of a laryngoscope, awarded by the Professor of Diseases of the Throat and Upper Air Passages for the best examination in his branch to Frederick Loos, Jr.

Christine prize to John S. Stewart.

Rev. Dr. Richard Vallancey Danne, of Melbourne, Australia, delivered the valedictory.

The Charges against Drs. Beates and McDowell Withdrawn.

The charges of conspiracy preferred against these gentlemen have been withdrawn, as testified by the following letter:

DEAR SIR: I am satisfied upon reflection that I was wholly mistaken in believing that any conspiracy had taken place between you and Dr. McDowell to obtain any part of the property of Catherine Potts, now deceased, or for any other purpose; no such conspiracy, or any conspiracy, I am now satisfied, ever existed on the part of either of you. I admit that anything that I may have testified in the above suit before Magistrate Robert R. Smith to that effect was incorrect, and that I was mistaken*therein, and that I desire to withdraw all charges to that effect against either of you which I have made, as I am now satisfied of my error, and desire to make every reparation in my power to both of you. I regret extremely the publicity given to the matter, and authorize you to make any use of this letter you wish. For these reasons, and with the approval of both my counsel, I have requested that a *nolle pros.* may be entered in the above suit, and I learn that the same has been done with the approval of Magistrate Smith, of the District Attorney, and of Judge Yerkes. Hoping this may in some degree excuse what I formerly did, I remain yours respectfully,

JOSEPH B. NAULTY.

To Henry Beates, Jr., M. D.

Right-Handedness.

From the *Bost. Med. and Surg. Jour.*, March 29th, 1883, we learn that Dr. Goëtan Delaunay has communicated an interesting paper to the French Anthropological Society, in which he seeks to establish that right-handedness is not an acquired

* MEDICAL AND SURGICAL REPORTER, March 30, 1878.

habit, but is a natural attribute characteristic of the superior races. Savage tribes, he states, and communities in an inferior state of civilization, show a much larger proportion of left-handedness than highly civilized peoples do. Idiots and epileptics offer a very large percentage of left-handed individuals, and there are more left-handed women than men. His general conclusion is that in the evolution of the species there has been a steady tendency to the development of the right side of the body at the expense of the other, and that the examples of left-handedness still to be met with in the superior races are mere "survivals."

Therapeutic Improvements.

American Lint.

Among recent surgical improvements should be named in the first line a form of lint brought forward by Messrs. Seabury & Johnson. They produce it directly from the best quality of cotton, and from a careful examination which we have recently made of it, we place it as easily equal to the first-class products of foreign makers.

Jensen's Beef Peptones.

These excellent preparations deserve the attentive consideration of the physician. They find their place in the nutrition of infants, convalescents, dyspeptics, the aged, and those of impaired assimilation generally. Dr. Jensen has studied most thoroughly the methods of obtaining these organic products in a pure and palatable form; and from some personal experience and observation with them, we can say that he has reached a most successful result.

Mortality Rates.

In some of the principal cities of the world the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows: Calcutta, 34; Bombay, 25; Madras, 33; Paris, 26; Geneva, 18; Brussels, 23; Amsterdam, 26; Rotterdam, 29; the Hague, 26; Copenhagen, 21; Stockholm, 22; Christiania, 21; St. Petersburg, 45; Berlin, 22; Hamburg, 23; Dresden, 23; Breslau, 26; Munich, 28; Vienna, 24; Prague, 25; Budá-Pesth, 26; Trieste, 31; Rome, 23; Turin, 20; Venice, 26; New York, 21; Brooklyn, 21; Philadelphia, 19; and Baltimore, 27.

An Ingenious Device for Supporting a Hospital.

Mr. Arthur Keugh, of London, has hit upon an ingenious plan for getting funds for the Dental Hospital. He has started a "cigar thrift fund." He places boxes in cigar shops, clubs, smoking-rooms, etc., in which the ends of cigars can be placed. They are valuable enough, if the system is sufficiently widespread, to bring in a considerable sum of money annually. There is also a small cigar-cutter for the waistcoat pocket which preserves the tips, and these gentlemen themselves can save and forward.

Rhode Island Delegates to Am. Med. Association.

The following gentlemen have been elected delegates from the Rhode Island Medical Society to the American Medical Association: W. E. Anthony, D. H. Batchelder, W. S. Bowen, W. J. Burge, S.

B. Church, S. W. Francis, G. D. Hersey, S. Hunt, J. Kenyon, G. H. Kenyon, C. B. Mathewson, H. G. Miller, C. W. Parsons, H. J. Pomroy, F. H. Rankin, A. A. Saunders, G. W. Stanley, O. C. Wiggin.

Pensions.

The Pension Bill was passed by Congress January 13th. The following are some of the items: For army pensions, \$80,000,000; for navy pensions, \$1,000,000. Fees and expenses for examining surgeons, \$275,000. The allowance of from \$12 to \$35 per month is made for the loss of an eye, and \$50 per month for both eyes, while the loss of hearing is estimated at \$25 per month.

Items.

—An ophthalmic and aural book club has been started in this city, Dr. L. Webster Fox, secretary.

—A six-year-old's idea of the umbilicus. While studying his anatomy during the administration of a bath, this hopeful (son of a physician) remarked: "Mamma, I think the navel must be where I was finished off."

—Spirit of turpentine is now made from sawdust and refuse of the saw-mill. It is extracted by a sweating process, and yields 14 gallons of spirit, 3 to 4 gallons of resin, and a quantity of tar, per cord. The spirit produced has a different odor from that produced by distillation.

—A dealer in boots and shoes, to make his sign striking, had lettered upon it, "*mens conscia recti*." A rival in the vicinity, wishing to outdo his competitor, had his sign emblazoned with "*mens and womens conscia recti*." The latter was not in good Latin, but it drew the most customers.

—It is a Hebrew proverb, "When the sun rises the disease will abate." It originated from a tradition that Abraham wore a precious stone round his neck, which preserved him from disease, and which cured sickness when looked upon. When Abraham died, God placed this stone in the sun.

—A medical student at Bowdoin College once asked the late Prof. Parker Cleaveland if there were not some more recent works on anatomy than those in the college library. "Young man," said the professor, "there have been very few new bones added to the human body during the last ten years."

—It is stated that an employer of young men in Manchester, England, has decided that he would not allow salaries to any of his clerks who were injured in foot-ball matches, "as the game was too dangerous to be played with safety, and he did not feel it right that he should pay for absences caused in this manner."

—James T. Fields used to tell this story of Dr. Channing: "The reverend doctor and the medical doctor were both at a party in Boston one evening, and some one being taken ill, the man of medicines, Dr. Walter Channing, was summoned. The servant entered the room where the brothers were seated, and said, 'Dr. Channing is wanted.' 'Which Dr. Channing?' said Walter the physician; 'the one who preaches, or the one who practices?'"

Notice the Wrappers!

As we now print the address of subscribers on the wrappers of the *REPORTER*, and add to it the date to which they have paid their subscriptions, we beg all readers to notice the date, and remit if they are in arrears. If this is promptly attended to, it will save the business management of the journal the annoying necessity of sending bills or "duns," which are always unpleasant to receive and to present.

OBITUARY NOTICES.**GENERAL JOSEPH K. BARNES.**

General Joseph K. Barnes, ex-Surgeon-General U. S. Army, died of Bright's disease on the morning of April 5th.

He was born in Philadelphia, July 21st, 1817. Graduating from the University of Pennsylvania in 1838, he served a term in Blockley Hospital, was district physician for a while, and finally was appointed Assistant Surgeon in the army, June 15th, 1840.

In November of the same year he was sent to Florida, where he saw his first field service in Gen. Harney's famous expedition to the Everglades, in the war against the Seminole Indians. He remained with Gen. Harney's command in Florida two years, and in 1842 was transferred to Fort Jessup, an old-time military station in Louisiana, where he served until its abandonment, four years later. At the breaking out of the Mexican war in 1846, the young surgeon, then only twenty-nine years of age, was appointed chief medical officer of the cavalry brigade, and in that capacity he participated in every action of the war in either Gen. Taylor's or Gen. Scott's lines, excepting that at Buena Vista, and at the close of the hostilities was placed in charge of the general army hospital at Baton Rouge, La. For the next few years he rendered valuable service to the Government in organizing medical posts at various stations in Texas and throughout the West, acting for a short period as Medical Director of the Department of Oregon. He was assigned to duty at West Point again in 1854, and served there several years. In 1856 he received his commission as a Surgeon.

At the outbreak of the war of the Rebellion, Surgeon Barnes was stationed in Oregon, and was among the first officers to be called to Washington. In 1861 he was assigned to special duty in the office of the Surgeon-General at Washington, where his experience in field and hospital service was of great value to the Government. Two years later he was promoted to be a Medical Inspector, with the rank of Lieutenant-Colonel, and a few months afterwards he was appointed Medical Inspector-General, with the rank of Colonel. In September, 1863, he was made Acting Surgeon-General, and one year later, on the dismissal of Surgeon-General Hammond, was promoted to fill the vacancy, with the rank of Brigadier-General. He served during the war with great honor, and in 1865 received the brevet rank of Major-General. He was the first physician called to the bedside of President Lincoln when he was assassinated, April 15, 1865, and had charge of the case until its fatal termination. On July 2, 1881, when the late President Garfield was shot, he was among

the first physicians to be summoned to the White House, and served on the consulting board of physicians until the death of the President, giving the case his closest attention. He was placed on the retired list last year by the operation of the compulsory retirement law, and has since then been living quietly at his residence in Washington.

The General had a fine, erect, military bearing. His complexion was rich and ruddy, and his hair iron gray. He was agreeable in his manners, and socially was a wonderfully entertaining conversationalist. In his profession he stood deservedly high, and was universally respected by all who knew him.

He was buried in Oak Hill Cemetery on Saturday, April 6, the following gentlemen acting as pall-bearers: Gens. W. T. Sherman, Edmund Schriver, D. H. Rucker, W. H. Emory, A. Baird, M. C. Meigs, R. C. Drum, R. MacFeely, N. W. Brown, C. H. Crane, C. M. Wilcox, and Joseph E. Johnstone.

M. P. BARKER, M. D.

Dr. M. P. Barker, of Newcastle, Pa., author of a series of articles on "Medical Missions in Heathen Lands," which recently appeared in the *REPORTER*, died March 31, 1883. He was born in Sandy Lake, Mercer county, March 27, 1829. Was a graduate of Cleveland Medical College, and of the University of Pennsylvania. He located in Newcastle in 1861, and soon built up a large and lucrative practice. He was a thoroughly conscientious and skillful physician, and his life record was written in deeds. He was thrown from his horse about three years ago and received injuries of a serious character, which finally culminated in his demise. He was a member of the Presbyterian Church, holding the office of elder since 1865. Three daughters (his wife having died a few years ago) are left to mourn the loss of an affectionate father, and the community in which he lived will feel the loss of a talented and kind-hearted citizen.

S. S., M. D.

MARRIAGES.

COLE-SMITH.—At Pelleville, N. J., Wednesday, April 4, by the Rev. William M. Sanford, Theodore Cole, M. D., of this city, and Miss May Smith, of Hatfield, Mass.

DEATHS.

BAILEY.—At Bailey Homestead, Kent Cliff, Putnam county, N. Y., Dr. Joseph H. Bailey, U. S. Army (retired), in his 80th year.

HEADLEY.—In New York, Saturday, March 31, at his late residence, William S. Headley, M. D.

SHACKELTON.—On Sunday, April 1, at his late residence, Mattawan, N. J., Judson G. Shackelton, M. D., in the 47th year of his age.

TUNSTALL.—On April 1, 1883, at his residence, Norfolk, Va., Dr. Robert B. Tunstall, in the 63th year of his age.

VAN BUREN.—In New York city, March 25, No. 1 Park Avenue, Dr. William H. Van Buren, in the 64th year of his age.

SUNDBERG.—On March 19, 1883, Cynthia, wife of Dr. John C. Sundberg, of Seattle, W. T.

Dr. John W. Ferguson, lately from Charleston, was found dead just beyond the city limits on April 1. He is supposed to have committed suicide by poison.

Dr. Nathaniel Low died at Dover, N. H., April 2, aged 90 years. He was graduated at Dartmouth in 1839, and held numerous offices of trust in New Hampshire and Maine.

NOTES ON THE TREATMENT OF WHOOPING-COUGH.

BY W. THORNTON PARKER,
Acting Assistant Surgeon U. S. Army.
Of Fort Elliott, Texas.

In the *American Journal of Medical Sciences* for January, 1883, is a quotation from the *Lancet* of October 21, 1882, as follows:

"At the meeting of the Medical Society of London, held October 16, Mr. Dolan read an abstract of his essay on Whooping-Cough, to which had been awarded the Fothergillian Medal of the Society. * * * Turning to the question of treatment, he pointed out the necessity for measures of *isolation* in preventing the spread of the disease, for the enforcement of which measures the co-operation of all classes of the community was needed; and although the course of the disease *could not be controlled by treatment*" (the italics are ours) "the patient could be placed in the most favorable circumstances towards recovery; certain painful and prominent sources of trouble could be relieved, and complications guarded against, so as to assist nature in her efforts to throw off the disease. There was no panacea or specific remedy, but if the dependence of whooping-cough upon a *specific virus* be the true explanation of its pathogeny, the lines on which its rational treatment and prophylaxis were to be pursued became clearer and more hopeful."

It is my intention only to criticise the statement that "*the disease could not be controlled by treatment.*"

The importance of the isolation of all cases, of course, should not be overlooked. I fear that it is only recently, however, that people in general are awakening to the fact that it is not desirable, *even in summer*, to have their children exposed to whooping-cough! I have repeatedly heard people say, and they passed for very sensible people too, that "it was well for a child to be exposed to a *light form* of whooping-cough in summer, if they were healthy," rather than to run the risks of catching the disease in winter, or of having it later in life, when it might go very hard with them.

Such a statement seems highly absurd if it were not in reality a very dangerous opinion for a large class to believe in. We are all dependent on each other, and it behooves all good citizens to aid in the suppression of disease for the sake of others, as well as for their own sakes, in the community in which they live. Stricter laws should undoubtedly be made and enforced against all diseases, especially so against diseases of a highly contagious nature, like whooping-cough. Admitting the fact that whooping-cough in itself is "rarely fatal," the complications are very numerous, and thereby death results frequently. There are other complications which very much injure and weaken the patient in after life.

When we consider the infinite number of remedies, many of which are considered by their exponents to possess well-nigh specific powers, we would hesitate to add one more to the list; but it is very seldom indeed that one sees in any of the medical journals or text-books any reference to that most valuable remedy in whooping-cough, sulphate of quinine. I have not at hand Dr.

Dawson's (New York) reprint of an article, published, I believe, about five years ago on the "Treatment of Whooping-Cough by Small and Repeated Doses of Sulphate of Quinine;" neither can I remember the name of the journal in which it appeared. At this distance from "medical centres," it would take considerable time to find out. Dr. Dawson introduced this treatment from Germany, and first used it in the wards of the Hospital for Children in New York City, then under his care. He met with great success. I was fortunate enough to receive a copy of the article referred to, and employed this treatment with marked success in many cases in private practice. I was so much pleased with its workings and the almost *immediate relief* afforded to my *little sufferers*, and rapid destruction of the fungi which I believe to be peculiar to this disease, that I have used it and recommended it ever since. The treatment which I follow is to expose the patient as much as possible to the open air, and, if practicable, at our mountain or ocean resorts, and paying particular attention to food and clothing and general hygienic conditions is desirable. Every two hours I give a teaspoonful of a solution of sulphate of quinine four, six, eight, or even ten grains to the ounce. This remedy does not disappoint in many cases in *controlling the disease*, and if properly used, and with perseverance, in actually curing it, or at least shortening its course very decidedly. It seems to act as a destroyer of the fungi. It also nauseates and loosens the mucus in which they exist, and has also the valuable properties of a tonic. Unlike many of the other remedies which are so unsuccessfully exhibited in this disease, it has absolutely no injurious effects. The little patients begin to improve very shortly after the first two or three doses. I am fully convinced that a trial should always be made of the solution of sulphate of quinine in the strength and in the doses indicated, according to the age of the patient and the severity of the case; and after a few faithful experiments in this direction, no one will be able to say with truth that "the course of the disease could not be controlled by treatment."

THE KIND OF ELECTRICITY INDICATED.

BY W. O. STILLMAN, A. M., M. D.,
Of Saratoga Springs, N. Y.

The choice between the different kinds of electricity in individual cases is one which must have puzzled every practitioner in the beginning of his electrical practice. Doubtless electricians of wide experience have hesitated or pondered in their

own minds over many a case neither rare nor difficult.

The outlines of differential electrical therapeutics are becoming well recognized, and it is principally on minor points that differences exist in the theory and practice of electricians. For instance, I think it is generally admitted that in hemiplegia, "where there exists an exalted electro-muscular contractility, electricity, if used at all, should be used in the form of faradization, and with an exceedingly mild and rapidly interrupted current." When the reverse condition exists, and there is a marked diminution of the electro-muscular contractility, it is, perhaps, unanimously conceded that the galvanic current is the one needed. The same current is, by general consent, allowed to be the best, par excellence, for the reduction of tumors, for application to the central nervous system, for hyperæsthesia, for skin diseases, and inflammatory conditions when electricity is indicated.

From the latter law is evolved the "rule of thumb" that neuralgia is to be treated by the galvanic current "when firm pressure over the affected nerve increases the pain," and by the faradic when it does not. It is, perhaps, as good a rule as any, as a rule; and yet one would scarcely be ready to affirm that because the pain was not aggravated by pressure the galvanic current might not be the more efficient form in a given case.

By many it is claimed that the faradic current is the one indicated in the condition known as general debility or neurasthenia. This is the rule rather broadly laid down by Dr. A. D. Rockwell, in the *New York Medical Journal*, February 3, 1883. My experience has been that in many cases of this type the faradic current is contra-indicated. In a great many there is a nervous irritability associated with the exhaustion, which is increased and aggravated by the interrupted current. In many cases of neurasthenia there is hyperæsthesia of some cutaneous parts, or abnormalities of sensation. In almost all insomnia is conspicuous among the most annoying of the symptoms, while a large proportion suffer from a neurotic dyspepsia connected with a feeble stomach. These special symptoms, together with the muscular tremor and mental or volitional irregularities, have, in my experience, extending over some six thousand applications of electricity, (at Drs. Strong's, Saratoga Springs,) been more relieved and benefited by the galvanic current than by the faradic. While the latter current is almost magical in its alleviatory effects in a great number of cases, it should not be forgotten that there

is a large minority which are more benefited by the former, and that in some cases of general debility the faradic current may be positively contra-indicated. Routine practice, by "rule of thumb," may sometimes lead to distrust and disgust with the results obtained by means of electricity, as with other agents when following such dogmatic laws.

Another feature in connection with the use of galvanic electricity is its tonic virtues. These are too often lost sight of by practitioners, it would sometimes seem. This current appears to possess a power of harmlessly evolving nervous force, and then of seconding its action on the body. Many times the electrician seems to defeat his object by using too strong a current; and many of the best results which I have observed, in nearly all classes of cases, have come from decidedly weak currents.

ANOTHER EXPERIENCE IN THE REMOVAL OF TAPE WORM.

BY C. T. MELSHEIMER, M. D.
Of Bluffton, Ind.

In No 11 of the current volume of the REPORTER I noticed the article "An experience in the removal of tape worms," by Doctor Ward, which harmonized so much with my own that I adopted his advice in the treatment of these parasites. At the time, I had a case on hand which proved very refractory, and withal unsatisfactory in regard to the various noted remedies for its expulsion. The patient had been passing a segment or two of the worm almost daily, for several weeks, without any other annoyance than a pruritus ani whenever a link passed into the rectum, which ceased immediately on its expulsion. These segments were endowed with a high degree of vitality, so much so that life continued for ten or twelve hours after their expulsion. The separation appeared to depend more upon the act of spontaneity than from the action of medicine or any disturbed condition of the bowels; at least there was no more increase after the use of anthelmintics than passed with normal evacuations. I had made use of pretty much all of the vermicides, with the exception of turpentine, and while debating the propriety of giving it, I received the REPORTER and concluded to give Dr. Ward's recommendation a trial, inasmuch as the patient manifested a perfect abhorrence to the use of turpentine. I had considerable difficulty in procuring Dundas Dick & Co.'s capsules of extract male fern and kameela, and it was only after searching all the drug stores here, and most of those at Fort Wayne, that the article was found.

He was directed to abstain from food the evening before, and take a dose of castor oil. In the morning, as a poor substitute for breakfast, he was ordered seven or eight of the capsules, and a few hours afterwards some five or six more, to be followed by another dose of castor oil. The result of this treatment, which did not cover a period of more than twelve hours, was the entire expulsion of the remainder, representing a section twenty-two feet in length, and that, too, with very little constitutional disturbance. In this instance it proved to be tæniacide; the worm was expelled dead, softened and covered with a milky fluid (excretions no doubt), that contained thousands of ova. Tænia soleum is extremely rare in this section, but Tænia mediocanellata of Kuckenmeister is becoming more frequent, and the only reason that I can assign for this frequency is in the universal use of imperfectly cooked beef. I had under observation six cases during the last two years, and all of them occurred in subjects that were in the habit of using beef cooked extremely rare. In view of the host of testimony favoring this view of the origin of these disgusting parasites, it becomes a matter of great importance to all to have their animal food cooked to the extent of destroying all parasitic germs, and thus save the necessity of taking large quantities of drugs for their removal. In conclusion, I will add, but one out of the six presented symptoms of tape worm—the others were wholly unconscious of their existence until segments were passed with the fæces.

HOSPITAL REPORTS.

FACIAL NEURALGIA; THE BEST METHOD OF REACHING AND EXCISING THE INFRA-ORBITAL NERVE.—COXALGIA.—HYDROCELE; ITS RADICAL TREATMENT BY THE INJECTION OF TINCTURE OF IODINE.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL, JANUARY 6, 1883.

BY THOMAS G. MORTON, M. D.,

One of the attending surgeons to the Pennsylvania Hospital.

Reported by WILLIAM H. MORRISON, M. D.

GENTLEMEN: You have probably seen during the winter a number of cases of facial pain, or, as it is often termed, *tic douloureux*, a severe neuralgia involving the distribution of the infra-orbital branch of the fifth pair of nerves. The patient before you, a male, 32 years of age, came to the hospital six weeks ago suffering from this malady involving the left side of the face, which, on careful examination, was found to have its greatest intensity at the point of emergence on the face

of the infra-orbital nerve. Pressure over the region of the infra-orbital opening caused the most intense suffering. Tracing the area of pain from this point, it seemed to be entirely limited to the distribution of this nerve. The patient had occasionally, however, experienced shooting pains through the supra-orbital, and also through the inferior dental branches. This man, after five years of suffering, entered the hospital with the hope that some operation could be done for his relief.

The neuralgia originated, without assignable cause, five years ago. He had tried every form of treatment. When these cases come to the surgeon, it is usually found, as you see in this instance, that all of the teeth have been extracted on the affected side; for it is rather a common belief that these painful affections of the face are due to some irritation of the dental nerves.

After a neuralgia of this kind has lasted for so long a time, it is more difficult to control than if it had been seen at an earlier period; the associated nerves become more or less involved in the irritation, so that, after we have divided one branch of this complex nerve, we find the neuralgic condition has involved the other branches of the main trunk. It is also sometimes a matter of great difficulty to determine whether a neuralgia is induced by a central or peripheral lesion. The neuralgias are often induced or augmented by atmospheric influences; they are sometimes rheumatic or gouty in character, and sometimes they are unquestionably caused by malaria, and now and then due to syphilis; frequently the neuralgia is due to bony pressure upon the nerve trunk. This is more often the case when the neuralgia involves the inferior dental nerve, which, as you know, runs through the dental canal in the inferior maxillary bone, and is likely to be involved in the changes incident to advancing years, as atrophy and solidification of the bone, which often causes the nerve to be pressed upon. These changes in the bony canals are most apt to occur after the age of fifty or sixty; but as this patient is but thirty years old, there appears to be no reason why he should have such a condition in the course of the infra-orbital nerve.

The remedies employed in these instances of facial neuralgia are legion. Almost every form of drug has been used and lauded in particular cases. Electricity has been advocated, and in acute attacks, I believe that in such cases it is often of service. Local applications, as iodine, blisters, and the actual cautery, injections of morphia, etc., have been more or less of benefit in the treatment of these maladies. Frequently patients, after all the various forms of treatment have been tried, return with increased suffering. After other plans of treatment, which should be faithfully tried, have been exhausted, comes the time for considering the question of resection of the nerve. In the present case, the patient had, for five years, been treated by drugs, and his sufferings were so great that I did not think it worth while to adopt any internal medication, but advised an excision of the nerve, which I performed six weeks since.

I have brought the man before you to-day to show you two points—(1) the line of incision to reach the infra-orbital nerve, and (2) the method

of exposing the nerve to the greatest extent with the least disturbance of the osseous tissues.

The nerve emerges just below the infra-orbital edge. The root of the nerve passes underneath the eye, only separated from the eye-ball by the roof of the canal in which it lies. In excising the nerve, it is not sufficient to divide it at the point of emergence, for the disease is often located in or at the outlet of the canal, and I am never satisfied unless I cut the nerve at the posterior part of the orbit.

In order to reach the nerve without any needless destruction of bone (which is sometimes followed by necrosis), I make a curvilinear incision, from and half an inch below the external canthus, to the internal canthus, and then continue the incision to within a half-inch of the angle of the mouth. This flap can be readily thrown over, and there is then the greatest exposure of the infra-orbital opening. There may be some hemorrhage, but this is readily checked by pressure. The diverging filaments of the nerve are then to be looked for, and when gathered together readily demonstrate the location of the trunk of the nerve. This can be effected by using a blunt probe, or by a strabismus hook. The nerve filaments are put on the stretch, when the operator can see whether or not all the filaments have been included. The handle of the knife is then used to separate the tissue above the line of incision, and the bony edge of the orbit is brought into view; the roof of the orbital canal is then easily broken with a probe as far back as possible in the posterior portion of the orbit. The instrument which I devised for this purpose consists of a little hook placed at right-angle to the shaft of a probe, which after being carried under the nerve as it lies in the canal, can by a little effort thoroughly break up the thin bony roof, and so expose the nerve. After the nerve has thus been well elevated, a pair of blunt curved scissors are carried well back and the nerve is cut, traction is made on the filaments first exposed, the nerve being drawn out from the canal is again divided, so that at least an inch or more is excised.

The advantage of this operation is that the infra-orbital ridge is not injured, and deformity is thereby avoided. The only bony structure involved is the roof of the canal through which the nerve passes. This never gives rise to the slightest trouble. After the nerve has been excised, the tissues are replaced and secured by a few interrupted sutures.

The method commonly adopted to reach this nerve is by trephining the antrum of Highmore, breaking the floor of the canal, and removing the nerve in a manner similar to that which I have described.

Following section of a branch of the trifacial nerve, there is total anæsthesia extending over a certain area. After section of the infra-orbital, the anæsthesia involves almost a right-angled space. In this space the anæsthesia is absolute. If it is not so, doubtless some filament of the nerve has not been divided. The anæsthetized space extends over a region bounded by a line drawn from the external canthus to the angle of the mouth, thence to the middle line of the lip, along the median line of the nose to the internal canthus. In describing the absence of sensation

patients often say that the parts have "a wooden feeling." The mucous surface of the mouth and all the tissues supplied by this nerve are in the same insensitive condition. This want of sensitiveness may continue for an indefinite period, often several years; then a certain amount of return of sensibility may occur, from the inoculation or union of the divided trunk which sometimes takes place.

It has been said that after division of the infra- and supra-orbital nerves, changes are likely to occur in and about the eye, as conjunctivitis, ulcers of the cornea, eczema, herpes, and other troubles. I think that these occurrences are very exceptional, for I have divided these nerves a great many times, and have never seen any of these results.

Six weeks have elapsed since the operation. Previous to this, efforts at talking, swallowing, mental excitement, a draught of air, or the touch of a finger, would produce severe pain, with marked spasm of the muscles of the face, compelling him to close his eye, and contorting the face. The muscles of the brow and neck were also involved. The patient has taken no opium or anodyne for four weeks. He sleeps well, and is able to swallow, can talk and chew without any trouble. (The patient was now removed.)

I hope that the operation will prove a permanent success. I have seen many instances in which division of the nerve has been permanent; in others, it has relieved the pain for many months, and sometimes years; twinges of pain in some of the cases occasionally recurred, and gradually the old enemy returned, sometimes in a more frightful form than before.

Should the pain return, the patient can at least be relieved of terrible suffering for perhaps months or years, which is sufficient to compensate him for having undergone an operation, which can even be repeated.

Coxalgia.

There is a patient here I have not seen, but the resident tells me that he has some deformity of the hip. This boy I now present to you is 13 years of age. For eleven months he has had some trouble with his hip. I shall rapidly go over the case with you, and see what the trouble is. The patient attributes the commencement of the disease to being pushed down stairs. After the injury, he continued to run about for three months. He was then taken to a hospital, and kept in bed for three months. Since then he has been about on crutches.

This case gives me an opportunity of showing a condition to which I alluded at a previous lecture, when I stated that in inflammation of the hip-joint (a scrofulous disease, for all cases of hip-disease are of strumous origin), the nerve filaments surrounding and supplying the joint are more or less involved in the inflammation, and that the inflammation extends along the smaller nerves to the nerve trunk, which may be involved as far as the spinal cord. As a result we have sclerosis to a certain extent, and impairment of function. A certain amount of atrophy results. Here is an instance which will at once show you that this atrophy in a case of hip-joint disease has affected not only the muscles of the thigh and calf, but

that it has also extended to the bones. Variations in the length of the limb in hip disease are incident to other causes. Shortening may be due to changes which have taken place in the joint, head of the femur and acetabulum, as softening and absorption. There are changes here in the circumference of the limb, as well as in its length. The foot on the diseased side shows less development than the one of the sound side.

Inflammation of the hip joint comes on essentially as a synovitis of a strumous character. If the inflammation is very violent, abscess may rapidly form, the capsule be destroyed, and the pus passing into the muscular space cause violent irritation and inflammation; and the pus reaches the surface often by numerous tracts. These sinusses are often tortuous, extending far from the joint. As a result of the destructive inflammation and impaired circulation, there is often caries of the head of the femur; and if the diseased portions are not absorbed, they may separate as mortified or necrosed bone, and the fragments escape, enter the fistulous openings, or require to be removed by operation. In the earliest stages of hip disease, we find pain, swelling, and lameness. The effusion sometimes causes great distension, and if the fluid is not removed by the aspirator, the capsule may be ruptured, and the serum so thrown out into the cellular tissue cause cellulitis and abscess.

One of the earliest symptoms of this disease is rotundity of the hip. When we look for certain landmarks, we do not find them; in this case the ilio-femoral groove is entirely obliterated. There has probably occurred in this case destruction of the synovial membrane, ulceration has taken place, the head of the bone and the acetabulum have come in contact, and have united by adhesive inflammation. Almost every case of hip disease ends in more or less ankylosis. The treatment consists in absolute rest for the joint until all symptoms have disappeared, and frequently the child is put to bed and allowed to place the limb in the most comfortable position, which is that of flexion. He is allowed to lie in this way perhaps for months, until ankylosis has taken place, and the limb is immovably fixed in an angular position. The patient in walking is compelled to assume a bent posture, and eventually secondary curvature of the spine develops. This boy has been judiciously treated on the supposition that ankylosis would occur, the limb being kept in such a position as to be of the greatest service in walking, being ankylosed at a very slight angle.

I now get the boy to lie flat on the bed; if the ankylosis has taken place exactly on a line with the body, you will see that there will be no movement of the spine when I press both thighs firmly down; while if the diseased limb has ankylosed at an angle, however slight that angle may be, a curvature of the spine will occur on straightening the limb like the sound one, which is called an accommodative curve. As the boy lies on the table, with both limbs flexed or drawn up, the spine, you see, is in contact with the table, and I cannot carry my hand under the back. I now straighten the sound limb, and no amount of movement, flexion or extension that I make with the limb causes the least elevation or curve of the

spine. So soon, however, as I attempt to straighten the right leg, the spine raises, and to such an extent that I am able to carry my entire hand directly under the spine, which demonstrates the union between the femur and the pelvis at an angle. The exact angle of ankylosis can easily be determined by measuring the angle of the limb when the spine begins to leave the table.

After the subsidence of the active symptoms in hip-joint disease, which is treated by extension, the patient should be gotten out of bed, for confinement is always injurious to children. A certain amount of the head of the bone has been absorbed, and there is shortening. This should be compensated for by the use of a shoe with a high heel and sole, and an apparatus consisting of a steel bar passing along the outer side of the leg, having joints at the ankle and knee, but none at the hip, and secured to the body by means of a corset, and to the limb by straps. The patient can then go about securely. We cannot expect to remove the deformity which is incident to the disease. The diminished length and the lessened circumference cannot be overcome, but the limb may be made a useful one.

Suppose a patient had been allowed to lie in bed with the leg flexed, causing a right-angular deformity, which could not be overcome; the patient is etherized, and still with force the deformity cannot be removed (and the force should not be very great, for fear of fracturing the pelvis or femur). Subcutaneous osteotomy should be performed; this can best be done with Adams' saw. In order to reach the neck of the bone, the finger should be placed on the great trochanter, and directly beyond this is the neck of the bone. A puncture is then made with a narrow knife, which is carried on to the neck of the bone, and the capsule, if any exists, is divided, through which the saw is brought in contact with the neck of the bone. After the section if the limb is straightened and treated by extension with adhesive strips, like a case of fracture of the femur, union will quickly take place between the divided portions.

Hydrocele—Its Radical Treatment by the Injection of Tincture of Iodine.

Tumors of the scrotum are frequently met with. They may or may not involve the testicle. They may be connected with the abdomen. There may be a hernia descending into the scrotum, which may be forced into the abdominal cavity. Tumors affecting the scrotum may be syphilitic, tubercular, medullary.

One of the most common tumors of the scrotum is hydrocele—an accumulation of fluid in the tunica vag. testis. This can be diagnosed by the tenseness of the swelling, its pear shape, and especially by the readiness with which light is transmitted through it. This may be determined by examining the tumor in a dark room, or by holding a light to one side of the scrotum while it is looked at from the other side through the tube of a stethoscope. Hydrocele may be congenital or acquired. Where it is congenital, there is an accumulation of fluid from the abdominal cavity which has passed through the unclosed ring. By taking hold of the scrotum and making pressure, the fluid can often be forced out of it. The opening communicating with the abdominal cav-

ity is usually obliterated and the tunica vaginalis testis is formed. The effusion is the result of irritation of the membrane, which may be induced by strain, bruises, riding on horseback, stricture of the urethra, and other causes. The pressure of this large amount of fluid sometimes causes interference with the discharge or passage of urine. This man describes it as "a choking back of the water." The effusion may be enormous. I have removed two quarts. The largest amount on record is, I believe, some five or six quarts. This disease occurs generally before the age of two or three years, and more often after thirty-five or forty. It is especially common in old people. There are various forms of hydrocele, as hydrocele of the cord, encysted hydrocele, and double hydrocele.

To get rid of the effusion is the question: the hydrocele can be tapped and the liquid removed, but it will almost certainly re-accumulate. This is therefore called the palliative treatment. The radical treatment consists in exciting inflammation in the tunica vaginalis testis, the two surfaces of which come in contact after tapping. The inflammation is followed by adhesion of the two serous surfaces, and obliteration of the cavity. Whether a seton is used, or the scrotum slit open and packed, or carbolic acid or iodine injected—no matter what method is adopted, the object is to produce adhesive inflammation. The injection of iodine has long been a favorite method. I believe that the cause of failure which sometimes follows the iodine treatment may be attributed to the insufficient quantity of the remedy, or else to the fact that it is too dilute. At least $\frac{3}{4}$ jss. of the official tincture should be thrown into the sac and allowed to remain. This produces sufficient irritation and swelling of the scrotum, which we do not wish to control. A seton may be used for the same purpose, the only difficulty being that if it is left too long, it will produce suppurative inflammation, which is not desirable.

I shall now withdraw the fluid with a trocar. It is a good plan to attach to this form of canula a piece of rubber tubing. This enables you to remove the fluid without soiling the patient. It is hardly necessary to say that in introducing the trocar any large veins should be avoided. The fluid is now escaping. As you see, it is of a clear amber color, looking very like urine.

I find here a curious condition of affairs. The testicle on the left, or the hydrocele side, is of normal size, but the right testicle is only about the size of a lima bean, and is situated high up at the external ring. Considering the abnormal positions of the testicles, of which this is an example, reminds me of a case which I saw some time ago. A young man of about twenty came to me, stating that he had only one testicle. An examination showed but one testicle in the scrotum; the other was found about half an inch in front of the anus, was small in size, but could be moved only for a space of two inches in the perineal line.

It is always well, before using the iodine, after tapping a hydrocele, to get the patient to cough, in order to see if there is any evidence of hernia. There is nothing of the kind here. I therefore throw in two and a half drachms of tincture of iodine. The patient will now be put to bed, the scrotum to be well supported by a towel or bandage.

MEDICAL SOCIETIES.

PROCEEDINGS OF "THE COLLEGE OF PHYSICIANS OF PHILADELPHIA."

Sewer Gas, and its Alleged Causation of Typhoid Fever.

BY GEORGE HAMILTON, M. D.

[Read March 7, 1883.]

The subject of the paper now to be presented, is essentially similar to one read by the writer before the College in 1879, and reference to that paper will, from time to time, be made in regard to certain facts and statements therein contained. The opinion that sewer gas was, and continues to be, the principal cause of typhoid fever, and that all other causes combined are unequal to this single agent in the production of this disease, was opposed in that paper, as it will be in this. The views presented by Prof. Frank Hastings Hamilton, of New York, in a paper on "Sewer Gas," published in the *Popular Science Monthly* for November, 1882, are, essentially, those accepted by an immense majority, either in or out of the profession; and, on the other hand, they are either rejected, or not accepted, as a rule, by practitioners and writers who have had the most frequent and abundant opportunities for observing the origin, development, and progress of the disease. The important question, then, involved in this subject cannot be determined by mere numbers, but by an appeal to facts, not conjectural, because theoretical, but to such as are unrefuted, because insusceptible of refutation. The great and increasing importance, in a sanitary point of view, of several questions connected with this subject, may be regarded sufficient to justify the expression of opinions in opposition to those entertained by one so deservedly eminent in the profession as the author of the paper on sewer gas.

In support of the sewer-gas theory, Prof. Hamilton declares, "that the experience of every medical man, and of almost every intelligent citizen, is in accord." From an assertion in regard to medical men so sweeping as this, the writer cheerfully appeals to the page of medical history on this point; and the citizen must surely enjoy a rare degree of intelligence if he be capable of solving a problem in medicine that still remains *sub judice*. That the people in general have adopted the sewer-gas theory is beyond question; and the reasons for this are obvious. The efforts to gain over the public mind to this view have been, and continue to be, incessant; and these efforts have, in great measure, been made by physicians of enthusiastic temperament, but who, unfortunately, have had but limited opportunities to obtain a personal, practical knowledge of this subject. But what is still more important, mankind are in general strongly disposed to accept as true that which promises pleasure, profit, and more especially health, exemption from disease, and longevity. The latter have been freely promised, provided that the sewers, and the house connections therewith, be properly constructed and kept in good condition; the filth in the streets, and every other place where it is apt to be found, be carefully removed, and disinfectants properly applied. In

this way the stamping out of typhoid fever, scarlet fever, and diphtheria, was confidently predicted. Here, then, was the true balm of Gilead presented to view; and is it surprising that almost every one, even the incredulous, should banish the dread that had so long held them in doubt and apprehension, and turn with wistful and confiding looks towards, and gladly accept, the proffered boon?—when, too, all this was to be had by the mere expenditure of the requisite money for a certain amount of mechanical and other labor.

A most discouraging thing, in this connection, is found in the assertion by Prof. Hamilton and others, that even when no sewer gas or offensive odor can be perceived, the gas with its fatal germs may yet pervade the residence of an occupant, whilst he is ignorant of any method of finding out whether or not such germs infest his home. This asserted fact is perhaps the key-note to the proposition, that all the ordinary or extraordinary and costly appliances now in use, and generally regarded, when kept in order, as capable of excluding sewer gas from dwellings, should be thrown aside, and that other apparatus should be erected in a detached structure, outside of the mansion. This proposition, emanating from a few sanitary engineers, is well-nigh impracticable. The plan has been tried in only a few cases, but not long enough to establish its supposed superiority. Colonel Geo. B. Waring is quoted in the paper of Prof. Hamilton as saying, "that such plumbing work as is to be found in nine out of every ten houses, even in Fifth avenue, is unsafe;" what then must be the condition of ordinary houses, constituting the vast majority, in view of the limited pecuniary resources of their occupants? Sanitary Engineer C. F. Wingate is quoted to this effect, that the constant demand for the doctor's services in so many houses in their normal bad state, and the fact that his services are no longer demanded when they have been put in sanitary condition, tells its own lesson. A lesson to have value, the doctor forgets, must not be based upon assumed premises. From this quotation it does not appear that the apparatus was other than what is now in general use, but that it had "been put into sanitary condition," and in this he is in accord with a large majority of medical men and sanitarians. Dr. Barker, in his contribution to the paper on sewer gas seems to deplore the fact "that of two young men, who suffered from typhoid fever, one died, and upon examination it was found that there was not a trap in the whole building!" But if the opinion of sanitarian Waring, and others who coincide with him, be correct, the mere existence of such apparatus within the walls of a building serves, nine times out of ten, rather to increase than diminish the danger! The actual causation of disease, in general, is among the most obscure of medical problems; and in regard to the sickness of the Prince of Wales cited by Prof. Hamilton, and also that in the National Hotel at Washington, or that occurring during the Centennial Fair, medical opinions are not at all in accord. Prof. Hamilton says "that plumbers suffer frequently;" but it has never yet been proven that they suffer more than others, although they are exposed to the action of sewer gas in its most concentrated form; and the reason why they do not suffer more, he

informs us, is "that they are in most cases in the full vigor of adult life and health." The reason here assigned will, the writer is satisfied, surprise every physician who has had an extensive experience in typhoid fever, or who is familiar with the written history of this disease. From early manhood, or womanhood, until the thirty-fifth year, is the admitted period of by far the largest number of attacks; and this holds good in several other acute maladies, notably in bilious remittent fever. In regard to this disease the late Dr. Parish, eminent as a citizen and a most experienced and practical physician, said to his class of students, "that if any of them became country practitioners they would find bilious remittent very prevalent and fatal as compared with the city;" and, with emotion, referred to his numerous consultations with country physicians within a radius of seven miles from Philadelphia, on either side of the Delaware, where he often witnessed the robust farmer, or his stalwart sons, sinking away into death, despite the efforts of the physicians. Now that this form of disease is supplanted by the typhoid, a similar condition obtains, as may be seen when the writer states that four cases of intestinal perforation occurred to him in the space of twelve months, whilst practicing in the country, thirty miles from Philadelphia. But more upon this point hereafter. Prof. Hamilton also speaks of the "immunity which adults usually enjoy, and especially those who are most of the time away from home and in the open air."

On the contrary, in his country practice, the writer nearly always found that the young men who were away from their residence, at work in the fields, were more frequently attacked with typhoid fever than the females, who were generally engaged in domestic duties in or about the house; and if, as the sanitarians declare, "that there is in the country houses, or the surroundings, something equivalent to sewer gas," why is it that the reverse, as to sex, should not be the case? Diphtheria is also said to be caused in great measure by sewer gas: why is it, then, that the most violent and fatal attacks of this malady occur in the country, sweeping off at times four, five, or six children, in a single family, without a thought of sewer gas; whilst in cities, with sewer gas almost everywhere, the proportionate mortality is much less? Notwithstanding the testimony of Dr. Alfred Carpenter, of London, as quoted by the author of "Sewer Gas," to show the causation of scarlatina by this agent, here again such testimony is confronted by facts similar to those adduced in regard to diphtheria. It is only a few months since scarlet fever appeared in a town in Pennsylvania, noted for its cleanliness, and occasioned a proportionate degree of mortality unknown in Philadelphia. We now come to a singular and very important statement in the paper on "Sewer Gas," namely, "that in Asiatic cities, where modern improvements in plumbing are unknown, typhoid fever, diphtheria, and scarlet fever are seldom seen; whilst with us they have increased, as some declare, just in proportion to the extension of these improvements."

After this comes the admission of Dr. O. C. DeWolf, Commissioner of Health for Chicago, "that water-traps, as at present constructed, do not pre-

vent the passage of disease-germs into our houses." Dr. Andrews is quoted by Prof. Hamilton essentially as follows: "Canton is a city of bad smells, it has no water-closets or connection with sewers, and its *unsanitary* condition is unquestionable; yet there is rarely any typhoid fever or diphtheria;" and he expresses his belief, "that water-closets tend to propagate these diseases, instead of preventing them." Prof. Hamilton declares "that the several classes of professional experts seem to have lost confidence in each other, and are heard constantly charging one another with incapacity." The chemists apparently are not agreed, the plumbers are charged with incompetency, and they, in turn, regard the physicians as their "most wrong-headed customers," possessing only a "dangerous smattering" of knowledge upon this subject. An architect has complained "that men of his calling have been blackguarded, lectured, and blamed by eminent doctors for their supposed ignorance of matters of this sort;" and a sanitary engineer has said publicly, "that there was probably only one architect in the city competent to execute the specifications for the plumbing of large houses;" while a distinguished member of the National Board of Health said publicly, "that he could count upon his five fingers all the sanitary engineers in this country in whom he could place any degree of confidence." If only the half of what has just been said be true, how embarrassing must be the condition of the public, and how greatly will be augmented the alarm, already so unnecessarily excited; and, in view of what has now been stated, may it not be thought that the motives thereto have not always been of a benevolent and purely unselfish character?

It is now time to confront the popular opinion that typhoid fever, diphtheria, and scarlet fever are caused by sewer gas, and that to a degree unequaled by all other alleged causes combined. In attempting to do this, such cases as the following will be completely ignored: Mr. A., on returning from his summer tour, perceived, distinctly, the smell of sewer gas in his house, and fell sick on the third day with typhoid fever. What can be said against sewer gas in this case, it may be asked? In answer, it may be said, that while, by a bare possibility, the gas was the cause of the disease, the probabilities are all the other way. In the first place, the period of incubation is from eight to twelve days; in the second place, the writer's experience has convinced him that in not more than one house out of five has any smell or sign of sewer gas been detected, either before or during an attack of typhoid fever. And again, if the opinion lately advanced by a few of the most eminent authorities, that, as at present constructed and placed within the dwelling, the apparatus is incapable of excluding the gas, is correct, then, in such a city as Philadelphia or New York, many thousands more must be added to the tens of thousands of houses said long ago by the alarmists to be infected with sewer gas. In this connection, it may further be stated, that if the dwellings of this city and those of New York are infected to the extent asserted, then the conclusion is inevitable that the mortality would be absolutely frightful; and yet, in some weeks, in our city and in New York, with, taken

together, about three millions of people, the deaths have been down to two, three, or four; while diphtheria, caused, as sanitarians and inexperienced physicians say, by the same sewer gas, has at this identical time occasioned weekly, the death of about thirty or forty persons. In the third place, it is well known that many individuals on returning from the country to their homes in the city, in a very few days, before the period of incubation has expired, have had attacks of typhoid fever; and such cases may fairly be regarded as having had their origin in the country.

Another instance of typhoid fever is this: A complaint was made to the Board of Health that a stagnant pond upon the outskirts of the city had already caused two persons to fall sick with fever. The pond was, by order, filled up; the patients recovered, and no others were attacked! Could anything, many would ask, be clearer than the exciting cause of these attacks? That a vast majority would regard the cause assigned as the true one need not be doubted; but it is not to be forgotten, that a large majority of people are by nature credulous, and, as a rule, the credulous are not logical, and the faith of such persons, as Goethe and Richter have said, is a matter of feeling, affection, aversion, rather than of reason, as the following example in relation to that just quoted, may serve to illustrate. Into the family of a wealthy farmer, a few miles distant from the ill-conditioned pond alluded to, typhoid fever entered at about the same time as in the former case; several of the members were attacked, and, as in the former instance, all recovered. There was no stagnant pond here to complain of; on the contrary, the farm lay in a beautiful elevated section of the country, was in all respects a model farm, the agriculture, domestic, and general economy exceptionally good; yet all this, as the writer had often seen in his rural practice, occurred without the agency of sewer gas or (apparently) any other one of the agents so commonly held responsible for these attacks.

The writer is well aware that the points maintained in opposition to the current views as to the origin of typhoid fever are not accepted by a very large proportion of medical men and sanitarians; but it should be remembered, that by the reports of the Board of Health of Philadelphia, there have been on an average weekly, for the last ten or twelve years, but seven to eight deaths; hence, it is evident that, with all the alarm in regard to typhoid fever, there has not been opportunity for one-half of the regular physicians of this city to become fully acquainted with the disease, in its various forms and aspects. In every instance, however, when the writer has inquired of any one who had practiced extensively, both in town and country, the answer has been nearly always, that the disease, when it appears in the country, is infinitely more prevalent and fatal than in the city, and that, as a rule, it was impossible to discover whence it originated. But, on this point, let us turn to an eminent authority—Trousseau, that great medical light of the nineteenth century. After speaking of the great difficulty of discovering the intimate causation of disease in general, and of the great advantages of the practitioner in rural districts in regard to this point, he declares,

"that the ordinary causes given in explanation of the origin of typhoid fever are trivial (*banal*), and deserve no serious consideration."

(*To be continued.*)

THE KENTUCKY STATE MEDICAL SOCIETY.

The Society convened in regular session at 12 m., Wednesday, April 4, at Masonic Temple, in Louisville.

The regular order of business having been disposed of, Dr. T. B. Greenley, of Jefferson county, made the report on the progress of therapeutics. He referred to the extensive use being made of iodine and iodide of potash, as well as carbolic acid, in the treatment of typhoid and malarial fevers, but failed to report original observations on the subject. His experience in the treatment of intermittents is favorable to the further trial of the sulphites and hypophosphites. Borax in epilepsy he recommends when the bromides fail. Atropine and ammonium bromide have likewise served in his experience as useful remedies in the treatment of spasmodic affections. The treatment of vomiting by the use of water as hot as can be borne he refers to as an old treatment resurrected to subserve a useful purpose. The *Prunifolium Virginicum* has maintained the reputation it acquired upon its advent into professional favor as applicable to threatened abortion. The ether spray in facial neuralgia was recommended, but whether as a palliative or curative agent the author failed to mention. *Eucalyptus globulus* has failed to meet the expectations indulged by those who anticipated in its use a valuable substitute for the preparations of Peruvian bark. *Pinus Canadensis* for chronic diarrhœa and inflammations of the urinary passages; dugong oil, as a substitute for cod-liver oil; calcium chloride in glandular enlargements, has each been productive of good results in the author's hands. The writer referred to the changes made in the quantities of active ingredients in the standard preparations in the new pharmacopœia and wisely cautioned that care be exercised in designating the quantities of them when ordering them in prescriptions.

In the discussion which followed, Dr. Preston B. Scott, of Louisville, called attention to the fact that one advance in the preparation of medicines had been overlooked by the author of the report on therapeutics, and he therefore exhibited for inspection the compressed tablets as illustrating one of the elegant and reliable forms of administering the various alkaloids in practice. In their porosity, and therefore ready solubility, Dr. Scott finds qualities that recommend them to the attention of the profession.

Dr. W. M. Fuqua, as chairman of the section, delivered an address on surgery. Wound treatment first engaged the writer's attention. Under this head reference was made to antiseptics, as practiced by applications such as carbolic acid and iodoform. The speaker deprecated the almost universal use of iodoform, for the reason that absorption of the drug has been followed by unpleasant mental symptoms, showing the poisonous effects of the drug when absorbed. Drainage received fit consideration in this connection. The field of micro-organisms was hastily scanned, and

the lessons of the first discoveries in this field applied to those of later dates, and the influence upon future investigations foreshadowed. The germ theory as applied to typhoid, malarial, and scarlet fever, finds in the author a firm believer, and forcible, if not eloquent, exponent.

Peritoneal surgery, the author says, has grown with the growth of the antiseptic system. In the treatment of wounds, surgical or accidental, involving the peritoneal cavity, Sims voices the most recent utterances when he declares that unfavorable terminations are the result of septicæmia and not peritonitis, and that this septicæmia is due to effusions into the peritoneal cavity.

Resection of the pyloric extremity of the stomach has been performed perhaps fifteen times. Three thus operated upon are still alive. The probabilities are that the operation will never be recognized as a justifiable procedure. Operative procedures for the relief of intestinal obstruction, colotomy, rupture, and gunshot wounds of the bladder, hernia, and operations upon the chest and lungs, were each in turn considered, but beyond a reference to the subjects, nothing of importance can be said to have been developed.

In gynecology, the greatest advances have been made by native talent. Operative measures for the relief of epilepsy, as recently shown by Dr. Alexander, is likely to be productive of benefit, and will shortly, in the estimation of the author, become of recognized utility. Shock, that peculiar and often fatal condition incident to grave surgical operations and injuries, was not clearly understood until of late years.

Discussion on this paper was confined to a consideration of the subject of antiseptics, and particularly the dangers attendant upon the use of iodoform.

Dr. J. M. Matthews, of Louisville, said: "I have been highly edified by the paper of the distinguished surgeon. There was one point that impressed me from the beginning, and I wish to call attention to it in order to elicit a discussion from the Society with reference to the point.

"The author mentions that the ideal antiseptic has not yet been discovered; and in making this assertion he speaks of iodoform in disparaging terms, because of the danger attending its absorption. In a special way I have used this agent for a number of years, and notwithstanding the fact I have seen daily in medical journals and heard it spoken of freely as being dangerous, I have used it to its full effects, it seems to me, without once having reason to think that by its application I had done the patient harm. In treating diseases of the rectum, I have used it freely, packing an ulceration with it as many as three or four times a week, and continuing this for three or four weeks, until a healthy action had been excited, and I have yet to meet a single subject wherein any deleterious or dangerous symptoms followed as a consequence of its use. Applied as it is in my practice, where you can watch its effects and see the granulations springing up, after several years of experience with it, I must say I have failed to see a single instance in which it has proven deleterious so far as the absorption of the drug has affected the constitution of the patient. As to its local effect, I think no surgeon can have a doubt as to its excellence."

Dr. D. W. Yandell, of Louisville, said: "The point raised by Dr. Matthews is one of importance. As I gather from the discussion, what the chairman of the committee has said touching the dangers of iodoform does not apply to its application to the small surface to which it must be applied in diseases of the rectum, but to the absorption of the substance when used in enormous quantities. I do not infer that iodoform used upon small ulcerating surfaces could be accompanied by any danger. I wish to confirm in my own experience the value of iodoform in rectal troubles. I have found it of especial use in the treatment of hemorrhoids after treatment for removal by any of the usual methods. In some cases there is a good deal of active inflammation left, in others a sluggish condition of the parts, a calloused-edged ulcer, or much infiltration in the adjacent tissues; under these circumstances, but more particularly in the acute ulceration that follows, I have almost invariably gotten excellent results from iodoform. I quite concur in the remarks of Dr. Matthews touching its harmlessness. I have never known a patient to complain of it, nor, in fact, any ill from it at all. I think it has been much overrated, because it has been used in too many things. Like Martin's bandage, the only trouble with it is that it does too much, and too much is therefore expected of it. I am sure that in many forms of ulcerations, and particularly in those forms about the rectum, it is a valuable addition to our surgical remedies."

Dr. D. S. Reynolds, of Louisville, while "quite agreeing with the gentlemen with reference to the importance of the use of antiseptics, recognizes a great difficulty in the want of a selection of the proper kinds of antiseptics for particular conditions. Thus the chloride of sodium is an efficient antiseptic in acute purulent inflammations of the mucous membranes, whilst boracic acid is applied with better results to those of a chronic form. Thymol and eucalyptol are of like benefit in the treatment of those inflammations which become septic by becoming purulent, as in the cavity of the middle ear, the tear passages, and other similar states. The aspergillus albicans which invades the external ear is destroyed, perhaps, more readily by eucalyptol and thymol than by other agents, though boracic acid is not to be neglected in fungoid growths of this character. The tinea tonsurans and trichophyton, which sometimes invade the hair follicles along the margins of the lids, are quickly destroyed by boric acid. Thus I imagine that when we are able to classify the germs in a given instance that are giving rise to pathological processes, we shall then be able to arrive at some definite conclusion as to the selection of the germicide applicable and capable of their destruction."

Dr. Holloway, of Louisville, thought it would be better to classify these remedies as germicides rather than as disinfectants or antiseptics. So far as iodoform is concerned, he looked upon its action as simply alternative; the same is true of the local action of carbolic acid.

In speaking further of the subject, Dr. Fuqua related two cases that came under his own observation, in which the persistent use of iodoform resulted in mental derangements to such an extent as to make it necessary to withdraw it.

Dr. Holloway suggested that the internes at the City Hospital be heard from on the subject. Dr. Sargent accordingly replied that during his term of service iodoform had been used according to Col. Sellar's directions for the use of his eye-water; that in the venereal wards it had received the designation of the ward cologne, and so far as his observation had extended it had produced no troublesome constitutional effects.

After all the discussion elicited, Dr. D. W. Yandell, of Louisville, concluded that in those cases in which the use of the drug was followed by unpleasant manifestations, they arose from some idiosyncrasy of the patient, as is sometimes exhibited in the intolerance of morphia by certain individuals.

The nominating committee was then announced, and the society adjourned to meet

THURSDAY MORNING

at 9 o'clock. The first paper read at this session was a report of the committee on Medical Ethics, by Dr. F. J. Yager, of Campbellsburg.

Dr. Preston B. Scott, of Louisville, read a paper on the subject of Disorders of the Menstrual Function. Many young women, said the writer, suffer from dysmenorrhœa, and in fact, the functional disorders of menstruation have steadily increased. Pain, scanty and irregular monthly flow, are the commanding features. Conditions which impair nutrition and depress nerve force are the leading causes. The results are recurrent suffering, sympathetic disorders, reflex disturbances, and in due time local changes. In view of future married life, Emmet's tables show how large here is the field of preventive medicine. It is to this class of sufferers, and it is a very large one, I call your attention.

To-day two young ladies, sisters, aged 19 and 21, came into my office looking the pictures of blooming health. One had only a scanty flow, followed by severe frontal neuralgia after every monthly period. The other went to bed with fearful cramps for two days. They had been suffering thus for two years, and for the first time now had come to seek medical advice.

Now Emmett has given us some valuable statistics, showing how much the health and capabilities of woman have been influenced by disorders of early menstruation. I asked a young society lady not long since how many of her friends suffered as she did. She answered, "Nearly all of them suffered some, many of them enough to go to bed."

These conditions, the author argued, were due to the mode of life of women and girls at the present time. He cited the fact that it is no uncommon thing for as many as eighty girls and women to be seated in one room, sewing in dress-making establishments in this city. Many others labor in factories from seven in the morning till six in the evening, in defiance of an undeveloped and overstrained function struggling into healthful regularity.

The author gave some attention to the deleterious effects of the forcing plans of education prevalent in this rapid age.

With respect to treatment, it must ever be borne in mind that this function is a monthly cycle of nerve force, intensifying as it reaches its matura-

tion, with a climax in a flow of blood and mucus, healthful and complete as it is painless and uninterrupted. To reach this end, he directs his treatment to a period of apparent rest, a period of approach, and the period of actual flow. One of the chief difficulties the author has met has been to have patients to keep their count, and have a due regard to the circumstances of their living, in so far as that influences the course of the flow. In the intervals their pain is forgotten, and hence as a class they are fastidious in regard to the taste of their medicines. Arsenic, strychnia, iron in the form of lemonade, as recommended by Goodell, all serve a useful purpose when given with due respect to time and circumstance and indication. At the approach it will be found necessary to resort sometimes to sedatives, sometimes to stimulants; for the latter purpose, the hydropiper and the fluid extract of cotton root has given satisfaction; for the former the pulsatilla ammonii has stood the test of six years' constant application. The principal chance in all cases, however, is to use the interval of repose in restoring to a proper balance the depressed nerve force. Medicines alone will often fail.

Dr. Joseph McCormack, of Bowling Green, next read a paper on the subject of Hygiene in which he took occasion to dwell at length on the duties and powers of Health Boards in various sections of the country, and to compare to some extent the work and condition of the Kentucky State Board with those of other states.

This, with the spirited attacks that have recently appeared against the Kentucky State Board of Health in the local press as well as in the medical journals of distant cities was the signal for a spirited discussion of the subject, participated in by Drs. Larrabee, Holland, Yandell, D. W. Pinkney, Thompson and McCormack.

Dr. Larrabee remarked upon the difficulty of such Boards of Health to accomplish any useful purpose, in the present state of apathy of the people.

Dr. Holland, after speaking of the value of agitation as a means of instructing the people concerning the matters in which instruction is desirable, said: "As a sanitary official I am aware that the county Boards are taking more interest in the matter and in their duties than they ever have before. The people are awakening; the doctors are awakening. This is good. You can estimate very correctly the amount of public spirit, the genuineness of the heart and the soundness of the head of a doctor, by his growing faith and activity in sanitary work." Dr. Holland referred to the attacks in the local medical press concerning the inefficiency of the Board and its small accomplishments, and pointed with pride to the change of public sentiment at the time the Board was created, and in conclusion appealed to the profession to uphold and succor a sanitary movement when it is thus once started, cheer it when it recovers from a momentary fall, and for God's sake to let the movement go on.

Dr. Pinkney Thompson, President of the Board, arose, not to defend the State Board of Health, but with the hope that he might say something to encourage a spirit upon the part of the members to correct the erroneous statements made by Dr. Yandell. To begin with, it would appear that

just such speeches as he has made, and just such articles as he chooses to publish, have been made and written against every public health organization. The State Board of Health of Michigan nor even that of Massachusetts, has escaped this and even worse criticism. By the same spirit as that here manifested, the National Board of Health has been completely crushed out.
(*To be continued.*)

TRANSACTIONS OF THE NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

Meeting of February 23, 1883. President J. T. Eskridge in the chair.

Dr. Rebecca Hunt read an account of an operation performed for the relief of imperforate rectum. The existence of hypospadias in the case possessed an important embryological bearing.

Discussion of case reported by Dr. Longaker (see page 396).

Prof. J. B. Walker, mentioning the frequency with which carcinoma of stomach occurs unaccompanied with severe symptoms, reported an instance of a male who had a large malignant tumor of the pylorus, and no especial symptoms until the last five weeks of life. These, however, were not those of cancer, but typically asthenia.

CASE 2. Large, strong, vigorous man suffered with an apparently causeless vomiting. Emesis occurred at long intervals. Fatigue and excitement seemed to develop the tendency to vomit. Anorexia existed, but no other symptom that would lead to a suspicion of so serious a disease as carcinoma. Anæmia was noticeable. A regurgitant mitral lesion was present, and the above manifestations of disease were attributed to it. The cachexia of carcinoma is peculiar, and is not properly described by the term icteroid. It is a peculiar silvery hue, and the epidermis presents a tessellated and micaceous appearance clearly shown when light is directed obliquely upon the surface. It was solely from this peculiar condition of the skin and its location upon the dorsum of hands that carcinoma of stomach was diagnosed. There was absence of local tenderness, hæmatemesis, and constipation. No epigastric tumor, but alone the peculiar silvery cachexia that was made the basis of diagnosis. Four weeks before death œdema of ankles for the first time presented.

In Case 3, a patient suffered from occasional vomiting. No other symptoms pointing to serious organic disease existed, except this peculiar silvery condition of the skin.

Carcinoma of stomach was diagnosed, and the autopsy revealed extensive carcinomatous degeneration occupying the lesser curvature.

CASE 4. Another instance in which this peculiar silvery cachexia alone existed. Autopsy revealed correctness of diagnosis.

CASE 5. Silvery cachexia. Death. Autopsy disclosed in addition to gastric carcinoma, infiltration or involvement of a portion of the liver.

In concluding, Prof. Walker stated that this peculiar cachexia is not so noticeable upon the face, but is especially conspicuous upon the dorsum of the hands, the thorax, and abdomen.

Dr. L. Brewer Hall discoursed upon the import-

ance of microscopical examination of these malignant cases. Many cases are indiscriminately termed scirrhus, when such examination reveals the characteristics of some other type. In order to clearly know the specific course and symptomatology of the several varieties of carcinoma, it is necessary to carefully study each specimen, and by coupling the histological characteristics with the clinical phenomena, we will be enabled to understand the types with which we deal.

The specimen was referred to the committee on pathology.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The regular monthly meeting of the College was held on Wednesday evening, April 4, 1883.

After the transaction of routine business, Dr. J. T. Eskridge read a most elaborate and carefully prepared paper on a case which he called "Tubercular Cerebro-Spinal Meningitis of eight months' duration." Drs. Roberts Bartholow, and Da Costa, and President Stillé, took part in the discussion which followed, and raised doubts concerning the correctness of the diagnosis, Dr. Da Costa insinuating that it was rather a case of spurious cerebral meningitis.

Dr. J. Solis Cohen followed with a statistical paper, in which he held that experience proved that laryngectomy did not have a tendency to prolong life, and stated his preference for tracheotomy.

Dr. S. W. Gross differed with him, and mentioned several cases not referred to by Dr. C., where laryngectomy had produced very satisfactory results.

Dr. Win. Barton Hopkins read the last paper of the evening, and exhibited a woman upon whom Dr. John Rhea Barton had performed excision of a large piece of the shaft of the radius in 1828.

These papers will appear in full in future issues.

Feline Test for Defective Sewer Pipes.

Cats have a great fondness for the odor of valerian. So an ingenious Boston woman, suspecting some defective pipes, borrowed two cats and shut them up in the suspected room; then, having purchased some oil of valerian, poured it into the highest basin in the house, and proceeded down stairs to watch the result. She was gratified to find both manifesting a preference for a certain spot in a closet near which a waste-pipe ran; and here, on further inspection, a complete separation of the pipe was discovered.

A Modern Miracle.

The *New Orleans Picayune* says that a medical man in New Orleans, who is fond of his little joke, called on a colored minister, and began to catechise him. "Why is it," said he, "that you are not able to do the miracles that the apostles did? They were protected against all poisons and all kinds of perils. How is it that you are not protected now in the same way?" The colored preacher responded promptly: "Don't know about that, doctor. I s'pect I is. I've taken a mighty sight of strong medicine from you, doctor, and I is alive yet."

EDITORIAL DEPARTMENT.

PERISCOPE.

Ichthyol in Skin Diseases.

The New York Medical Journal, March 17, 1883, says:

In a late number (December, 1882,) of the *Monatshefte für praktische Dermatologie* are two contributions—one by Rudolf Schröter, the other by Unna—relating to a new remedy for skin diseases. The article by Schröter relates the history of its discovery and describes the method of its preparation, while Unna gives an account of how it is employed and of its effects upon diseases of the skin.

Ichthyol is an oily product obtained from a peculiar bituminous mineral found in the region of Seefeld, in the Tyrol. The mineral occurs in beds or veins of varying thickness, lying in fossiliferous rock, which bears numerous fish-prints, together with a certain number of petrified fishes. It has been surmised that the bitumen owed its origin to the animal residue of fishes and other marine animals left there in prehistoric times, when the region was still submerged by the sea. Hence the name "ichthyol." To obtain the oil, the bituminous rock is first subjected to a dry distillation in iron retorts. The fluid product that results soon separates spontaneously into a thick, tarry substance, and a very fluid, dark-colored, strong-smelling oil. The latter is then subjected to the action of concentrated sulphuric acid, and various other chemical processes, by means of which it is clarified and refined, when a neutral or slightly alkaline product results, having a peculiar odor described as "kräuterartig" (herb-like). The product, which is what is known as ichthyol, is regarded as an extract from the original oil. Its chief ingredient is said to be a sulphur acid. Sulphur forms from two and a half to ten per cent. (according to the method of preparation) of its composition. In appearance it is of a somewhat tarry character, but resembles none of the ordinary tars either in its odor or in its chemical composition. Its consistency is about the same as that of vaseline. It forms an emulsion with water, and is miscible in any proportions with oils or vaseline. It is partly soluble in alcohol and partly in ether; wholly so in a mixture of both.

Unna maintains that the efficacy of ichthyol as a topical agent in skin disease—and this efficacy he has found to be very considerable—is chiefly due to the sulphur which it contains. He regards the drug as essentially an artificial production, and refers to the fact that the chemical treatment by which it is produced increases the proportion of sulphur from two or three per cent. to about ten per cent. Moreover, there is a marked increase by this same means in the proportion of oxygen. He considers ichthyol as resembling a ten per cent. sulphur ointment, but differing from the latter in that the sulphur is in a very intimate chemical union with the other ingredients.

Unna made his first trial of the drug in a case

of universal psoriasis. One arm was treated with chrysarobin, the other with ichthyol. At first the latter appeared to be having the most rapid effect, but afterward, when the chrysarobin had fairly begun to act, the ichthyol was shown to be so decidedly inferior that it was abandoned entirely, and the chrysarobin was applied to both sides. But it was discovered that ichthyol, though applied for a long time continuously, even in its purity, to the skin, never caused any signs of eczema, as would invariably be the case were a ten per cent. sulphur ointment applied in the same way. This led to the employment of the new remedy in eczema. Unna refers to thirty cases that he has treated with ichthyol with very decided success. The eczemas treated were of many varieties—both moist and dry, papular, squamous, circumscribed, and diffuse—and were confined to no particular region of the body. The drug was employed in the form of a salve, varying in strength from five to ten, fifteen, and twenty per cent.; also it was used pure or in the form of spray from a solution in alcohol and ether. The pure form is not recommended, however, but a fifty or forty per cent. solution in vaseline or lard is preferred for adults, while from ten to two per cent. is considered strong enough for children.

It is advised that, commencing with an ointment moderately strong, the strength be gradually decreased as the case improves, since otherwise the ointment, after a time, tends to retard the progress of the cure. Moreover, the condition of the cuticle is said to form a criterion for the strength of the application. For example: If in a papular eczema a fifty-per-cent. ichthyol salve answers the purpose, in a moist, abraded eczema a strength of not over twenty or thirty per cent. will be required. In general, the more intact and the thicker the cuticle, the stronger must be the ointment. The chief merits of ichthyol are stated to be as follows:

First, it tends largely to relieve smarting and itching, combining the good qualities of both Hebra's (diachylon) and Wilson's (zinc oxide) ointments on the one hand, and those of carbolic acid and tar on the other.

Second, it offers this advantage over all other sulphur preparations, namely: that it may be combined with lead and mercurials without any separation of sulphur taking place.

The following combination is recommended:

R. Lithargyri,	10.
Coq. c. aceti,	30.
Adde	
Olei olivæ, adipis, āā,	10.
Ichthyol,	10.
M., ft. ung.	

Inasmuch as this ointment forms an emulsion with water, it is very easily removed from the skin. The disagreeable odor of the ichthyol has not yet been overcome.

Aside from eczema, Unna is of the opinion that

the new remedy will be found valuable in all cases where sulphur preparations have heretofore proved themselves valuable. With reference to the internal exhibition of ichthyol, there have been as yet no satisfactory investigations.

Non-Puerperal Uterine Hemorrhage.

Dr. Paul F. Mundé contributes a very practical paper on this subject to the *Medical Record*, February 10, 1883. He describes a condition in which there is either a continued discharge of blood, or where the menstrual flow lasts unusually long and is abnormally profuse. The following are the causes:

1. Non-puerperal erosion of the cervix uteri; due to the irritating discharges of the almost ever-present cervical catarrh, or friction of the cervix against the posterior vaginal wall. For this condition he applies a solution of nitrate of silver (3j.-3j.) within the cervical canal and over the eroded spot. A thin dust of finely powdered iodoform is then blown on the cervix through an insufflator, a tampon soaked in glycerite of tannin, equal parts, placed against it, a dry pledget over this, and the speculum is withdrawn. These tampons are to be worn for thirty-six to forty-eight hours, and an injection of tepid water, with one or two drachms of sulpho-carbolated zinc or plain sulphate of zinc should be used twice a day for three days, when the patient should again present herself for local treatment. The same application will probably be repeated every three days, until the erosion shows signs of healing, when a milder solution of nitrate of silver (3ss. or grs. xx. per ounce) should be used; or the absence of improvement calls for a change of treatment. In very obstinate cases, with chronic cervical catarrh, it is essential to cure the latter (the cause of the erosion) first, and this is a difficult matter. The removal of the hypertrophied endo-cervical glands and mucous membrane by the sharp curette, and cauterization of the base with strong nitric acid or the actual cautery, is usually an indispensable preliminary to a successful treatment of the catarrh. Occasionally I have found it necessary to apply nitric acid, or pure chromic or pyroligneous acid to the erosion, before a change for the better allowed me to return to the milder astringents and iodoform. In every case it is well to notify the patient that the cure is certain, but that she must persevere for several months, at least, or she will not recover.

In a few intractable cases I have found the negative pole of a galvanic battery, applied by means of a round button to the erosion, the positive sponge being placed over the abdomen, to produce a marked tendency to cicatrization.

If all means fail, he would pare the erosion with scissors, and unite the raw surfaces with sutures.

2. Laceration of the cervix, unhealed or temporarily healed. In these cases an examination per speculum will generally reveal the presence of a small patch of hyperplastic papillæ or granulations just within the cervical canal. He snips them away with scissors, and sears their base with strong nitric acid, using astringent after-treatment until the surface is healed. So long as the cervical canal gaps, a return is not impos-

able; a permanent cure is therefore only to be had by restoring the integrity of the cervix by trachelorrhaphy.

3. Chronic subinvolution of the uterus. Here he makes application of Churchill's tincture of iodine to the endometrium twice a week during the inter-menstrual period, taking care to make the application thorough by repeating it at the same sitting until any oozing of blood, which may possibly occur, ceases. The usual hot water injections are taken twice daily. These iodine applications should be continued up to the very inception of the flow. He has seldom failed to keep the hemorrhage within bounds by this treatment, which he has always practised at his office. He also gives a pill of ergot, gr. j.; sulph. iron, gr. ij., and strychnine, gr. $\frac{1}{10}$, three times daily.

If the flow should still be too profuse, he puts the patient to bed, and after four or five days does not hesitate to check it by the iodine application and firm tamponade, repeated daily until effectual. At the same time he gives rectal suppositories of ergot, three to five grains each, three times daily. In a few cases the fluid extract of viscum album, in teaspoonful doses every two or three hours, has kept the flow in bounds.

Patient and physician should remember that usually several months of the above treatment will be required to insure a permanent benefit or a certain cure.

4. Chronic hyperæmia of the uterus. In this condition he found the above described iodine applications invariably effectual.

5. From retention of blood by flexion or pin-hole external os.

The treatment of this case is perfectly simple. Remove the obstacle to the free discharge of the blood, make the whole uterine canal of equal width, and the menstrual blood will escape from the external os as it is poured out into the uterine cavity, and all discharge will cease as soon as no more blood is exuded. This is best done by making a so-called crucial incision of the external os, dividing the mucous membrane covering the cervix to the length of about one-fourth of an inch, and then trimming off each little flap with fine curved scissors, so as to make the external os funnel-shaped. Then, by stretching the uterine canal with divergent dilators, and, if thought advisable, swabbing it with tincture of iodine, this little operation is completed. Dilatation once a week for several weeks, or even several months, is essential to prevent the orifice from contracting again, and the iodine application may be repeated once or twice, if there be a hemorrhagic tendency in the endometrium.

He lays great stress on the necessity of speculum examinations in all cases of non-puerperal hemorrhage, to ascertain the cause, and cites several cases where women have been for years unavailingly treated, when by ascertaining the cause they were at once relieved.

Experimental Investigation of the Action of Chloral, Opium, and Bromide of Potassium.

In an essay on this subject in the *Brit. Med. Jour.*, March 24, 1883, by Dr. Sidney Ringer, Professor of Medicine in University College, London, and Dr. Harrington Sainsbury, the authors

make the following observations on certain well-known drugs, after discussing the physiological effects of the agents mentioned in the title of their paper: "Clinically, the dangers of bromide of potassium and of chloral have been recognized; and thus in our text-books, we find the statements that the presence of grave adynamic symptoms contra-indicate chloral and bromide of potassium. Opium, on the other hand, in such adynamic states, frequently appears to lend actual support. The results of definite experiment we find to accord with the results of clinical experience; and the value of the former lies in that they confirm, and by their definiteness must tend to enforce, the teachings of the latter. The choice of a drug is, however, no simple matter; an advantage here may be outbalanced by a disadvantage there; and practical men may object that they would gladly give opium, but that the disordered stomach, blunted appetite, inactive liver, and torpid intestines, more than outweigh the advantages of opium administration. This clearly is a matter for consideration in the individual case under treatment; and the decision will have to be according as one or other element, asthenia, or derangement of the digestive, etc., powers, is most to be feared. These objections to opium, on the one hand, and chloral and bromide of potassium, on the other hand, raise the question as to whether, in very many cases, a drug, at present rather extensively used, especially in America, viz., bromide of sodium, might not with advantage be substituted in their place. The salts of sodium generally contrast very markedly with those of potassium; for the chlorides, bromides, and iodides of these two metals, the lowest figure would represent the potassium as ten times as active as the sodium. These precise numbers refer to action on the ventricle of the frog's heart (See *Medico-Chirurgical Transactions*, vol. lxx., concerning the action of the salts of potash, soda, and ammonia, on the frog's heart), but on all hands the evidence is forthcoming that, whilst salts of potassium are very poisonous, those of sodium are very slightly so. One of the marked points of contrast between the two sets of salts to be found in respect of inhibition; potassium salts inhibit the frog's ventricle strongly, sodium salts scarcely at all. Here, however, we are considering drugs as to their cardiac effect; and, in respect of this, sodium bromide would rank far ahead of bromide of potassium, chloral, or opium, as to innocuousness. The objections holding for opium would not apply here, for sodium salts are generally very little disturbing to the tissues. With these advantages the general verdict of clinical experience is to the efficacy of bromide of sodium as a hypnotic, and, indeed, as a substitute for bromide of potassium; and should this position but be maintained, it is clear that bromide of sodium will be in very many cases the sedative above all others to be selected."

Idiopathic Erysipelas in an Infant.

Dr. J. J. Johnstone reports the following case in the *British Medical Journal*, March 3, 1883:

On June 7, I attended the wife of a farmer in her first confinement. The labor was very tedious, the lady being thirty-five years of age: and I had

eventually to deliver with the forceps. The child was a male, healthy-looking and well developed, and what slight marks the instruments left on the head had disappeared by the following day. On June 25, I was sent for to see the baby, who was suffering from indigestion and disordered bowels. I prescribed a few gray powders with soda, which relieved him for the time. On July 8, I was again asked to visit the child, as he had become very restless, and cried a great deal, as if in pain. I found some puffiness in the left submaxillary region, with slight redness of the skin. The bowels were rather costive, and the stomach irritable, nutriment being frequently, but not invariably, rejected. He had been fed almost exclusively on the breast, the mother having an abundant supply of milk. By the next day (July 9), the redness had become deeper, and had spread itself over the left cheek, the eyelids becoming gradually swollen so as to close the eye. On the 10th, the whole of the left side of the head and neck had become affected, and the right submaxillary region showed signs of participating in the disease. The redness and oedema spread rapidly over the right side of the face and head, while the disease receded from the left side, so that by the evening of the 12th the right side of the head and neck was completely involved, the left having to a considerable extent regained its normal appearance. The inflammatory blush invaded, but not to any marked degree, the upper part of the chest and arms. On the evening of the 13th, the left side of the face once more became affected, and the little sufferer sank from exhaustion on the 14th. The pupils acted alike throughout the illness, and there was no strabismus. Internal remedies seemed to afford little relief; but the external application of warm lead lotion on lint covered with gutta-percha tissue appeared to give ease. I may mention that the father of the child died six weeks after his son's decease, from tubercular phthisis of nearly four years' duration. The mother, a half-cousin of her husband, belonged to a consumptive family, but seemed to be quite sound herself.

Spina's Attack on Koch.

Dr. E. E. Saltler gives in the *Cinn. Lan. and Clinic* the following summary of an attack recently made on Koch by Dr. Arnold Spina, of Vienna, one of Prof. Stricker's assistants;

First.—Dr. Spina denies the statements of Koch and Ehrlich, that solutions of the aniline dyes must react alkaline in order to stain the so-called bacilli tuberculosis, and also that acids and aqueous solutions of vesusin do not enter the bacilli.

Second.—He denies that bacteria, which stand in no causal relations to tuberculosis, react in a different way with coloring matter from the bacilli found by Koch.

Third.—He denies the statement of Koch that the bacilli of tuberculosis occur constantly in the tuberculous organs of man. He found that this statement was too far-reaching, and in many cases examined he never found any bacilli. As regards the bacilli in sputa, his results agree essentially with those of Koch.

Fourth.—He was never able to find bacilli in the tubercles which stood in no connection with the

open air—the serous membranes of the body. He says, “I have examined about one hundred and fifty mesenteric and omental tubercles, in the most various stages of their development, according to Koch’s and Ehrlich’s method, and found bacilli in not one case.”

Fifth.—He also criticises the insulation experiments made by Koch with purified bacilli, and says that the specific character of tuberculosis has not been proved by them. He calls attention to the history of inoculation experiments; the conflicting results, the negative and positive results of inoculations with tuberculous matter and indifferent substances, and also gives the results he obtained by inoculations with purified bacilli.

Sixth.—He concludes by saying that the bacilli of tuberculosis are the result, not the cause of the disease.

The Disinfection of Tubercle.

The *Lancet*, January 27, 1883, says that M. Vallin has been experimenting on this subject, and has communicated his results to the Académie de Médecine. Fragments of tubercular pulmonary tissue removed from the body of a man who had died of phthisis were well mixed with distilled water, and fifty centigrammes of the filtered liquid were injected into the peritoneal cavity of a guinea-pig. No inflammation was produced, but at the end of a few weeks the animal began to lose flesh, and died at the end of the fourth month. The liver, spleen, and lungs were full of granulations and grey masses, transmissible by inoculation. It was this secondary tubercular substance which supplied the material for the inoculation experiments. With distilled water, an infusion of caseous fragments of the organs was made, and a sheet of filtering paper was saturated with the liquid and then allowed to dry. It was then cut up in strips of the same width, each of which would yield, to a small quantity of water, a similar dose of the virus. Preliminary experiments showed that the inoculation of this produced tubercle with certainty. Some strips of the paper were exposed to the action of various disinfectants. In a chamber, fifty cubic metres in area, strips were exposed to the fumes of sulphur for twenty-four hours. The results showed that it was necessary to burn twenty grammes of sulphur in this chamber, to render the virus innocuous. When the quantity burned was less than twenty grammes, the animals usually died tuberculous. Boiling water was found invariably to secure immunity, and so also did corrosive sublimate in a solution of one per thousand. The conclusion M. Vallin draws from the experiments is, that it would be well every year to purify by sulphurous fumigation all prisons, barracks, hospitals, and schools.

Inversion of the Sexual Sense.

The *Journal of Nervous and Mental Diseases*, January, 1883, says that under this title Charcot and Magnan (*Archives de Neurologie*, November 3, 1882) report six cases of imperative conceptions respecting sexual matters, which they consider allied to the sexual perversion of the Germans. The first case was that of a masturbator, a physician, who

felt drawn to the anal region of females and clothed children for sexual gratification; the naked bodies were repugnant to him. He was disgusted with the idea of pæderasty and sexual intercourse; there was strong heredity in the case. In the second case there was also strong heredity, and the patient felt sexually attracted by the nails of women’s shoes, concerning which he constructed elaborate romances, and masturbated while gloating over these. The third case also had hereditary defect, and felt sexually attracted by white table-cloths, several of which he stole and was punished for so doing. The fourth patient, also a victim of hereditary defect, was unable to copulate with a woman unless her hair was dressed in a certain way, and she had a night-cap on. The other cases were victims of nymphomaniacal impulses. There is, it will be obvious, very little in common between these cases and sexual perversion as described by Gock, Servaes, Krüg, Kraft-Ebing, Ulrichs, and others. Dr. Hammond (“Diseases of the Nervous System”) has described a case where shoes were the attraction, and Van Buren and Keyes (“Venereal Diseases”) a case where a man was impotent except with women dressed in a peculiar style. As might be expected, impulses of this character are very frequent among hebephreniacs.

Ligature of the Bile Duct.

The *Practitioner* March 1883 says that Beloussow has studied this subject under the direction of Cohnheim and Weigert. He experimented upon rabbits, guinea-pigs, and dogs. The longest time that any animal survived was eighteen days. The liver was jaundiced and slightly enlarged. In its substance were seen yellowish gray spots, varying from the size of a pin’s head to a pea. These were most numerous from the first to the sixth day. The microscopic examination showed them to represent a partial necrosis of the liver substance caused by the pressure of the bile. Around these nodules appeared a zone of reactive inflammation, with the formation of young connective tissue in which were newly-formed bile-ducts. This new tissue gradually replaced the necrotic portions entirely. In this way is to be explained the cirrhosis of the liver observed by earlier experimenters (Wickham, Legg, Charcot, Gombault, and others) after the ligature of the ductus choledochus. This occurred in entirely aseptic cases, and was in no way to be connected with any inflammation starting from the point of ligature and following up the course of the bile-ducts. Kelsch (*Rev. de Méd.*, 1881) records two cases where the retention of bile was followed by cirrhosis—one following closure of the duct by cholelithiasis and cancer of the gall-bladder, the other in which a dilation of the bile-ducts was found without any formation of concretions.

Inosuria.

From the *Medical Record*, March 31, 1883, we learn that Dr. Cochoat concludes a thesis on this subject in the *Journal de Médecine de Paris*, January 13, 1883, as follows:

1. Inosite (muscle sugar) is never met with in normal urine.

2. Urine containing inosite may also contain albumen or ordinary glucose. In some cases, however, the glucose disappears entirely, and is replaced for a time by inosite; or vice versa.

3. Thus inosuria is not a separated disease, but is a symptom which may be met with in Bright's disease or diabetes.

4. Whenever we find inosite in the urine, we have to do with diabetes or albuminuria. The patient is exposed to the same dangers, and the effects of injuries are equally grave.

5. Since inosuria may supervene upon glycosuria, it adds another difficulty to the diagnosis of the latter. For inosite does not turn the plane of polarization, neither does it give the characteristic chemical reactions of glucose.

6. Inosuria is to be suspected when the urine, boiled with Fehling's solution, throws down a flocculent precipitate of a greenish color. But certainty is only obtainable by a thorough qualitative analysis.

7. It is of great importance to remember that a patient with inosuria is really the subject of Bright's disease or diabetes, in view of the gravity of operations or of wounds in general in such patients.

The Action of Quinine on the Ear.

Dr. J. Orne Green thus concludes a paper on this subject in the *Boston Med. and Surg Jour.*, March 8th, 1883:

(1) Clinical experience the world over is that quinine occasionally produces serious injury to the ears.

(2) From our present knowledge, both clinical and experimental, we are justified in asserting that the action of quinine upon the ears is to produce congestion of the labyrinth and tympanum, and sometimes distinct inflammation with permanent tissue changes.

(3) That the action of the drug upon the ears should always be considered in prescribing it, and changes in the ears, due to existing or previous inflammation of those organs, constitute a contra-indication to the medicine in large doses or for a long time except under urgent circumstances.

(4) That where large and continuous doses are absolutely necessary an occasional intermission of the administration is desirable, if possible, to diminish the risks to the ears.

Bilharzia Hæmatobia.

The *Lancet*, March 3, 1883, tells us that an interesting contribution to our knowledge of the *Bilharzia hæmatobia*, and its influence on those parts of the human body which it infests, has been recently published by Dr. Zancarol, of Alexandria. As our readers know, the adult worms, which are of separate sexes, inhabit the veins not only of the urinary but also of the digestive tracts. It has been said that the changes so frequently found in the kidneys are the direct result of the presence of the parasite. Dr. Zancarol opposes this view: he points out that the ova and embryos are chiefly confined to the lower quarters of the urinary passages, and believes that the renal alterations are secondary to cystitis. Specimens of kidneys and other parts of the urinary tract

were demonstrated before La Société Médicale des Hôpitaux de Paris, together with microscopical preparations taken from a man who died with the symptoms of uræmia. The right kidney was in a state of marked hydronephrosis. The left kidney showed much fibroid overgrowth in places. The walls of the ureters were notably thickened. The ova of the nematode were detected in but small numbers in the most superficial part of the vesical mucous membrane. A second demonstration was given of the intestines removed from a man who had suffered during life from chronic intestinal ulceration. The surface of the sigmoid flexure was studded with vegetations which, in the fresh state, had the appearance of internal hæmorrhoids. These elevations were found, on microscopical examination, to consist of folds of the mucous membrane, the meshes of the stroma of which were stuffed with the eggs of the parasite. Dr. Zancarol stated that ova from the intestines have a spine which is situated laterally, whilst those from the urinary passages have a terminal one.

Perchloride of Iron in Skin Diseases.

In the *Rev. Clin. di Bologna*, Dr. Carsarini thus sums up his experience:

1. Perchloride of iron is a most efficacious remedy in purpura hæmorrhagica.

2. In the chloro-anæmia accompanying certain skin diseases—as rupia, eczema, impetigo, etc.

3. Its external use is very favorable in scrofulous and syphilitic ulcers.

4. Squamous affections are markedly modified by applications of a liniment of perchloride of iron.

5. It may be used as a lotion, dissolved in two or three parts of water, or as an ointment—one, two, or three grains of perchloride of iron to thirty grains of vaseline [cosmoline] or lard. The author has used it in psoriasis, in the form of a pomade—ten grains of iron, thirty grains of lard or glycerine.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—A well-printed photograph of a microscopic section accompanies the reprint of an article in the *Glasgow Medical Journal*, March, 1883. The article is on the photography of microscopic sections, and is by Dr. James Whitson, who is making a special study of the best photographic methods of reproducing such sections.

—The St. Clair, Michigan, Mineral Spring, sends a pamphlet of 112 pages, describing the sanitary, therapeutic and other advantages to be derived from a visit to that locality. Of course, the pamphlet has been "written up" for an avowed purpose, and hence has no scientific interest. We still need in this country an honest study of our national resources in medicinal waters.

—Dr. Walter A. Taylor, of Atlanta, Ga., has written a pleasant little pamphlet entitled "Sesqui-Centennial Oglethorpe Souvenir."

—The various applications of iodoform in ophthalmic practice is the subject of a valuable paper by Dr. M. Landesberg, of this city, reprinted from the *Centralblatt für praktische Augenheilkunde*.

—The Doctorate address delivered at the recent commencement of the Rush Medical College, Chicago, by Prof. Moses Gunn, is on the general subject of medical ethics, and is well worth reading as a contribution to progressive thought on this vexed subject (pp. 17).

—The thirtieth annual report of the Pennsylvania Training School for Feeble Minded Children, at Media, Pa., contained a number of facts of interest in connection with this excellent institution, and the training of its patients. The Superintendent, Dr. Isaac N. Kerlin, has identified himself with the progress of this branch of medical study in this country, and the establishment under his charge is a model for all of the kind, anywhere.

—Part V. of Dr. Isaac Ott's "Contributions to Physiology," contains a number of curious observations on the poison of the rattlesnake and copperhead, on the action of drugs on plant growth, and on the physiological influence of several therapeutic agents. To be had of the author, Easton, Pa.

—An excellent article, reprinted from the *Glasgow Medical Journal*, and written by Dr. James Whitson, is on some of the advances which have been made in surgery during the last decade. We allow ourselves one extract:

A totally different method of dealing with abscesses is now carried out as compared with the practice of even recent years. Formerly, after incising the cavity and pressing out the contents, the case, with the exception of frequent syringing, was almost entirely left to nature, while recovery in most instances was tedious. At the present time, and with antiseptic precautions, a much more vigorous line of treatment is adopted, and we have no hesitation in removing the pyogenic membrane *en masse*, interference with which older surgeons looked on with disfavor. In order to accomplish this, we make use of Volkmann's spoon, and if the whole of the inflammatory products contained in the cavity are scraped out, two healthy surfaces are left opposed to each other, and which speedily becoming covered with granulations soon coalesce. During the process of healing the less the parts are disturbed the better, and syringing the cavity irritates the tissues composing its walls, and leads to increased discharge—while the progress of cicatrization is interfered with, and as a natural consequence recovery, instead of being accelerated, is considerably retarded.

BOOK NOTICES.

A Manual of Chemical Analysis as Applied to the Examination of Medical Chemicals. Third edition. By Frederick Hoffman, A. M., Ph. D., etc., and Frederick B. Power, Ph. D., etc. Philadelphia: H. C. Lea's Son & Co., 1883. Clo., Svo., pp. 622.

This standard treatise appears in a third edition completely revised, rewritten, in fact, and brought up to the requirements of the latest issues of the United States and German Pharmacopoeias. Its purpose is to furnish an accurate guide for the determination of the identity and quality of drugs and chemicals, and the detection of the impurities and the adulterations to which they are subject, either through accident, ignorance, or fraudulent design. No better guide for this purpose is known to us, and the methods and tests recommended by the authors have been thoroughly examined and repeatedly tried, so that they can be relied upon as the most exact now to be found. The work is somewhat illustrated, and is carefully and neatly printed. It will, no doubt, continue to enjoy the favor with which it has been received already for more than a decade. Certainly the authors have done all in their power to deserve it.

The Physician Himself, and What He Should Add to His Scientific Acquirements. By D. W. Cathell, M. D. Third Edition. Baltimore, 1883. Price, \$1.25.

It gives us pleasure to chronicle the appearance of the third edition of this meritorious work. The author has availed himself of the opportunity to revise it carefully, and has amended a number of points and expanded others. No doubt he will continue to find for it a large and appreciative circle of readers.

The Untoward Effects of Drugs, a Pharmacological and Clinical Manual, by Dr. L. Lewin, Doctor in the University of Berlin. Translated by J. J. Mulheron, M. D. Second Edition, revised and enlarged. Detroit, Michigan: Geo. S. Davis. Price, \$2.

This valuable monograph has very properly reached a second edition at an early period in its history. The subject it treats of is one that few practitioners have not had painful experience in, and is therefore of very general interest. It is needless to say that the author treats it with great skill, and from the results of close study and observation. The present edition has been thoroughly revised, and contains also matter additional to the former one.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

PREGNANCY NEPHRITIS.

A lecture on this interesting subject was delivered by Dr. Reginald Southey, which we find in the *Lancet*, January 13th, 1883.

The disorder assails women, previously healthy, in sequence to their becoming pregnant; begins insidiously, without fever or pain, and proceeds to some grave symptom—rapid general dropsy, sudden convulsion, uræmia or cerebral disturbance—before the patient is aware that anything serious is the matter with her. Mere albumen in the urine of a pregnant woman does not necessarily signify pregnancy nephritis. Abeille* found albumen in one out of every ten pregnant women. Dr. Roberts, consolidating the statistics of several observers, infers the liability of pregnant women with albuminous urine to eclampsia to be about one in four. The nearer to its natural term the pregnancy is conducted, the more likely, in these albuminous cases, is eclampsia to supervene. The subjects of pregnancy nephritis who are prematurely confined most probably escape the eclamptic complication. There are valuable figures collected by Von Wiegner, who tabulated 455 cases showing that the convulsions preceded the commencement of labor in 109 instances, attended the act of parturition in 236, and followed its completion in 110. He describes a typical case, in which, besides general anasarca and dropsy, the countenance was dusky, lips livid, mental condition apathetic and drowsy. Pulse, 72; respiration, 28; temperature, 98.40, tongue furred and bluish; appetite bad; bowels open; solid action; urine scanty, sp. gr. 1028, high colored and containing one quarter its volume of albumen. The sight was bad. The fifth day after admission she gave birth to a dead fœtus; the after-birth came away naturally, and she lost very little blood. The general œdema rapidly subsided; her appetite improved, and for about a week, she passed daily large quantities of urine, some days as high as 132 ounces, while the sp. gr. fell, and the albumen diminished rapidly. All albumen had disappeared within a week after delivery. She took a steel mixture during convalescence and was

*Traité des Maladies albumineuses. Paris, 1863.

discharged, quite well, and with no complaint about her sight, one month after delivery. There are several forms of pregnancy nephritis.

1. There is eclampsia parturientium, a series of epileptic convulsions concurring with the act of parturition, and coinciding with highly albuminous scanty urine, or with anuria (total defect of urine), preceded by no well-defined or usually noticed symptoms of renal disease, for neither slight nor severe anasarca of the legs attending the later months of pregnancy can be accepted as incriminating evidence of prior or primary renal disease. 2. There is chronic Bright's disease, chronic insidious parenchymatous diffuse nephritis, complicated by pregnancy, quickened and rendered more imminently dangerous by uræmic symptoms, or local inflammatory complications, *pari passu* with each week of advancing pregnancy. 3. There is pregnancy nephritis proper, a cortical glandular nephritis, an acute change in the nutrition of the renal epithelium, which commences sometimes as early as the third month of pregnancy, but more often in the sixth, and is attended by diminished urination, albuminuria, anasarca of face and limbs, retinal symptoms, uræmic symptoms, vomiting, neuralgia, lung œdema, asthma, mental perturbation phenomena, convulsions, and sometimes death; but is usually suddenly terminated by premature delivery and subsequent profuse diuresis, and complete recovery.

The case described belonged to the last class. In favor of mere mechanical pressure as its cause are the established statistical facts: (1) That this nephritis happens mainly, if not only, in the latter months of pregnancy; (2) that it affects primiparæ principally; (3) that it complicates twin rather than single pregnancy; and (4) that the anasarca and albuminuria subside rapidly after parturition.

Still there are so many conflicting views held by high authorities, concerning its causation, that we must consider the matter *sub judice*.

The prognosis in the latter class is good, unless they become pregnant again, when the same nephritis is apt to repeat itself. Further experience

teaches us that while with each succeeding pregnancy, dropsy, albuminaria, and uræmic complications recur, the woman becomes more tolerant of her fœtus, the nephritis is continued for a longer time, and the damage to the kidney is more extensive and more apt to pass on to chronic nephritis when delivery is over. He records one case in a relative of his own, who suffered pregnancy nephritis with three successive pregnancies. The first fœtus was born somewhere short of the sixth month, but had been dead six weeks at least; the second was born in the seventh month, dead; the last was carried to term, born alive, and is now alive. Between the first two pregnancies all albumen disappeared from her urine; after her last pregnancy and delivery, albumen remained persistent until her death by uræmia.

Advice upon treatment.—Distinguish between the three varieties of pregnancy nephritis already noticed. Eclampsia parturientium with albuminous urine, but without notable dropsy, is relieved by chloroform, chloral, amyl nitrite, nitro-glycerine, blood-letting, warm baths, by all those things which relieve spasm, by completed delivery. Chronic Bright's disease, complicated by pregnancy, is best treated upon the ordinary plan for Bright's disease, and its several accidents, by hot baths, warmth, careful dietary, gentle purgation. True pregnancy nephritis demands the induction of premature labor, the earlier the better, and requires that the medical man should plainly inform his patient of the risks to life entailed by any future pregnancy. The dropsy may also require relief by draining with fine canulas, to avoid the risks of laceration of the genitalia and invitation of septicæmia.

A TERRIBLE EPIDEMIC OF INTERMITTENT FEVER AND ITS CAUSE.

Dr. Bennett, a deputy sanitary commissioner, has just filed his report of an epidemic of intermittent fever occurring in the city of Amritsar, in the province of the Punjab, in the autumn of 1881. The total deaths were 6,859, of which 3,531 occurred in children under twelve years of age. As many as 10,000 cases were under treat-

ment in one day. From the *British Medical Journal*, March 24, 1883, we note that Dr. Bennett unhesitatingly attributes the outbreak to an excessive rainfall, obstructed drainage, and water-logging of the soil. During the months of July and August, a fall of thirty-eight inches was registered, being twenty-four inches above the average of the previous ten years; while that for September was under the usual average. In consequence of this excessive downpour, a large portion of the ground about the city was covered with water, and that in the city wells rose to about six feet from the surface. Indeed, in one portion, where both the drainage and outfall are extremely defective, the water in several of the wells actually rose to a level with the ground. After this inordinate rainfall, the atmosphere was heavy and moist to an unusual degree; while, from the damp soil, drying up under the influence of a hot sun—the ground-water at the same time beginning to subside—organic emanations from the decomposing animal and vegetable matter contained in it, must have been given off in great abundance. Many intelligent natives blamed the well-water as being one of the main causes of the outbreak. Analysis showed that the well-water must have been polluted with organic impurities; a fact, however, for the proof of which chemistry was hardly needed to any one acquainted with the character and surroundings of Indian compounds. No doubt, one of the chief causes influencing the mortality was the injurious effects of great alternations of temperature. In October, especially during the latter part of the month, cold dewy nights were superadded, when bronchitis, pneumonia, diarrhoea, and dysentery became frequent concomitants of the sequelæ, and not unfrequently proved fatal. Another cause which materially tended to swell the death-rate was unsuitable and deficient clothing; an evil much aggravated by the custom prevalent amongst the populace of sleeping on the ground with, as a rule, only a thin cotton sheet pulled over them, or a mat intervening between their bodies and the cold, damp floor.

A WORD ON THE TREATMENT OF SYPHILIS.

We are gradually growing to look with less and less dread and caution upon the *disastrous* effects of mercury when syphilis does *not* exist, and as we do so, we are less afraid to employ it.

It would seem, therefore, that whenever a patient comes under observation who confesses to having had, or where there exists any reasons to suspect that he or she may have had syphilis at some period more or less remote, we are justified in giving specific treatment.

We have seen an eight-ounce mixture, containing $\frac{1}{8}$ grain of the biniodide of mercury and 80 grains of iodide of potassium taken by a patient in whom there was only the *slightest* possible suspicion of a remote infection, without any result, *good or bad*, being manifest.

While we do not recommend the *indiscriminate* use of mercury and potassium, yet we hold that the ramifications of syphilis are so numerous and so intricate, that in many obscure and obstinate cases of departure from health, where we can *carefully* watch their effects, they will often prove useful where all other means fail.

These words are suggested by a case recently reported by Dr. R. B. Davy in the *Cinn. Lan. and Clin.*, March 31, 1883.

The patient was a highly respectable gentleman, aged 70, who had an ugly and intractable ulcer on his leg, which resisted all treatment until he was given iodide of potassium and bichloride of mercury, when it kindly and rapidly healed.

He then admitted having had a chancre fifty years before, followed by constitutional symptoms, and that every ten years since he had return of the manifestations, which always yielded readily to specific treatment.

By bearing in mind the great prevalence of the syphilitic poison, its liability to recur, the profound influence it exerts on diseased conditions, and the comparative innocence of *carefully* watched specific treatment, we will frequently be enabled to secure good results where hitherto we have failed.

IT SERVED THEM RIGHT.

The value of intelligent sanitary legislation and the penalties of its neglect are every now and then made painfully apparent to all.

The latest instance comes from North Carolina, and we note the following from the *North Carolina Medical Journal*, for March, 1883:

"In our remarks on the defeat of public health legislation, (February) we hinted at the shocking violation of decency and sanitary rules, constantly practiced in the Capitol. Since then we get news of some of the practical results of these abuses in the serious illness of two clerks employed at the Capitol. Their disease is typhoid fever, and there is at present no doubt that the cause of the disease is directly due to the unhealthful conditions of the atmosphere in which they worked.

It is shameful, that of the number of representative assembled at Raleigh during this winter, that not a man raised his voice in condemnation of the filthy practices there enacted.

If ever a State needed the sanitary advice of a board of health, and a one-man power to execute unflinchingly this advice, that State is North Carolina.

The victims of the pestilence-breeding air have our earnest sympathy, and we only wish that it could have fallen to the lot of members of the Legislature, instead of the innocent; then, perhaps, we would have had a sanitary reform inaugurated in the future."

While we sympathize with any sick person, yet we repeat, "it served them right"; for they helped to put in power these very men, who so shamefully neglect the most important duty they owe their fellow-men.

MORE ABOUT THE ELECTRIC LIGHT IN SURGERY.

From the *Brit. Med. Jour.*, January 27, 1883, we learn that the incandescent electric light has been lately adopted by a few surgeons for operations about the mouth, and that dentists are likely to find it exceedingly useful. The globe containing the incandescent material is enclosed in another globe, and mounted on a handle of suitable form; after its introduction into the mouth, the circuit can be closed, and the light immediately obtained. The light is extremely pure and clear, and all shadows are cast down and away from the operator. It is calculated to be exceedingly useful for operations for cleft palate. The amount of electricity required to be stored is not great, as the light is only maintained for the time that the operator actually requires; and Faure's accumu-

lators, which are already a commercial product, are well adapted for the purpose.

NOTES AND COMMENTS.**Small and Frequent Doses.**

M. W. Vaudenburg, M. D., writes a letter to the *N. Y. Med. Jour.*, March 10th, 1883, which contains some pertinent points, principally gleaned from a lecture by Prof. A. A. Smith, in the same journal for February 10th:

"Urticaria is often caused by the administration of *full doses* of balsam of copaiba. * * * * A single drop of the same drug given every half hour will sometimes control urticaria."

As is well known, arsenic in large doses produces vomiting; half a drop of Fowler's solution, every half hour, will relieve vomiting following a debauch, also the vomiting of drunkards. Such is the case with ipecacuanha. Minute doses of calomel are efficacious in infantile diarrhoea.

A single drop tinct. nux vom. every ten minutes relieves sick headache not of neurotic origin. In larger doses the stomach is disturbed.

Large doses of cantharides will cause inflammation of the urinary tract; a drop of the tincture every hour will not infrequently relieve vesical catarrh.

We all know how pleasantly castor oil acts in diarrhoeas of children, the dose however must be small. The letter concludes thus:

"Copaiba produces and cures urticaria; arsenic causes and cures vomiting from more or less acute gastritis; atropia causes and cures a false croup; ipeca causes and cures vomiting from great nausea; it also causes and cures a certain kind of diarrhoea, and to this may be added that the diarrhoea is most frequently accompanied by nausea; calomel causes and cures night headaches; it also causes and cures vomiting, also diarrhoea; corrosive sublimate causes and cures diarrhoea, marked by tokens of acute inflammation; tartar emetic causes and cures a discharge from the bronchi; cantharides causes and cures acute cystitis; castor oil causes and cures diarrhoea with jelly-like passages. In every candid mind the question cannot help arising, are these twelve drugs, so widely different in their nature and physiological effects, acting as they do on so many different parts of the organism, the only ones subject to these generalizations?

"Clinically demonstrated facts are in order. What is the breadth of these generalizations?"

Cysto-Abdominalorrhaphy.

Surgeons do not agree as to the best method of dealing with supra-pubic incision of the bladder. A safe operation, as set forth by Alex. W. Stein, M. D., (*Medical Record*, March 17, 1883,) is to bring the bladder wound in apposition and in union with the abdominal wound. As this procedure has been carried out but once in the human subject, Dr. Stein experimented eight times upon dogs, and when we reflect that the bladder in dogs is covered on all sides by peritoneum, it will be seen that the operation in these cases was intra-peritoneal.

In three cases union by first intention was not obtained, but adhesions prevented the escape of urine into the peritoneal cavity; in one experiment, two-thirds of the incision healed by first intention; the three other experiments of healing by first intention was secured throughout; in one case a fistulous tract remained.

In all cases the autopsy revealed firm adhesions between bladder and anterior abdominal wall. Some hypertrophy of the bladder wall was also noticed, caused, possibly, by the abnormal attachments of the viscus.

It may be said that the eight experiments were successful. In man, perfect quiet, the recumbent position, constant drainage of bladder by catheter, Listerism, etc., are available factors which will contribute vastly to a speedy recovery of a cysto-abdominalorrhaphy.

Galvanic Treatment of Locomotor Ataxia.

There are many authorities who believe that the starting-point of posterior sclerosis had to be searched for in the brain, and not in the spinal cord. Dr. W. B. Neftel is one of these, and if we are to judge from the result of his electrical treatment based upon this opinion, the latter will have to be considered the correct one. N. reported some years ago cases treated after his method (Cbl., 1882, p. 536), and recently he has published again a series of cases, in whom he galvanized the brain for several months in succession (Cbl., 1882, p. 864). The ascending constant current is applied to the spine first stabile then labile. The earliest stages should, according to N., be treated for months. N. made the new observation, which is the main cause that we mention his method here, that contrary to the normal condition, viz., the excitability of sensory fibres is by the kathode more intense than by the anode. The opposite takes place frequently in persons suffering from tabes dorsalis. In the course of treatment, together with diminution of pains

and of the ataxia, the normal reaction may return. Should this observation of N. be confirmed, the peculiar electrical reaction mentioned may become an important point in differential diagnosis in doubtful cases, and especially in such of recent origin.

The Salicylates and Hemorrhages in Enteric Fever.

In our issue of March 31, we made reference to this subject. In answer to the statements therein made, Dr. Henry Tomkins thus writes to the *British Medical Journal*:

In the *Journal* for February 17, appears a communication from Dr. Fergusson, of Perth, suggesting that the use of the salicylates in enteric fever is attended with increased liability to intestinal hemorrhages, and asking that other observers should record their experience on this point. Having used this agent for the reduction of the temperature in typhoid fever very extensively during the past four years, I am in a position to state, from my own observations, that such is not the case here. I am constantly in the habit of prescribing ten to twenty grains every two hours whenever the temperature remains continuously at 103° or thereabouts, and have for some time been struck with the fact that the intestinal irritation, as shown by diarrhoea, is actually lessened. This point is alluded to in a paper on the subject, published by me in 1881, where a detailed account of the results obtained in forty-six cases of a severe character will be found. Since that time, I have treated a much larger number in the same manner, which I hope shortly to publish as a continuation of the former series.

Indian Treatment of Syphilis.

We can often learn many valuable therapeutic points from "old women," why can we not do likewise from those, who possessing no regular physicians, must cure their ills by the teachings of unaided experience? In the *British Medical Journal*, March 10, 1883, Dr. J. Marion Sims thus relates the preparation of a decoction that has been used with great success in the treatment of syphilis among the Creek Indians:

"Fluid extract of *smilax sarsaparilla*, fluid extract of *stillingia sylvatica* (queen's delight), fluid extract of *lappa minor* (burdock), fluid extract of *phytolacca decandra* (poke root), āā ȝ ij.; tincture of *xanthoxylum carolinianum* (prickly ash), ȝ j. Take a teaspoonful in water three times a day before meals, and gradually increase to tablespoonful doses.

"In making the fluid extracts, there is some

risk of getting a remedy less efficient than the original Indian decoction, because the manufacturer may use roots that have been kept too long, and lost some of their active principles, while the decoction used on the plantations was always made of fresh roots just gathered from the woods. In making the fluid extracts, we should therefore be careful to have them made from roots recently gathered."

Illustrations of Rare Skin Diseases.

At a recent meeting of the Academy of Medicine in Ireland (*Dublin Jour. Med. Sci.*, January 1883), Dr. A. W. Fort presented the following:

(1) Photographs of pachydermatocele (von Mott), taken from a woman, married, aged thirty, never out of Ireland. The disease had existed nine years; origin attributed to a severe wetting, followed by irritation of the inguinal glands; nates and genital organs unaffected. Died four days after the removal of the large mass springing from the posterior femoral region.

(2) Drawing of ichthyosis vera, from a peasant boy, aged eleven, affected from early life, but not born so. Discharged from hospital free from scab, scale, or roughness after five weeks' treatment, consisting of warm baths, cod-liver oil internally, inunction of a compound of isinglass and glycerine.

(3) Drawing of diffuse melanomata from a washerwoman aged fifty-seven, whose right eye was excised for melanosis. Five years afterwards she was studded all over with melanotic tumors of various sizes.

Pregnancy with Occluded Vagina.

The *Med. Times and Gaz.*, January 27, 1883, says that Dr. Hyernaux, Surgeon of the Brussels Maternity, communicated to the Belgian Royal Academy of Medicine (*Presse Médicale Belge.*, 1882, No. 45), a remarkable case of a woman aged twenty, who was brought to the Maternity with what seemed commencing pains of labor. On examination an imperforate hymen was found to exist, through which no aperture could for a long time be detected, until at last the rounded extremity of a very fine probe passed into an extremely minute one. The hymen was incised, and found to be five millimetres in thickness. The finger was then introduced into the vagina, which was quite free, and the presentation of the foetal head with a thin os uteri detected. Labor did not come on until a week later, when it terminated naturally in a few hours with a girl weighing 2800 grammes. It seems the young woman

had, when she was seventeen years of age, undergone a puncture of the hymen for the discharge of menstrual fluid, and since that time she had, until the period of conception, a slight monthly discharge.

Cæsarian Operation.

Dr. G. Leopold performed recently the Cæsarian operation on a woman æt. 29 (*Arch. f. Gyn.* xix. p. 400). Cause: generally narrowed rachitic pelvis to a high degree, the form of the pelvis being that of a blunted card-heart. The operation which was made according to the modified procedure of Sänger (compare *Arch. f. Gyn.* xix. H. 2.) was successful for both mother and child. L. dissected off after removal of child and placenta the serosa of the uterus on each side of the longitudinal cut to a distance of one ctm., and then resected from the cut a triangular piece of the muscularis uteri, similarly as it is now usually made in the amputatio supra vaginalis uteri fi bromatosi. The suture was performed in such a manner, that the silver wire penetrated deeply through the serosa up to the decidua and the dissected pieces of the serosa were laid between the margins of the wound. Besides there were made many superficial silk sutures uniting the serosa. L. is of the opinion that the modified procedure of Sänger will limit more and more the operation of Porro, which will find application in only a few well-selected cases.

Resection of the Stomach.

This operation cannot be classed among the successes of surgery. In a summary of the cases in the *Lancet*, March 24, 1883, we note the following points: Pylorotomy or partial gastrectomy has been performed twenty-nine times, once in 1879, once in 1880, fourteen times in 1881, and thirteen times in 1882. Twenty-three succumbed shortly after the operation, none living more than eight days. In one case of so-called cure, a recurrence of disease (cancer) occurred at the end of four months; in another the patient was in good health two months after the operation, but no further information is forthcoming of the remainder.

Edema Uvulæ Threatening Life.

Dr. Charles H. Carter, of Chicago, reports in the *Medical News*, March 31, 1883, the case of a boy aged 19, who was apparently suffering with a simple pharyngitis, for which a seidlitz powder and a chlorate of potash gargle were ordered. In

a few hours he was summoned in great haste, to find the patient choking and gasping for breath. An examination revealed the uvula so swollen that it completely filled the whole inter-tonsillar space, and pressed hard upon the dorsum of the tongue, and as he could not breathe through his nose, the uvula and palate evidently closed that passage also. The uvula was so distended as to be almost transparent. The swelling was freely punctured with a bistoury, with immediate relief. Tannic acid was added to the gargle. A bilateral suppurative tonsillitis followed, which ran a typical course and ended in recovery in two weeks.

Probable Tubal Pregnancy.

To the Obstetrical Society of New York (*New York Med. Jour.*, January 28, 1883) Dr. Hanks said that he had been called in consultation by Dr. Bradsdew to see a multipara who should have menstruated on the 16th of October, and who very soon after felt pain in the region of the left ovary. When he saw her, which was about the 1st of November, she was losing considerable blood. He ordered ergot and opium, and directed the vagina to be tamponed. Afterward, on removing the tampon, a very small ovum, with the membranes, was discovered in the blood which had been discharged. The depth of the uterus in the direction of the right ovary was about three inches, while in the direction of the left ovary the depth was four and a half inches, which would seem to indicate tubal pregnancy on the left side.

Cardiac Aspiration.

Of all bold surgery, the boldest seems to be the absolute invasion of the sacred walls of the heart with sharp steel; yet such is done. In the *Med. Record*, March 10th, 1883, Dr. F. M. Corwin describes a case of chronic nephritis and cardiac hypertrophy, where because hydropericardium was suspected, a hypodermic syringe was plunged into the right ventricle and an ounce of dark venous blood drawn up into the syringe. There were no bad results, and when the patient died, two days later, an ecchymosis was found at the seat of puncture. Dr. C. says he has frequently performed cardiac aspiration, but never saw any benefit. Let us utter a word of caution, lest we have some suits for manslaughter among our ranks.

External Hemorrhoids.

According to the *Drug Cir.*, Dr. Blascho, of Berlin recommends compresses soaked in a one per

cent. solution of ergotin to be applied hourly. D. Pasqua, of Florence, gives the following ointment as infallible: Extract of Belladonna, gr. v., iodoform, acetate of lead, aa gr. j: petroleum jelly, $\frac{1}{3}$ j. Make into an ointment, to be applied three or four times a day.

Signs of Convalescence in Typhoid and Scarlet Fever.

La France Médicale says that, according to a communication received from Dr. Chauffard, the occurrence of multiple superficial abscesses and that of polyuria are two signs of convalescence in typhoid fever. The *Lyon Médical* states that M. Manjot, in giving a description of an epidemic of scarlet fever at Belley, said the defervescence was always marked by an extraordinary slowness of the pulse. This slowness could not be attributed to a nervous or cardiac lesion, nor to the treatment or any toxic influence. It appeared on the fifth or sixth day, when the eruption began to fade, and continued during the desquamative stage until convalescence. The pulse fell to 44 and 46 for eight or ten days, and then slowly rose to 60. The slowing was a sign of near recovery.

An Alterative Tonic.

The following is said to be Dr. Goodell's favorite mixture:

R	Hydrarg. bichlor.,	gr. j-ij.
	Liq. arsen. chlor.,	$\frac{1}{3}$ j.
	Acidi. hydrochlor. dil.	
	Tr. ferri, chlor., aa	$\frac{1}{2}$ ij.
	Syr. zingib.,	$\frac{1}{2}$ ij.
	Aque ad.	$\frac{1}{2}$ vj.—M.

Sig.—Two teaspoonfuls three times daily in water, after meals.

The Yellow Fever Plague Fly.

Before the Norfolk (Va.) Med. Society Dr. Tunstall spoke of the yellow fever plague fly, declaring that in 1855 the fly appeared there about the time that the fever did, reached its greatest number during the worst of the epidemic, and gradually disappeared with it.

Paralysis from Injections of Ether.

In the *Rev. de Therap.*, March 15th, 1883, Dr. Arnozan relates four cases from which he concludes: 1. That injection of ether into the muscles causes paralysis. 2. These paralyzes are analogous to peripheric paralysis. They cause suppression or diminution of faradic excitability. 3. They pass away spontaneously, but very slowly.

CORRESPONDENCE.

Iodoform in Diphtheria.

EDS. MED. AND SURG. REPORTER:—

In a late number of the REPORTER I noticed "Iodoform Treatment in Diphtheria." A few days after had an extremely bad case and tried it. The result proves that "iodoform" dusted on the membrane once or twice daily is a wonderful curative agent. The fetor is completely obliterated, and the disease very much abbreviated. The inventor of the treatment should be considered a public benefactor.

JAMES BATES, M. D.

Paris, Ohio.

Salicylate of Soda in Granular Conjunctivitis.

EDS. MED. AND SURG. REPORTER:—

I have accidentally discovered that a solution of salicylate of soda when applied with a soft camel's-hair brush to the everted lid in cases of granular conjunctivitis, after a saturated solution of sulphate of copper has been used, will almost instantly relieve the pain and irritation caused by the solution of copper, thus securing its good effect, without the accompanying evils of that valuable remedy. The discovery was made in this wise: I have a son, a youth of eighteen, who for several years has been very much troubled with granular conjunctivitis. I have had him under the care of some of the best oculists in the West without receiving any permanent benefit. About the first of January a most violent exacerbation came on which threatened to destroy his eyes; the cornea of both eyes became thickened and opaque—in fact he was almost blind. I started with him for Cincinnati for the purpose of having him treated by specialists in diseases of the eye, but the great flood came on, the trains were stopped, and I was compelled to return home with him. With many misgivings, I began to treat his case myself. I had previously used Pagenstaken's ointment of the yellow oxide of mercury, with not very satisfactory results. I now concluded to try the saturated solution of the sulphate of copper; this was very painful, though I washed it off thoroughly after each application; then, in order to relieve the excessive pain, I made a mucilage of quince seed which I would brush over the lids before turning them down. This afforded some relief, and I could see that the eyes slowly improved, but in time the mucilage became mouldy and became itself irritating. In order to preserve the mucilage from mould, I added about 6 or 8 or 10 grains of salicylate of soda to each ounce of the quince mucilage. On making the next application to his eyes, to the surprise and delight of both of us, the pain was almost instantly relieved and his eyes begun to improve much more rapidly, until now, a little over five weeks from the beginning of this plan, his eyes are almost well. I have also found that the mucilage may be dispensed with, as the salicylate of soda with pure water acts more promptly and equally well. I believe that the salicylate of soda not only relieves the pain, but has a good effect in curing the granulation. It is better to make it fresh occasionally. This discovery will be a great boon to those suffering with trachoma,

and you are at liberty to publish it if you think fit. I would suggest also from its promptness in relieving pain in this instance that it might give equally prompt relief in burns.

Respectfully yours,

E. T. SPOTTSWOOD, M. D.

Perryville, Ind.

The Topical Effects of Kerosene.

EDS. MED. AND SURG. REPORTER:—

Observing in some of the late numbers of your valuable journal some discussion as to the topical effects of kerosene, or coal oil, I thought that perhaps a bit of my experience with it might not be unprofitable.

During the winter of 1880-81, I had a patient, a little girl, aged about eight years, sick with typhoid fever, complicated with pneumonia and incipient morbus coxarius. The pain in the hip and thigh, and in fact the whole leg, was most excruciating, and the little patient was a terrible sufferer from it. While this condition was present, one of those women who think they know more than the doctor, came in one day, and suggested to the parents the application of coal oil to the limb.

The matter was referred to me, and I stated that I had no special objection to its use, and gave my consent, supposing of course that it would be merely rubbed on as a liniment. Instead of this, however, the woman saturated flannel cloths, and swathed the limb and hip with them, and covered these with other layers of cloth. The result was, that at my next visit, upon removing the cloths, the entire epidermis came off with them, leaving the entire limb, the back part of the hip, and the lower part of the back, devoid of this natural and useful covering.

You may well believe that I had hard work to save the little patient, with this addition to the already almost hopeless condition, but by dint of careful management and faithful nursing she recovered.

I learned by this that in applying coal oil not to confine it closely if I did not want it to blister.

B. C. BELLAMY, M. D.

Livermore, California.

NEWS AND MISCELLANY.

American Laryngological Association.

The fifth annual convention of this Association will be held in the hall of the Academy of Medicine, No. 12 West Thirty-first street, New York city, commencing Monday, May 21, 1883, at 10 a. m., and continuing during the two following days.

An Overdose of Chloral.

Lady Catherine Petre, widow of the late Hon. Arthur Petre, and the youngest daughter of the late Earl of Wicklow, was found dead in bed on December 21. By her bedside was a bottle containing chloral. She had been in the habit of taking chloral as a sleeping draught, and the medical opinion was that death resulted from an overdose taken inadvertently.

Wisconsin's Insane.

The Governor of Wisconsin, in his annual message, January 11th, calls attention to the necessity of caring for the insane in properly equipped State hospitals, and strenuously advises against the employment of jails and almshouses as asylums.

Sanitary Exhibition in Berlin.

New buildings have been constructed in lieu of those burned last spring, and the postponed sanitary exhibition will be held in Berlin, under the auspices of the Emperor, Empress, and Crown Prince, commencing May 1st.

State Board of Health for Kansas.

A bill to create a State Board of Health for Kansas has been introduced in the House, and referred to a special committee, composed exclusively of physicians. A favorable report is expected soon. There are strong hopes for its passage at an early day.

Juvenile Tobacco Statistics.

The head master of the Latin School at Boston, Mass., states that tobacco is used by half the boys in the upper classes in his establishment; while the Principal of Harvard Grammar School, in Charlestown, avers that out of 300 boys, about 40 per cent. use tobacco habitually.

Prize for the Solution of the Question as to the Prevention of Pollution of Rivers.

The king of Saxony offers a prize of a silver "jardinière," with nine hundred marks, to be awarded by the German Fishery Commission for the best essay on "The Pollution of Water-courses and its Prevention, with special reference to the Maintenance of the Life and Health of Fish."

Essays are to be sent to Dr. P. Boerner, 8 Burggrafen Strasse, Berlin, W., before December 31st, 1884, from whom further information may be obtained.

West Virginia State Medical Society.

The Medical Society of the State of West Virginia will hold its sixteenth annual session in the court house at Grafton, commencing at 2 o'clock p. m., Wednesday, May 16th, 1883.

The last meeting was the largest the society has ever held, and a greater number of medical papers were read than in any previous year. It is confidently expected that this increased interest will be productive of even better results at the coming meeting.

All who contemplate presenting papers are requested to send title at their earliest convenience to S. L. Jepson, M. D., Secretary, No. 81 Sweet street, Wheeling, W. Va.

American Medical Association.

The thirty-fourth annual session will be held in Cleveland, Ohio, on Tuesday, Wednesday, Thursday, and Friday, June 5th, 6th, 7th, 8th, 1883, commencing on Tuesday, at 11 a. m.

Secretaries of medical societies are earnestly requested to forward, at once, lists of their delegates.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those

who have forfeited their membership, the Secretaries are, by special resolution, requested to send to him annually a corrected list of the membership of their respective societies.

W. M. B. ATKINSON, M. D.,
Permanent Secretary,
1400 Pine street, Philadelphia.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, January 1st, to March 31st, 1883.

Bailhache, P. H., Surgeon. Detailed as member of Board, for the examination of the officers of the Revenue Marine Service, March 27, 1883.

Murray, R. D., Surgeon. To proceed to Vicksburg, Miss., as inspector, March 24, 1883.

Purciance, George, Surgeon. To proceed to Cleveland, Ohio, to investigate management of hospital, January 22, 1883.

Granted leave of absence for seven days, February 8, 1883.

Austin, H. W., Surgeon. To proceed to Gallipolis, Ohio, as inspector, January 9, 1883.

Fisher, J. C., Passed Assistant Surgeon. Detailed as member of Board for the examination of officers of the Revenue Marine Service, March 27, 1883.

Carter, H. R., Passed Assistant Surgeon. To proceed to New Orleans, La., for temporary duty. Thence to San Francisco, Cal., for duty, February 7, 1883.

Porter, F. D., Passed Assistant Surgeon. Granted leave of absence for thirty days, February 10, 1883.

Guiterah, John, Assistant Surgeon. Granted leave of absence for thirty days, January 19, 1883.

Wheeler, W. A., Assistant Surgeon. To proceed to Chicago, Ill., for duty, January 27, 1883.

Armstrong, S. T., Assistant Surgeon. To proceed to Key West, Fla., for temporary duty, February 1, 1883.

Bennett, P. H., Assistant Surgeon. To proceed to Charleston, S. C., for temporary duty, February 19, 1883.

Resignation.

Porter, F. D., Passed Assistant Surgeon. Resignation accepted to take effect March 31, 1883, February 10, 1883.

Commencement of the University of Pennsylvania.

The annual commencement of the Medical and Dental Departments of the University of Pennsylvania was held in the Academy of Music on Friday, April 13. The exercises commenced with prayer by Bishop Stevens.

The degree of Doctor of Medicine was conferred upon ninety-nine graduates, while there were thirty-four graduates in Dentistry.

Prizes were then awarded as follows:

Dr. Spencer Morris prize of \$100—George R. West, of Rome, Ga., for "Marked proficiency in differential diagnosis and hygiene."

Dr. J. William White prize, copy of *Agnew's Surgery*—Dr. Radcliffe Cheston, of Maryland, for "Proficiency in bandages and operating."

Morbid Anatomy prize—Dr. Edward Martin, of Philadelphia.

Dr. John B. Deaver (Demonstrator of Anatomy) prize for the best anatomical preparation—Dr.

William H. Mercur, of Towanda, Pa., and Dr. Edward Randall, Jr., of Galveston, Texas, with honorable mention of Dr. J. B. Hamilton, of Washington, Pa.

Dr. John B. Deaver Anomaly prize—Dr. William H. Krecker, of Philadelphia, for the "Greatest number of anomalies collected in the dissecting-room," with honorable mention of Dr. George R. West, of Rome, Ga.

The Honorary Degree of LL. D. was conferred upon George L. Harrison "in recognition of his philanthropic services, his eminence as an authority on sociological questions, and his scholarly attainments."

The valedictory was delivered by Prof. R. A. F. Penrose.

Medical Society of the State of Pennsylvania.

The Thirty-fourth Annual Meeting will be held in Norristown, on Wednesday, Thursday, and Friday, May 9, 10, and 11, 1883, commencing on Wednesday, May 9, at 9 a. m.

Amendment to be acted on.

By Dr. C. K. Mills:

That Rule IX. of the Rules of Order be amended so as to allow a suspension of the rules by a two-thirds vote of the members present.

Appointments for 1883.

To prepare address in Surgery, Dr. Alex. Craig, Columbia.

To prepare address in Obstetrics, Dr. G. O. Moody, Titusville.

To prepare address in Hygiene, Dr. Henry Leffmann, Philadelphia.

To prepare address in Mental Disorders, Dr. John Curwen, Warren.

To prepare address in Medicine, Dr. James Tyson, Philadelphia.

On Codifying Lunacy Laws, Dr. B. Lee, Philadelphia, Chairman.

Secretaries of County Medical Societies are earnestly requested to forward *at once* complete lists of their *Officers and Members*, giving the *post-office address of each*.

Every *delegate*, before admission, shall produce a certificate of delegation, signed by the President or Secretary of his County Society.

Every *permanent member (not a delegate)*, before admission, shall produce a certificate of good standing in his County Society.—(*Extract from Constitution.*)

WM. B. ATKINSON, M. D.,
Permanent Secretary.

1400 Pine St., Philadelphia.

Railroads.—The Penna. R. R. and its branches, and the Phila. and Reading R. R. and its branches, will issue excursion tickets at the rate of two cents a mile. All who desire to avail themselves of this should notify the Permanent Secretary, stating the number of excursion orders required, and the railroad over which the party must travel to the place of meeting.

—It is proposed in Paris that a medical service be formed for the purpose of ascertaining what chronic or constitutional diseases affect the teeth, eyes, or ears of the pupils in the public schools, and of devising suitable remedies for the ailments.

Personals.

—Prof. von Arlt has been decorated with the star of a Commander of the Order of Francis-Joseph.

—Prof. Maas has been appointed Professor of Surgery in Würzburg, in the place vacated by the resignation of Prof. Bergmann.

—Subscriptions are being made in Paris to erect a statue to Pinel. The sum of five thousand dollars has already been raised.

—Dr. R. S. Huidekoper has been elected Professor of Veterinary Anatomy and Pathology in the proposed Veterinary Department of the University of Pennsylvania.

—The widow of Pirogoff has given the University of Moscow 12,000 roubles, the interest of which is to be applied to the endowment of two lectureships in the name of Pirogoff.

—Prof. Charcot, of Paris, has been elected an honorary member of the Royal Irish Academy for his important researches in pathological anatomy and physiology, especially of the nervous system.

—Prof. Neumann, the successor to the chair of the late Professor von Sigmund, in the University of Vienna, on February 8, delivered an eloquent eulogy of his predecessor, in which he claimed for him the honor of first having instituted a systematic clinic of his specialty.

—Sir Erasmus Wilson, although now in his seventy-fourth year, is not yet past work, his present studies being Egyptological. He is the President of the Biblical Archaeological Society, and Treasurer of the Society for the Exploration of the Buried Cities of Egypt. He is also one of the Court of Assistants and late Master of the Carriers' Company.

Items.

—A school for the systematic training of nurses has been started in Cincinnati, under the presidency of Dr. Geo. B. Orr.

—The Iowa College of Physicians and Surgeons held its commencement March 6, and granted diplomas to three graduates.

—M. Ch. Labourin claims to have detected in man a direct communication, other than the capillaries, between the vena cava inferior and the portal vein.

—The Medical College of Hamburg has issued a protest against the too frequent use, without medical advice, among the laity of chlorate of potash.

—The Legislature of Indiana recently defeated the Bowers bill to regulate the practice of medicine in that State by a vote of (in the House) 46 to 41.

—The manufacture of drugs and chemicals in the United States involves a capital of \$28,598,458. Products to the value of twenty-eight millions are annually made.

—In 1879 the number of lunatic asylums in Spain was 26, with a population of 3,790, which gives a ratio of one to 2,250 of the whole population. About eight per cent. are discharged cured every year.

THE AZORES AS A HEALTH RESORT.

BY DR. J. M. JUNKIN,
Of Philadelphia.

These islands, belonging to Portugal, are located in the Atlantic Ocean, within latitude 37° to 40° , and longitude west from Greenwich 25° to 31° , about as far north as Philadelphia and Baltimore, and yet the climate, for the whole year, is very much the same as we have in Philadelphia in the month of May.

Take the weather we have in May; both for cool and warm, wet and dry, it will just about give the average for the year in the Azorean islands.

There never is any frost, and though quite hot in July and August, it does not reach the extremes it does here, but is more continuous.

To avoid the discomforts of the hottest weather, many of those who are able to do so have summer residences up on the sides of the mountains; the facilities offered by the numerous volcanic elevations giving abundant opportunity for this luxury.

These islands, nine in number, are Flores, Corvo, Fayal, Pico, St. Jorge, Gracioca, Terceira, San Miguel, Santa Maria. The soil is rich, and by careful cultivation may be made to produce from two to four crops a year, or even more of the quick-growing crops. They are all of the same volcanic formation; some of them are thrown to higher elevations than others; this makes more difference than at first thought one would suppose; for on account of high winds and the clouds hanging on the higher ground, there is no cultivation much above 1,000 feet from the sea level.

This is the case, especially, with Fayal and Pico, where scarcely half of the actual surface is under cultivation.

The people say that "each island is different in climate from the others in some respects." I think this will account for it.

The remains of the old feudal system still exist, though it is nearly worn out; but the land, especially on San Miguel, is held by a comparatively few proprietors. The evil effects of this are evident in the poverty of a large portion of the people; many of them, even old men and women, go entirely bare-footed, and are thinly clothed; they must be rather uncomfortable in the cooler days of the winter months, for sometimes the thermometer gets as low as 50° .

There is comparatively little sickness on any of the islands—very rarely any regular fevers, or epidemics of any kind, prevail.

The streets of the larger cities are remarkably clean, and are lighted by kerosene lamps; and they have a well organized police force. I never saw the streets of any city as clean as those of Horta.

The air is quite moist, though not at all disagreeably so, and is very balmy. This makes it peculiarly desirable for cases where there is a tendency to dryness of the mucous surfaces of the air passages. In some forms of asthma it acts like a charm, and the disease is entirely checked as long as the person remains. I don't know that old, confirmed cases could be entirely cured, except by a permanent residence; but I have no doubt that a residence of even a few months would effect wonders in more recent cases.

There are few places in the world where more

benefit could be received in that very distressing disease, commonly called, but very improperly, "hay fever"—for it is not a fever, and is not caused by hay.

The air has also a peculiar effect on the skin, removing harshness and rendering it soft and smooth. Nor does it produce that relaxing effect on the physical strength, causing repugnance to exertion, which tropical climates do.

At the city of Horta there are no springs within reach, so water is supplied only by wells and cisterns. The latter are all private. There are many public wells on the streets, all very neatly fitted up, with smooth-cut stone curbs. There are no pumps or other means provided for raising the water; every one has to bring his own bucket and rope. The water is mostly good, but some of the wells are brackish. In all the other cities, and often by the roadsides, the water is supplied by clay pipes from springs. It is very clear and pure, being almost distilled water, from the clouds resting so much on the hills. There are many fountains along the streets, and at every place there are two openings, and a large cut-stone trough to catch the waste water. I understood that the two openings were to prevent contentions in case two persons reached the fountain at the same time.

At the three large cities—Horta on Fayal, Angra on Terceira, and Ponta Delgada on San Miguel—there are educated physicians; as also at the Furnas, of which I shall say more farther on.

The roads.—The Portuguese Government has shown a most liberal spirit in providing roads. I think I can say, without the fear of contradiction, that there are no better in the world, if as good. I did not think that roads could be made as smooth as I found those on these islands. Many of them, especially on the island of San Miguel, are literally as smooth as a floor. It is a luxury to ride on them, and there is no toll charged on any of them. Carriages can be had at moderate prices, and they are quite comfortable; drawn by mules; there are very few horses on the islands.

The most interesting and important object of all, especially as a health resort, is the valley of the Furnas. This beautiful valley is the bottom of a vast crater, from two to three miles wide and four or five long, about 1,000 feet deep, entirely surrounded by the crater walls, except a narrow rent out to the sea on the south side, through which the water escapes from the various springs. It contains a thriving village, a number of handsome gardens, and a good deal of cultivated

ground, with a beautiful lake nearly a mile wide and two miles long. There is a large hotel and a number of private houses, where visitors can be accommodated.

At the eastern end of the lake, there is a single boiling spring; but it has no arrangements for bathing. The bathing springs are more than two miles to the eastward of this, near the border of the valley. A ridge sloping down to quite a narrow, rounded end, divides the boiling spring from the others.

On the south side of this, extending for half a mile or more, are numerous springs, some quite hot, but not boiling; others of all temperatures to quite cold. These do not contain sulphur, but are all pleasantly chalybeate, and all highly charged with carbonic acid gas. I saw it bubbling up everywhere. The amount of gas discharged, both at these and at the boiling spring, is enormous; and if it were not for the rent through the wall of the crater, by which it escapes to the sea, it would make this a valley of death—no living thing could go into it and remain alive.

On the other side of this ridge are the boiling springs. There are three large openings, where the water is thrown up with great violence, with immense quantities of carbonic acid gas. The large columns of steam arising from these are one of the first objects that attract the eye on descending into the valley.

There are a great many smaller openings where boiling water escapes, and numerous fissures where jets of steam are constantly emitted, so that persons have to be very careful where they step, lest they get their feet scalded. At one large opening there is constantly being thrown up a bluish mud, which is largely alumina, but must contain sulphur and other matters mixed with it.

It is thrown up with great violence and a horrid noise. The people call it the mouth of hell, and it is not inaptly named. Most of the mud falls back, only small quantities being scattered out on the rocks by the force of the escaping steam and carbonic acid. It is scraped up and used by the people as an external application in skin diseases. I had no opportunity of ascertaining whether it is of any real benefit. Judging from the fact that there are plenty of finger-marks where it is collected, and no mark of any instrument, there is some superstition about the collecting it; and no wonder, for the whole thing presents a diabolical sensation to one looking at it.

There are a number of small bath-houses near

these springs, and more are building; some of these are private. The water is strongly sulphur.

All the boiling springs are contained in a space of not more than forty yards in diameter, and not twenty yards from where the boiling water flows out there is a clear cold spring, with no sulphur in it, but decidedly iron, and so highly saturated with carbonic acid that it is a delightful drink; I never tasted so agreeable a tonic. That one spring would be a fortune to any one, if he had it in this country. The Portuguese Government has shown a very liberal spirit here, as well as in making roads. There are two roads, each twenty-eight miles long, from Ponta Delgada, and they are the *best of the best*. But this is not all.

In the first place, they have not allowed this wonderful laboratory of nature to be taken possession of by private parties and made a speculation of, as is done in our country with everything of the spring kind, hot or cold, as well as other great objects, such as the Mammoth Cave, etc.

In the second place, in providing, at great expense, baths free for all. There are several old small public bath-houses, with only a few rooms altogether; they have large stone tubs, made of the black lava-rock. Since the value of the springs has become known, the number of visitors has increased, so that larger accommodations were needed; and the government has, at great expense, put up an almost perfect bath-house. There is nothing in our country, public or private, to equal it.

The building is large, two stories high. The lower story is fitted up with neat, comfortable bath-rooms, with cut stone floors and marble tubs brought from Lisbon—each one cut from a single block and finely finished—with mat before each tub to stand on, seats and clothes-racks, etc., and each tub has three stop-cocks, for hot sulphur, and warm iron, and cold water. All free; any one can go and take whatever kind of a bath they please, there being no charge—the bathers furnishing their own towels, and, if they choose, giving a small coin to the person who keeps things in order.

To bring the boiling water to the new bath-house, a tunnel has been cut through the ridge to the boiling springs, and pipes are laid through this to the bath-house, which is on the other side.

The upper story is fitted up with a number of rooms for hospital purposes, and an office for a resident physician, who is sent out from Portugal during the summer months. I believe he is to remain permanently when all the arrangements are completed. The building was not entirely

finished when I was there. I am sorry I cannot give an analysis of these waters. There is considerable difference in the different springs, and they must be very beneficial in a variety of diseases.

Many persons from the different islands visit these springs, as well as from Portugal and other parts of Europe; and as their value becomes better known, and the facilities for getting there are improved, the number will increase. The demand will create the supply in both directions.

Attractions.—Many are the objects of interest to attract visitors to these islands beside the delicious climate and the springs. The scenery is exceedingly fine, and being entirely volcanic, is very different in many respects from ordinary scenery. The islands are formed by one or more high volcanic elevations, with vast numbers of smaller ones, varying from fifty to thousands of feet in height. I could count from our hotel window at Horta from fifty to sixty on the western end of Pico alone.

The grandest of the scenery is on the islands of Fayal and Pico. Immediately across from Horta, six miles distant, the beautifully-shaped cone of Pico, "the peak" commences, extending 7613 feet above the level of the sea—nearly a mile and a half up into the air. It is seen from all parts of Fayal, and its great height makes it a conspicuous object a long distance at sea; it has even been proposed as a point from which to start as the meridian of longitude. Visitors ascend to the top in the summer months. Snow generally covers the top in January, and ice often remains on it until June. It has no crater, being nearly level on top, with a small depression in the centre, and a small sharp cone, about three hundred feet high, rises on one side of this.

Nine miles back from Horta, near the centre of the island of Fayal, is the "Calderia." The whole island is one volcano, with the immense crater, the rim of which is 3400 feet above the sea, nearly round, two miles across the top, and about 1700 feet deep. It is very difficult to comprehend these large measurements, and it is only by comparing them with familiar heights and distances, that we can form any conception of the vastness of this huge cauldron.

The view from the rim is grand beyond description, and well repays any one for the fatigue and difficulty of the ascent.

The rides and drives on Fayal, but more especially on San Miguel, are exceedingly enjoyable; the smooth roads and beautiful views, the fertile hills and valleys, and the delicious climate with

its never-ending verdure, make this a luxury which few, if any other parts of the world can equal. For miles wherever you go, the fence-walls are covered with ferns and vines and parasitic plants, with flowers in great variety lining the roadside.

The gardens are the great attraction, nothing has been neglected to bring these gardens to almost perfection. The rich soil, and semi-tropical climate, combine to give a rare luxuriance to vegetable life.

The gardens of Bagatella and Freedonia, belonging to the estate of the U. S. Consul at Horta, are revelations of beauty; one can stroll for hours beneath the shade of almost every variety of trees, brought both from tropical and other climates. Palms in great profusion, orange and lemon, camelias and fuchsias grown to trees, covered with magnificent flowers—roses of every kind, the richest and rarest that our earth produces, and other flowers and plants innumerable.

Prince among the trees is the Norfolk Island Pine (though it is really a spruce). In one of these gardens is the first one ever grown north of the equator. Truly it is a magnificent tree, with its branches covering a circle of about forty or fifty feet on the ground, and towering a perfect cone over one hundred feet in the air, with its heavy, rich, deep green foliage.

The gardens at Ponta Delgada are admitted by all to excel those at Horta. It is said they are not equaled in the world, and well it may be so; for the genial soil and climate seems to suit trees, plants, and flowers, whether from temperate or tropical regions. No expense has been spared by the wealthy land-holders. They have searched the world over for everything, tree, shrub, or flower, that would add beauty to their gardens. To attempt to name the different varieties would be to give a botanical catalogue.

In many respects the garden of Senhor Antonio Borgio excels all the others. It is not large, but is filled with the most exquisite surprises, with its countless varieties of grand trees, and myriads of the more delicate ferns, vines, and flowers, arranged in lake, glen, dell, and grotto. Words would fail to give any correct idea of it. One must see it for himself to form a conception of its beauty. With all its fruits and flowers, it comes nearer to what is generally understood by the word Paradise than probably anything else the world now contains.

Accommodations for visitors—At Horta there are two good hotels where the English language is spoken. Connected with one of these is a very

large garden, surrounded by high walls, its broad avenues lined with trees, under which are rustic seats, large orange groves and banana walks, the smaller fruits in abundance, such as guavas, nespas, etc. • Flowers here too, in their profuse and luxuriant growth, exhale their delicious perfume, and the little olive canaries make the air vocal with song. This is a cheery spot, and a most desirable one for invalids, as they can be entirely secluded amidst all these delights.

At Ponta Delgada there is one very pleasant, homelike hotel, delightfully situated, on high ground overlooking the sea. There are several others which are regular Portuguese.

In all these, the accommodations are very good; The beds not very soft, but clean and nice, and the table equal to any of our city hotels, where two to three dollars a day is charged. The fixed price in all these hotels, is one dollar (or 12,000 reas) a day. Comfortable accommodations may be had in private families at lower rates for a continued stay.

There are a few English-speaking families in all three of the largest cities, which make a pleasant society. Persons not speaking Portuguese can get along with but little difficulty, as there are many who are able to speak English.

The means for getting there.—The question may be asked, How is any one to get to the Azores? I feel that this article would not be completed unless it afforded an answer to this question.

There is no communication by steam except by way of England and France, and then by taking a Brazilian steamer to San Miguel, or by going overland to Lisbon and taking the small mail steamer, which makes the round trip, to all the islands, twice every month.

There are two lines of sailing vessels, one from Boston, the other from New Bedford, Mass. O. L. Bartlett, 115 State street, Boston, would gladly afford all needed information about these lines. I speak from experience when I say that the barque "Sarah," of their line, is a staunch vessel; she is a fine sea-boat, and carries herself splendidly in rough or smooth seas. She is commanded by a gentleman—Captain Hale—hearty and generous, a thorough seaman, ever watchful for the safety of his vessel, and the comfort and pleasure of his passengers.

The run is made in from sixteen to twenty-five days to Fayal. Of course, depending on the wind and weather, precision cannot be attained as on a steamer; but as for passing the time, a sailing vessel is more pleasant and comfortable than a steamer, excepting there is not as much space;

and there are far more disasters of steamers than of sailers, in proportion to the numbers of each. So no one need be deterred from going on a sailing vessel from fear of disaster, and the length of the voyage may be desirable.

The trip is a comparatively cheap one, and can be made inside of three months, giving two weeks at Horta and two at Ponta Delgada, and a day or two at Flores and Terceira.

Should a family wish to keep house, comfortable houses can be had for moderate rent. Marketing is very cheap compared with our prices, and servants' wages are not over one-fourth of what they are here.

A NEW UNIVERSAL BATTERY.

BY CARL SEILER, M. D.,
Of Philadelphia.

The application of electricity in medicine is becoming more generally recognized as a curative agent in the treatment of disease, and as an aid in surgery, and it is therefore necessary to pay some attention to the source of the agent, viz. the battery, and make it as convenient and efficient as possible; and particularly is this necessary when electricity is to be used in surgery, for every surgeon who has used the batteries in the market, has been annoyed by their inefficiency at the moment when wanted for an operation. This defect lies chiefly in the complicated mechanism and the smallness of the cups containing the acid in the portable galvano-cautery batteries, which makes it difficult to keep every connection in working order, and in the bulkiness of the stationary batteries. There is, however, another very serious defect in these batteries when operations in the cavities of the nose or throat are to be performed with the galvano-cautery knife, which consists in the fact that the heat cannot be augmented or diminished during the operation without the aid of an assistant, and without interrupting the current; for the plates are entirely immersed in the exciting fluid, and the current can only be increased or decreased by increasing or decreasing the number of plates in the circuit.

Recognizing the great value of galvano-cautery in minor surgery, and noticing their defects, I endeavored to construct an apparatus which would be under perfect control of the operator, would be simple and easily taken care of, and at the same time would always be ready without any preparation, such as filling the cups with acid, washing the plates, etc. Such a battery, roughly made by myself, but giving entire satisfaction under

the most trying circumstances, I exhibited several months ago at a meeting of the Philadelphia County Medical Society, a short description of which was published in the *Philadelphia Med. Times*. My aim was, however, to obtain an office battery which would combine within itself the different forms of apparatus giving the different kinds of electricity, viz. the galvano-cautery, the galvano-faradic and the galvanic currents, and thus making it of universal usefulness.

My friend, Mr. Otto Flemming, of this city, the well-known manufacturer of medical batteries and apparatus, to whom I showed my working model, altered and perfected its details, and finally produced a battery which leaves nothing to be desired for universal usefulness as an office battery, as will be gleaned from the cut and the following description:

Two systems of ten zinc and carbon plates each are suspended from two hard rubber platforms, Fig. 1, *f* and *f'* placed side by side in the top of the box. A brass spring is connected to each plate by a screw passing through the platform, and presses against a cylindrical commutator, by turning which the plates can be connected for quantity, i. e., all carbons and all zincs connected together, each lead to a binding post, *d*, *e*, *e'* and *d'*; the carbons of the first system being connected with the zincs of the second system by the strips of brass connecting the binding posts *e* and *e'*; or for intensity, i. e., zincs and carbons being connected with each other alternately. Alongside of the platform *f* is another one, upon which are mounted the binding posts *c* and *c'*, which are connected by flexible cords carrying pins with the plates of the system in such a manner that the cord from the post *c'* leads to the spring marked O, the pin being inserted in a hole drilled into the head of the screw connecting the spring with the plate below the platform. The other post *c* carries a double cord, the pins of which may be inserted into any of the screw-heads of the systems of plates, and thus any number of pairs from one to twenty may be brought into action without interrupting the current. The posts *b* and *b'* serve to connect the cords leading to the electrodes. Upon the same platform are also mounted a polarity-changer and a two-point switch for interrupting the current if it is desirable; these appliances being used where an intensity of current is made use of. At the end of the box a galvano-faradic apparatus is inserted, which may be removed and used separately, and away from the battery, a description of which is not necessary, as it is so well known.

In the lower portion of the box are two movable platforms, which may be raised or lowered by a treadle, to which they are connected by cords running over rollers. Upon these platforms are placed two hard rubber cups six inches square by eight inches deep; and in these the exciting liquid, a mixture of bichromate of potash, sulphuric acid, and water, is contained. These cups being immediately beneath the system of plates, suspended from the platforms, when raised by the treadle, cause the plates to be immersed in the fluid, and thus a current is established which

cups of the same size, partitioned off into ten compartments each, are substituted for the open cups, so that when the cups are raised, one carbon and one zinc plate fit into each compartment. This substitution of one kind of cup for the other is readily effected, since the back as well as the front of the box opens, and the cups can be easily removed or inserted into their position on the movable platform. Below the faradic apparatus are drawers for containing the instruments, connecting cords, etc. The size of the box containing the whole apparatus is 28 inches long by

FIG. 1.

varies in strength according to the amount of surface of plates exposed to the action of the acid. A ratchet hook at the bottom of the box, by engaging in the bar of the treadle, will keep the cups at any desired height, so that the foot may be taken off; and by disconnecting the cords of either one or the other of the movable platforms, either one or the other of the cups alone may be raised when only a comparatively weak current is desired. When the plates are connected for intensity, and the galvanic current is to be used.

12 inches wide and 16 inches high, and is therefore not too large to be easily moved.

Mr. Flemming has constructed several sizes of these batteries, such as a battery of one cell, for galvano-cautery only (Fig. 2), one of two cells, etc., all based upon the same principle.

From this description it will be seen that the apparatus has a very wide range of usefulness, and can be applied to any purpose for which electricity in medicine is used. Its great advantage as a galvano-cautery battery over other batteries

of this kind consists in the facts that the operator can regulate the heat of his platinum loop to a nicety by the pressure of his foot, and is, therefore, independent of an assistant, a very important point when small operations in the nose or throat, or about the genital organs, are to be per-

FIG. 2.

formed. Further, that as soon as he lifts off his foot the liquid leaves the plates, and no further action on them can take place, thus saving the zincs as well as the strength of the fluid; the quantity of the fluid being very large, the products of the chemical action of the acid upon the zinc fall to the bottom, and thus the upper portion of the fluid remains fresh for a very long time, so that the fluid need not be renewed more than once in two or three months, according, of course, to the number of times the plates have been immersed. The simplicity of the connections, and the fact that they are placed above the platforms, out of the reach of the fumes of the acid, renders them but little liable to get out of order, and thus the battery is always ready when wanted. But this battery may also be used for other than medical purposes; and when connected for intensity with the partitioned cups, I have used it to work an electric motor for operations with the dental drill and burr, and have obtained an admirable illumination for laryngoscopic and other purposes from incandescent lamps or a small ark light.

THE small-pox epidemic in South Africa appears to have almost subsided.

HOSPITAL REPORTS.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Cirrhosis.

The examination of the first patient by one of the medical students brought out the following facts. He was admitted to the hospital August 7, 1881. Name, J. M.; age, 44; born in Ireland; occupation, a copying or writing clerk; married. His father died of old age—at the age of seventy-eight. His mother died suddenly of heart disease. A sister died of consumption at the age of eighteen. A brother died of small-pox when a child. There are two still living and in good health. He has had no venereal or malarial disease. When ten years old, he had small-pox. He was a steady drinker for twelve years, but did not get drunk. After that he drank to excess until a year and a half ago, and since then he has been abstemious. He enjoyed good health until May, 1880, when he began to lose his appetite, and to have indigestion, and nausea, and other gastro-intestinal troubles, until they became so bad that he came to the hospital for treatment on May 20, 1880. He was then found to have nausea, vomiting, diarrhœa, swelling of the feet and legs, and a mitral systolic bruit, with hypertrophy of the left ventricle. He had a protrusion of the gut through the anus, due to hemorrhoids, and sometimes there was blood in the passages. On the right wrist was observed a spot of subcutaneous hemorrhage. On June 28, 1880, he was discharged from the hospital. Twelve weeks ago he was troubled with pain and swelling in the ankles and knees. So he again came to the hospital, and was relieved by medicine. Since then, he has suffered from flatulence, and eructations of wind from the stomach, and dropsy in the abdomen. His urine is diminished in quantity, and is growing steadily less. It contains twenty per cent. of albumen, and some hyaline and other casts, and it has an ammoniacal odor. He has been treated with digitalis and acetate of potash, and has been cupped and poulticed over the kidneys, but with little good effect. He still has protrusion of the gut, and piles, and blood passages. There has been general œdema, involving the face at times. For ten or twelve days he had a profuse diarrhœa, with nausea and vomiting. On August 13, at four o'clock in the afternoon, he had a chill followed by pain, and then loss of power in the right arm and leg, and especially in the great toe, and his pupils were found contracted, but equally so. He has been aspirated six times, and large quantities of fluid were drawn off. Since the last tapping he has had no appetite, and has suffered from dyspnœa.

Inspection.—The abdomen is immensely swollen, and the superficial veins very prominent. The thorax is flat, and symmetrical on both sides. The face is flushed, and the arterioles and capillaries are prominent upon the cheeks and nose, but there is no œdema at present. The conjunctivæ have a slightly bluish tinge. On the legs are numerous macules of some size, and one or two scars. Visable carotid pulsation.

Palpation.—Fluctuation in the abdomen is very distinct. The apex beat is half an inch below and one inch outside of the normal position.

Percussion.—There is tympanitic percussion on the top of the abdomen, but at about six inches either side of the umbilicus flatness begins, showing that the abdomen is nearly filled with fluid. The patient lies on his back. The size of the spleen cannot be made out because it is covered by the fluid, but its upper border is in about the normal position. The liver is somewhat contracted in size and is lifted up slightly by the fluid. The pulmonary resonance is normal.

Auscultation.—A valvular murmur is heard with the first sound of the heart, and is most distinct at the second intercostal space on the left of the sternum, but is not heard at the apex. It appears to be an aortic obstructive murmur. The respiratory murmur is about normal over the whole of the chest, so there is no pulmonary œdema.

Gentlemen, you have here a very full history. But I now want to call your attention first to his previous illness, for which he came to this hospital a year ago last summer. You remember that he suffered then mainly from gastro-intestinal symptoms, and he comes back now, still complaining of the same. I wish to fix your attention on these symptoms, so that you may see how this malady has insidiously but steadily increased for years. The gastro-intestinal catarrh is the initial symptom in a long line of symptomatology. Stop a moment and ask yourself what was the cause of this catarrh. It was hyperemia of the mucous membrane lining the intestines, and this congestion was due to obstruction in the portal circulation, which in this case was caused by the chronic atrophy of a cirrhosis of the liver. This disease progresses slowly but surely, and the first prominent symptoms are those for which this man came in here a year ago. And now he comes back again with an abdominal dropsy. As this portal difficulty advances, it finally manifests itself by causing effusions of serum from the serous coats of the intestines, and thus originates the ascites, which is the form of dropsy peculiar to chronic atrophy of the liver. In addition to his dropsy, this patient has had albuminuria. This is not a necessary, but it is a frequent complication. For the disease may extend to any other parenchymatous organs, and so we may get a cirrhotic kidney, with all its symptoms. But this is not all. For here we have an hypertrophied left ventricle and a valvular murmur in the heart. The sequence of the complications here, is from the liver to kidney and then to the cardiac lesions, and not from the heart to the hepatic and renal affections, as might at first be supposed. Jaundice is not a necessary symptom in cirrhosis of the liver. But the complexion is rather striking in this disease, from the absence of discoloration of the skin. The prominence of the minute red vessels on the cheeks, seen here, is quite characteristic. You observed that the superficial veins over the abdomen were enlarged. The mechanism of this is, that since the portal veins are obstructed the circulation is carried on chiefly through the superior epigastric and internal mammary vessels, which are hence engorged and made prominent. This is always a symptom of

portal obstruction, and the most frequent cause is cirrhosis. On feeling of the radial arteries here, we find the coats thickened and hardened, and there is more tension to the pulse than is natural. The artery feels like a whip-cord, and rolls under the finger. So we conclude that the coats of the arteries are diseased also, and hence that the cirrhotic disease is generalized and involves both the parenchymatous organs and the coats of the blood-vessels, in this man's case.

Since this patient came in here, the treatment has been mainly palliative. His dropsy has been relieved by tapping as often as was necessary. This has been done six times, and about 260 ounces of fluid were removed at each aspiration. This operation gives great relief, and is perfectly safe to resort to, and it is the only means of giving the patient speedy comfort. When the abdomen becomes filled with fluid, the viscera are forced up against the diaphragm, and aspiration sometimes becomes necessary in order to avoid death from apnoea. The only precaution to be observed, is not to take all the fluid away at the first tapping. For when the great distension of the abdomen has kept up a continued pressure on the blood-vessels for a long time, it is sometimes dangerous to remove all of this pressure suddenly, for the distended vessels do not contract promptly, and so are not quite filled with blood, and syncope which may be fatal is the result. So much care is not necessary in subsequent tapings. It is best to perform the operation with the patient in the recumbent position. It is remarkable how quickly the dropsy will recur. This man was tapped last Tuesday, and now the abdomen is full again.

I have tapped one patient twenty-two times, within a period of six or eight months. The other methods sometimes employed for getting rid of the dropsy, such as diaphoretics, diuretics, and cathartics, are slow and uncertain, and often inefficient. This man has been taking digitalis as a diuretic, and this is a happy selection in his case, for it also acts as a heart stimulant. But there are other points in the treatment to be considered. This man has been suffering more or less from gastro-intestinal symptoms, and especially from wind in the belly. It is a very unpleasant condition to have the abdomen distended by gas and fluid, at the same time. This is one of the consequences of the catarrhal state of the mucous lining, and it may be relieved by washing away the mucous exudation which impedes digestion, and so sets up fermentation and dyspepsia. The best means for accomplishing this is to administer saline cathartics every day or two. And this is being done with this man. More can be done for the dyspepsia by giving the mineral acids, and especially by using care in the selection of foods. The dietetics of sick people are very much neglected, and are left altogether too much to the judgment of the family or the nurse. Our knowledge on this point is very largely empirical, but we know enough of the causes of weak digestion in sick people to enable us to make a selection of a rational diet. As much stress should be placed on the feeding of the sick, as on the administration of medicines. Such a patient as this man must be fed with the greatest care. He should never be allowed to take any of

the fermented preparations of alcohol, such as beer and wine. They are absolute poisons to a man in this condition. Sweetened foods of any kinds should be avoided, as they add much to the gastric distress. They are seldom tolerated in fevers or other sickness. But nurses and friends give these sweets too much, thinking that they will be agreeable to the patient. The proper diet should be simple and consist mostly of animal food, such as milk, meat, and broths, and very little starchy food. If stimulants should be needed, pure diluted alcohol should be administered, but this should be given only rarely. This condition has been brought about by the use of alcohol, and it is not going to be cured by a dog of the same hair. It may only be given at times to stimulate digestion and to cheer him up. But it can do no permanent good.

MEDICAL SOCIETIES.

KENTUCKY STATE MEDICAL SOCIETY.

THURSDAY AFTERNOON.

(Continued from page 432.)

Dr. Thos. F. Rumbold, of St. Louis, by invitation, read a paper on the Treatment of Chronic Nasal Pharyngeal Catarrh. Dr. Rumbold holds that chronic inflammation of the nasal is not like the inflammations of mucous membranes in other situations; therefore he holds that the general practitioner of medicine, while he may understand the usual effects of applications of medicines in situations in general, is not capable of treating inflammations seated here, unless acquainted with the action of drugs in this particular situation. The cause—at least one of the most prolific of causes—of inflammations here is cold, oft repeated and neglected. He speaks of the modification which age exerts upon the process as seated here. Children and young persons show little inconvenience from exposure to a draft of air, while aged persons suffer quickly and severely. Men die from excesses; women from exposure. In order to treat naso-pharyngeal catarrh successfully, attention to these two points of lowered vitality in the two sexes must ever be borne in mind. Particular attention must be paid to the manner in which females are clad, and if this be not under the control of him who undertakes to treat such diseases, his reputation is likely to suffer in proportion to the failure of his treatment. In the means of applications of remedies to the disease, he objects strongly to the douche. It can do no good, because it fails to make the application at the seat of the disease. It may be productive of harm because it is unscientific. Dr. Rumbold objects to the application of water either hot or cold, and maintains it is harmful because it is absorbed by the mucous membrane, and produces a greater state of congestion in it than existed before the application was made. Three essential qualities should be possessed by all applications made to the nasal mucous membrane. First, they should cause no pain; second, they should cleanse the surface; third, they should be capable of transformation into such a form as to

permit their application to every portion. All applications before being made should be brought to the bodily temperature, then they should be applied in the form of spray. Vaseline he recognizes as the best application with which he is acquainted. Two others exhibited and occasionally used were carbolic acid and eucalyptol. This paper was courteously received, but not discussed.

Dr. W. O. Roberts, of Louisville, reported several cases of head injuries in which operative procedures had been rendered necessary. The first was that of a man who had suffered a depressed fracture of the left antero-temporal region. On the eleventh day after the injury he was seized with violent pain in this region. Four days later he had a distinct chill, and soon after it was discovered that he had lost the power of speech, and was paralyzed on the left side. A diagnosis of intra-cranial abscess below the external wound was made, and trephining advised. The operation was done, but the result was nil, no pus nor blood escaping. The next day the patient died comatose. Post mortem examination revealed an abscess situated on the posterior surface of the cerebrum.

The next case was that of a fireman knocked from the cab of an engine. He fell through a trestle work to the ground below. When found, he was insensible, with a gash along the left cheek and a cut on the left antero-temporal region. A sharp-pointed rock near him was noticed to be covered with blood and hair, on which he had evidently struck. He was roused to consciousness, and walked the length of twenty-five cars, when he was put on the train and brought to Jeffersonville, Ind., several miles from the scene of the accident. He walked three squares from the depot to his home. On the second day convulsions supervened, and he soon began to lose the power of speech. By the seventh day it had failed entirely. Late in the evening of the next day I saw him, when it was decided to enlarge the original wound and expose the depressed fragment if possible. This was done; the fragment was discovered and lifted out with a grooved director. Dark grumous blood to the amount of half an ounce escaped. The patient recovered, and was present at the meeting for exhibition.

Another case of a boy 6 or 8 years of age was seen four days after his admission into St. Mary's Hospital. The wound occupied the centre of the left frontal bone. Several days elapsed from the date of the injury to the ushering in of unpleasant symptoms. The depressed fragment was then elevated, though the trephine had to be used in order to get the elevator under it. Pus immediately began to flow. Later a hernia of the brain occurred, followed shortly by dissolution.

Two other cases in which the result of trephining was successful were reported, but your reporter failed to get them.

Dr. D. W. Yandell exhibited the skull of a woman who was operated upon by Dr. Gross in 1854. In 1867 she began to have epileptic convulsions, which continued to occur until her death, in 1872.

Over the opening made by the trephine in this skull, a fibrous membrane of considerable strength had grown. Just inside an excrescence

the size of a pea was formed. From the irritation caused by this, it is supposed the epileptic manifestations arose.

Another case of which he spoke was that of a man shot during the war in the frontal region, and who, apparently fully recovered, was seized with epileptiform convulsions in 1867. Dr. John O'Reilly, since deceased, operated upon him, removing quite a small portion of bone. He made a good recovery, and is alive to this day.

A youth kicked by a horse near the centre of the frontal bone had a comminuted fracture slightly depressed, but recovery took place without interference. In about two years he began to have epileptiform convulsions, and his temper underwent a change. I operated upon him; his epilepsy disappeared, his viciousness passed away, and he is now a useful citizen.

Dr. McCormack, of Bowling Green, said: "A case was brought to my office a little more than a year ago to be examined in order that I might testify as to his sanity. He was twenty-three years of age. Six years before, he was struck on the head with a sharp-pointed hammer, at which time he fell unconscious, and remained so for some time, but gradually recovered without any symptoms of trouble. He married at nineteen. He continued, to all appearances, well until about six months before he came to see me, when he began to complain of great pain in the region of the former wound. He underwent some degree of emaciation. There was distinct depression at this point, though the excessive tenderness there prevented entirely satisfactory examination. I removed a fairly large section, and afterwards a second section, and then rasped the edges. He recovered without a bad symptom. The remarkable feature in his case now developed itself. Shortly after he recovered he told me he had no recollection of anything that had occurred from the day he was struck on the head until the day he was operated upon. I took every precaution to prevent any imposition, but he appeared to show no disposition to deceive me. When he first became conscious, after the removal of the bone, his impression was that a short time before he had been struck on the head. He had no recollection of his marriage. He had bought a small farm, and partially paid for it, but he would not believe it until he had examined the records for himself. He appears now to be in perfect health."

Dr. Frank C. Wilson, of Louisville, reported two cases of tracheotomy, the result in one being successful, the patient, a little boy of about four years, being present in person. In November, 1881, Dr. Wilson was roused at night to see the little fellow, who had some time previously been taken sick with diphtheria invading the nasal passages. A few weeks before his brother had been attended by Dr. Senteny in the same disease. The boy's condition in the evening did not seem to demand the attention of a physician, and Dr. Senteny had not been sent for. "I explained to the father at once the dangerous character of the affection, and insisted that Dr. Senteny should be called. From that time till the operation was performed, one or the other of us was with him constantly, and endeavoring by every means in our power to stay the progress of the disease. Nothing availing, and the little fellow growing

worse, it was determined to perform the operation in the middle of the night.

"The incision was carefully and slowly made, and the hemorrhage stayed before the trachea was opened. The expulsive efforts excited by the passage of air into the opening caused renewed hemorrhage, which, however, soon ceased. A moist sponge was placed over the tube, which was cleansed about every three or four hours. The boy made a good recovery.

"The other case occurred in a younger child, and the operation was delayed until the last moment. In this case the child lived three days after the operation, and seemed to die as the result of accumulations of mucus in the trachea and bronchial tubes."

Dr. Wilson also exhibited an apparatus which he had designed to warm the air before its passage into the tube.

Dr. Pinkney Thompson reported two cases of recovery from the operation, in each of which no tube had been used. Other cases in which it had been used had resulted unsuccessfully. He regarded the tube as harmful rather than efficacious, looking upon it as a foreign body, in a delicate situation, and in itself sufficient to produce harmful irritation.

Dr. Dunlap spoke of two cases operated upon by the late Dr. John D. Jackson, both of whom recovered. He used the tube in both cases.

Dr. Yandell, D. W., reported a case in which the tube had been worn for a period of seven years.

Dr. J. M. Matthews, of Louisville, read a paper on the subject of "Hemorrhage from the Rectum—Its Causes and Treatment." This paper had reference not to ordinary hemorrhage from the rectum, such as that which accompanies almost all disorders incident to the part, and is but an accompaniment or symptom, nor to that which follows the usual operations for piles, fistula, etc., but rather to consider that hemorrhage which requires surgical interference, and which if let alone would endanger the life of the patient. After giving an explicit description of the arterial and venous distribution of vessels in this situation, Dr. Matthews said: "I have been thus careful in my remarks concerning the blood supply, not only to impress the great necessity of caution in operating, but to show how very natural it is that bleeding should occur from the part from very simple causes, it may be such as the passage of hard feces, etc., etc., and because the works on surgery devote but little space to the subject. Indeed, the rules laid down for the management of such conditions are not at all explicit. An experience of a number of years in the special practice has taught me that not only do these dangerous cases of hemorrhage from the rectum often occur, but they are mistaken for symptoms of other diseases. The causes of hemorrhage here, excluding that which results from operative procedures, may be briefly told as follows:

- "(1) From ulceration of the bowel.
- "(2) From capillary hemorrhoids.
- "(3) From the hemorrhagic diathesis.
- "(4) From polypi.

"These in my opinion constitute the only causes of hemorrhage requiring surgical interference.

"Hemorrhage from ulceration. I use the term 'ulceration,' believing it to be an *ill* term, and

that it should not be used in this connection. Yet the authors have failed to give us a better one. True ulceration is not and cannot be accompanied by much bleeding, for the reason that there is sufficient inflammatory action present incident to the process to clog the vessels, and hence to prevent hemorrhage. The condition to which I wish to direct your attention in contradistinction to ulceration is an abrasion sometimes formed in the epithelium of the gut. This may arise from trivial causes, as the passage of hard feces, etc. The result may cause serious alarm. No inflammation attending this 'peeling off,' in its incipency the blood pours freely from the capillary structures unless active measures are taken to suppress it. The discharge may be pure blood or it may be mixed with mucus. Very many of these cases have, I am sure, been mistaken for other affections, notably dysentery.

"*Treatment.*—The object of treatment in cases of this nature is of course to produce sufficient inflammatory action to clog the vessels with lymph. The very best application to accomplish this object, is in my opinion pure carbolic acid. It should be applied not only to the abrasion proper but to the mucous membrane surrounding it. It stops hemorrhage and does not destroy the membrane. Nitric acid or the acid nitrate of mercury would likely accomplish the same purpose, but at the risk of producing stricture. It would be inconvenient to apply the actual cautery. No account of the affection of which I am speaking is given in the works on surgery or in the books devoted to diseases of the rectum. Unique they may not be, but they certainly deserve more attention than they receive.

"*Hemorrhage from Capillary Piles.*—It will be remembered this is the small, spongy, raspberry-looking pile which is often met with, possessing a disposition to bleed upon the slightest provocation. The blood lost is usually arterial. A hard stool or straining at stool is a common cause of rupture, and the amount of blood sometimes lost is enormous, and may cause a fatal termination.

"*Treatment.*—I regard it best to catch up the entire bleeding spongy mass and secure it by a silk ligature. The ordinary tenaculum forceps used in ligaturing piles are objectionable in these cases. They tear through the mass and cause fresh bleeding, besides they do not enable you to secure the mass with ease. A forceps with serrated edge instead of forks on the handle at an angle of 45 degrees, I have had made by Adolph Fisher of this city, answers the purpose better. In many cases I have stopped the bleeding by the application of pure nitric or carbolic acid. The actual cautery here is a most excellent measure, in the form of thermo-cautery.

"*Hemorrhage from a Hemorrhagic Diathesis.*—This is scarcely mentioned by the authors. That it occurs has been evidenced in my practice, and when met with, it is of the most serious nature. Local measures seem to do but little good, and it is to be questioned if such patients are ever fully relieved. The diathesis is manifested in the rectum as in all portions of the body. The slightest scratch or abrasion on handling the part is sufficient cause for the hemorrhage, which is often uncontrollable.

"*Treatment.*—This diathesis may be hereditary, or it may be established by habit. Sedentary life

conduces much to its production. The habits should be carefully inquired into, and a change, if necessary, positively enjoined. Exercise, fresh air, proper diet, etc., should be carefully looked after. The sheet anchor in the treatment, I believe to be ergot or ergotine. This should be combined with iron, and given for its full effect. The best local applications are hot water (injected), *sub-sulphate of iron*, and pure carbolic acid, each to be repeated as often as may be found necessary. The last causes I have named for hemorrhage calling for surgical interference are polypi. These tumors may be above the sphincter muscles, for a long time giving rise to no inconvenience, but all at once they may begin to bleed either from detachment or other causes. They should be brought into view, and the pedicle ligated. This is best done under an anæsthetic, and by dilating the sphincters forcibly. If hemorrhage should occur from the sloughing of the tumor, or from its being torn off, the pedicle or stump must be sought, and if it is not possible to include it in a ligature, the rectum should be plugged in the manner already described. Hemorrhage from all the sources mentioned here has frequently been met with in my practice. If a proper diagnosis is made before serious damage is done by the loss of blood, the remedies are easily applied. A thorough investigation of each and every case is necessary to determine the remedy, and if the attention of the profession has been so directed, the object of this paper has not been fruitless.

"I have met with one case of vicarious menstruation through the rectum, but such cases are very rare, and require no treatment."

Dr. Dudley S. Reynolds, of Louisville, said: "I have been much interested in the discussion of the subject of hemorrhoids and their removal by ligature, the ecraseur, and by various caustics injected into the tumor. I am not a little surprised, however, to note the diversity of opinion concerning the action of carbolic acid, injected in hemorrhoidal and polypoid growths generally, whether occurring in the rectum, nasal passages, or the cervix uteri. It seems pretty generally established that carbolic acid is at times absorbed in such quantities as to create serious constitutional trouble; that it sometimes fails to cause either sloughing or shrinkage of hemorrhoidal tumors. The injection least likely to be attended by successful results, and at the same time not entirely free from the dangers of absorption, seems to be the one most commonly spoken of. In my own practice I have had a great deal of experience in the treatment of polypoid growths by injection, and I am confident that the treatment of hemorrhoidal tumors by injection may be conducted upon much the same plan and with strikingly similar results. The official tincture of iodine may be injected without provoking more pain than follows the use of carbolic acid, and should it be absorbed or introduced directly into the veins, disastrous consequences would not likely follow, because iodine liquefies fibrinous structures. It dissolves rather than coagulates tissues. Acetic acid diluted with 25 to 50 per cent. of water may be introduced in soft flaccid polypi, and I have seen them shrink and disappear after this injection without any sloughing and without any great amount of pain beyond the

moment of injection. But it seems to me, sir, in the highly vascular fibroid growths where the tincture of iodine fails, a 20 per cent. solution of chromic acid constitutes the very best and safest of all astringent injecting fluids. In this strength it is sufficiently caustic to destroy the vitality of the tumor and cause its removal by sloughing, and if carefully performed the operation need not be followed by any damage to contiguous tissues. Warty excrescences of every kind known to me will slough promptly from the injection of this substance. Unlike the ferrated solutions as persulphate and the perchloride, the chromic acid forms instantly a coagulum which isolates the mass injected from other tissues, producing almost instantaneous death of the part injected. Of course, the injection of chromic acid cannot be practiced in all cases; but certainly in all those cases where carbolic acid injections have been thought desirable, the chromic acid or the strong tincture of iodine offer far better chances of success. In fact, my experience leads me to conclude that carbolic acid is least desirable of all injecting fluids in the treatment of polypi and other tumors."

FRIDAY MORNING.

Dr. Sargeant, of Hopkinsville, reported a case of strychnia poisoning, in which recovery occurred after the ingestion of twenty grains. The stomach was not evacuated, because the interval between ingestion and the doctor's arrival had been sufficient to render it probable that the drug had all been absorbed. "At 8 p. m. he had seven convulsions in rapid succession. At 9 p. m. I reached his bedside and found him perfectly rigid and opisthotonos complete, legs extended, feet everted, arms flexed, and fingers clinched. Jaws spasmodically closed, lips and eyelids retracted, pupils dilated, face blue, and skin bathed in a profuse perspiration. On account of the inability of the patient to swallow, he was given, per rectum, 110 grains of chloral hydrate and 120 grains of bromide of potash. At ten o'clock he was able to swallow thirty grains of chloral hydrate and sixty grains of bromide of potash. This was repeated at 11 p. m. and 12.30 a. m., when he had the last convulsion. Until 3 a. m. he complained of great muscular soreness. Another dose was given, after which he was not seen until 11 a. m. He had then eaten some breakfast, and was apparently as well as ever.

"The conclusions reached were as follows:

(a) Quite a long interval may intervene between the ingestion of strychnia, and its poisonous manifestations; (b) toxic doses act in a similar manner in all animals, however much the susceptibility may vary; (c) the muscular rigidity disappears first in point of time, (1) from the jaw and muscles of deglutition, (2) from the legs and arms, (3) from the spinal column, and (4) from the muscles of respiration; (d) death results from asphyxia; (e) chloral hydrate and bromide of potash are antagonistic to strychnia."

Dr. W. C. Webb, of Bryantsville, read a paper on "Pertussis." In the treatment of this disease, though opposed to the doctrine, Dr. Webb looks upon croton-chloral, when properly administered, as a specific. The dose for a child one year old is one grain every four hours, from six to twelve two grains, but adults seldom can stand more than four grains. It should be given regu-

larly at stated intervals; at first both night and day, at the end of a week only in the day.

Dr. John A. Ochterlony, of Louisville, made the report of the Committee on Dermatology. Very briefly, the author remarked upon the steady increase of knowledge concerning skin affections, made by microscopical investigations; citing first the discovery of a fungus by A. Von Hebra, which has hitherto escaped detection; it is quite small, seldom rod-shaped, has no organs of fructification, is symmetrical in its distribution on the neck, bend of the elbows, and popliteal spaces. The affection it produces is likely to be mistaken for eczema. It does not affect the hairs, does not occur in rings, and runs a very chronic course. It must first be subdued by soothing applications, and afterwards treated by parasitocides. Emile Vidal describes a "microscopon dispar" found in pityriasis circinata et marginata; their characteristics are diminutive size, variation in volume, circular arrangement, scarcity of chains of spores, and absence or great rarity of mycelium. It never has been known to occur in a person past forty years of age; affects the face and beard, but not the hair follicles; does not appear to be contagious, and is speedily removed by means of the usual antiparasitic remedies. That leprosy is a disease of parasitic nature has been clearly demonstrated.

The writer referred to an article by Sarah E. Post, M. D., entitled "Cutaneous Irritation," in the *New York Record*, showing the effect upon the pulse of general cutaneous faradization. No application of the results arrived at was made, however. The author discussed the subject of isolation after attacks of contagious eruptive fevers. For small-pox, scarlet fever, measles, and diphtheria, isolation should not be shorter than forty days, and for chicken-pox twenty-five. The patient should be thoroughly bathed, and the clothing worn subjected to a temperature of 194° F., and to sulphur vapor.

Professional opinion still remains divided as to the effect of malarial miasm in the production of acute diseases of the skin. Herpes, however, is regarded by Verneuil and Meklen as one of the common manifestations of malarial poisoning.

The therapeutics of diseases of the skin have been enriched by various new remedies, perhaps the most important of which is naphthol. Its most favorable effects in the hands of the writer have been secured in scabies. No preparatory treatment has been required. It does not soil the clothes, causes no irritation of the healthy skin, and a single application is sufficient to effect a cure. The following is the formula given by Kaposi:

R.	Axangiae vel unguenti mollis,	100 parts.
	Saponis viridis,	50 "
	Naphthol,	15 "
	Cretae preparatae,	10 "

In children, the naphthol may be reduced to 10 parts.

Rub the ointment briskly into the parts, powder starch over the surface, wrap the patient in flannel, and a cure results in 24 hours.

The author spoke highly also of the various oleates, which have proved themselves worthy of continued favor at the hands of the profession. Boracic acid, salicylate of soda, and powdered er-

got, were each highly extolled. Immersion in hot water of the affected parts to relieve the intense itching accompanying certain skin affections was warmly spoken of. By this means a good night's sleep may be secured to a patient who would otherwise have to endure many hours of most uncomfortable unrest.

Dr. W. H. Wathen, of Louisville, exhibited a case of curved hollow needles, consisting of five, made to fit in one handle, each constructed for the purpose of introducing silver sutures. The instrument is adapted particularly to operations upon the perineum, vagina, and cervix uteri, as well as in laparotomy. The whole case resembles somewhat those manufactured by Tiemann and Sherer, but differs in that the needles can be much more expeditiously changed when such changes are necessary in the course of an operation. Advantage is also gained by the curve of the needles, which resemble somewhat "half-of-the-first-curve-of-a-corkscrew," enabling the operator to reach parts which would otherwise be inaccessible.

PROCEEDINGS OF "THE COLLEGE OF PHYSICIANS OF PHILADELPHIA."

Sewer Gas, and its Alleged Causation of Typhoid Fever.

BY GEORGE HAMILTON, M. D.

[Read March 7, 1883.]

(Continued from page 429.)

Trousseau did not rashly, as often happens, declare his opinions on this point. His opportunities for the study of typhoid fever in Paris were abundant, yet he was not satisfied with these, knowing, as he did, that the rural practitioner, having personal intercourse with nearly every family within a limited range, and consequently having superior advantages for observing the first outbreak and the progress of disease, would be most capable of arriving at a knowledge of its origin, whether from local or general agencies, or from contagion. To this source of information he often resorted, either by letter or personal interviews; and endowed, as he was, with an eloquence brilliant and comprehensive, a marvellous power of observation, and logical acumen, it is not strange that in life he was, and yet remains, in the first rank of philosophic medical authorities.

In illustration of the above statement, my own experience may here be alluded to. Leaving Philadelphia in the autumn of 1834, a location was chosen at a distance of thirty miles from the city, between Wilmington and Kennett Square, seven miles distant from either, and about eleven from West Chester. The surrounding country was hilly, abounding in springs of fine water. Bilious remittent and intermittent fevers prevailed at this time, and for a few years after, in Philadelphia, to an extent that has not since occurred. The remittent form only held possession of this rural section, and before the frost of November put an end to the disease, as it always did, the statement of Dr. Joseph Parrish in regard to its prevalence and fatality in the country was fully confirmed in my own experience. After five or six years, bilious remittent was supplanted

by typhoid fever, and it would be inexcusable did the writer neglect to cite two or three instances of this malady, of marked importance in relation to its origin and development. A wealthy farmer had sent a son on business into Maryland, forty miles from his residence. After an absence of several weeks he was brought home affected with typhoid fever, and, in succession, the father, two other sons, two daughters, and a colored servant, were attacked, all severely, except the servant, the mother alone escaping the disease. An attendance lasting nearly four months was required, and, although three of the patients were in great danger, all recovered. In another family of seven persons, four were prostrated; one, a young man of eighteen years, dying from perforation. In this instance, again, the disease did not originate on the premises. The mother, the first attacked, had been absent from home assisting to nurse a relative, at a distance of several miles from her own residence, to which she was brought unwell, and thus communicated the disease to the others. Many physicians, perhaps all professed sanitarians, are in the habit of expatiating upon the great and unnecessary prevalence of what they call filth diseases—typhoid fever, scarlet fever, and diphtheria, in the large cities—and seem indisposed to turn their attention to the country until reminded, from time to time, of the ravages of these same diseases in rural sections, greatly exceeding, in proportionate number of cases, violence, and fatality, what is to be found in cities. Yet the sanitarian, or the inexperienced practitioner, fertile in expedients, soon discovers the sources of their origin in decomposed vegetable matters in cellars and elsewhere, or in water and milk contaminated by the requisite family outhouse; while the attending physician, though upon the spot, cannot, unless in exceptional cases, find any rational ground for these necessitated conjectures.

But, in this connection, let us revert to the condition of agriculture and husbandry in regard to household, dairy, and stable economy half a century ago. At this period, agricultural journals, or other works pertaining to those subjects, were scarcely known; whilst, for many years past, they have been disseminated over the land, throwing a flood of light upon all that concerns agriculture and husbandry, the good effects of which are now visible on every side. It might here rationally be asked, What was the state of the country at the early period named, and was there not much more typhoid fever than has since occurred? On the contrary, typhoid fever, and also diphtheria, were almost unknown at that time, while bilious remittent, not generally regarded as a filth disease, prevailed, and so continued until about five years before the return of the writer to Philadelphia in 1845. As before intimated, a sharp frost or two would arrest the progress of bilious fever; not so in regard to typhoid—on the contrary, one of the worst invasions of the disease continued throughout the winter and early spring, and this peculiar and important feature finds its counterpart, not seldom, in this and other cities, where, independent of the agencies of warmth and moisture in promoting the decomposition of animal and vegetable matters, and evolution of gas, the disease has prevailed in an aggravated form.

In the writer's experience it did not often happen that either typhoid or remittent fever prevailed extensively in two consecutive years. In this respect it resembled dysentery, raging with a fatality this year unseen in the city, whilst during the following season very few cases would appear—the local conditions in either case presenting no perceptible change.

An important point in the history of typhoid fever, as it occurred in the country, was, that if the disease once appeared in a farm-house, it would, as a rule, attack more than one of the members of the family before leaving it, and this, too, when the physician knew of no other case within a mile or more of the afflicted family. Now this is in entire accord with the admitted contagiousness, under certain conditions, of typhoid fever, not only by Trousseau, but by a majority of the most distinguished writers, among them that pre-eminent author and teacher, Austin Flint, Sr. The feature just noticed does not, as a rule, occur in the city, for in an immense majority of cases there will be but one member of a family attacked. Now it has been said by a somewhat noted medical statistician, and concurred in by many others, that if a case of typhoid fever appears in a family, it proves the existence of gas or filth in immediate relation with the residence. This is certainly explicit; but the question is, how happens it that, with such an efficient cause for the first case, it is only

occasionally followed by others in the family? But, again, it may be asked, if sewer gas—for this, after all, appears to be the great "*cheval de bataille*"—has not been, and is not yet excluded by even the best plumbing, from the finest houses in this city or New York, and, consequently, that tens of thousands of houses in both cities are in this fearfully exposed condition, how comes it that in Philadelphia, with 900,000 inhabitants, the Board of Health has recently reported but two deaths from typhoid fever in one week, and four in another; whilst diphtheria, said to be due to the same agencies, has prevailed at the same time to an alarming extent? The returns of the Board of Health of New York present similar statistics, showing comparatively fewer deaths from typhoid fever than Philadelphia, but a larger proportionate fatality from diphtheria and scarlet fever. That many physicians neglect to carefully examine these reports is well known, and yet they are the only available and reliable sources of information in regard to the character and movement of disease. If, instead of this reprehensible neglect, a diligent and discriminating examination were regularly made, it would do much to prevent misconception and error in regard to the actual causation of disease, a subject admitted by the most experienced and gifted minds to be one of equal difficulty and importance.

(To be continued.)

EDITORIAL DEPARTMENT.

PERISCOPE.

Inheritance of Cancer.

The *Brit. Med. Jour.* says:

In the course of a paper on the Local Origin of Malignant Growths, read in the Section of Pathology at the last annual meeting of the British Medical Association, Mr. Jonathan Hutchinson observed: "It is useful to say a few words as to the inheritance of cancer in its bearings upon the doctrine of its local origin, since an adverse argument has been founded upon it. It has been urged with much plausibility that a disease which is capable of inheritance must be a constitutional one. No doubt, to some extent, this is true; but the argument must not be pushed beyond its legitimate scope. The laws of inheritance, as with property, so with disease, concern convection, and not origin or production. The inheritance of a fortune is a very different thing from its acquisition, and gives us no clue as to how that may have been accomplished. The causes of cancer, as we meet with it in practice, may, perhaps, be usefully classed as three: senility of tissue, local irritation, and inheritance. Of these, only the first two can rank as true causes; the latter, although practically of great importance, is only a mode of perpetuation of that which the other

two have originated. Senility gives proclivity, local irritation excites, and subsequently hereditary transmission may perpetuate. The facts, as regards chimney-sweepers' cancer, give perhaps the best illustration of what I mean. Before this malady was practically suppressed by Act of Parliament, I believe it was commonly noted that when the trade of sweep went, as it often did, in a family, proneness to suffer from soot-warts, and for soot-warts to degenerate into cancer, increased in successive generations. Grandsons and great-grandsons were attacked at earlier ages, and with much greater frequency, than those who were new to the trade. Here, then, we observe the liability to a form of cancer, produced in the first instance by a local cause, perpetuated and intensified by hereditary transmission. We witness the genesis of cancer, and see the shares taken by local irritation and inheritance, and how entirely secondary the latter is as regards the former. If we ask what it is which is inherited in the case of the transmission of cancer, probably the nearest approach to an answer which can be given will be to say that it is a peculiarity in cell-structure generally; not germs, not a blood-malady, but a special type of cell organization, permitting, with greater ease than in other persons, the injurious influence of local causes. Even in the

sweep, whose forefathers have suffered from soot cancer, the transmitted tendency still waits for the exciting cause; and the disease occurs, not in internal, and, therefore, protected parts, but on the same part as it did in his great-grandfather, and under the direct influence of exactly the same cause. Not that I would for one moment doubt that, in some instances, the inherited proclivity may be so strong that it does not wait for the help of any exciting causes, but manifests its power in the production of a cancer which may be considered spontaneous. It is probable in this way that we ought to explain almost all cases of cancer occurring in very early life; and it may be a fact that, in a few of these, something more definite than mere tissue proclivity may be transmitted; possibly even germinal matter, especially in those cases in which the parent was the subject of the malady. Thus, then, although I fully admit that in the examination of our patients we must make large allowance for the influence of inheritance, I wholly deny that we can allow it to rank as a true cause of cancer."

The Treatment of Spermatorrhœa.

Dr. H. Coupland Taylor thus sensibly writes in the *Brit. Med. Jour.*, March 24, 1883:

Obstinate cases of spermatorrhœa and frequent nocturnal emissions constantly come under the care of the practitioner. Too frequently the medical man consulted simply tells the patient that, if he break off the pernicious habit of masturbation, which has probably originated his malady, he will soon quickly recover. But in fact, in most cases, the habit has already been abandoned before he comes to seek advice; and these cases do not get well for months or even years afterwards, unless proper measures be taken. Knowing that he has left off this bad habit, and that he nevertheless does not improve, his complaint being made light of by the regular practitioner, and being greatly depressed in mind, he seeks the advice of the quack, who is always ready to benefit by these cases. I will give an outline of the treatment I have followed, and which I have found most successful in several such cases. The treatment should be: 1. Moral; 2. Hygienic; 3. Medicinal. 1. *Moral.* *a.* The pernicious habit of masturbation, which has probably been the origin of the complaint, must at once be discontinued, or no good can result from any treatment. *b.* The thoughts should be directed from himself by his having regular work and exercise. *c.* The anxiety of mind which ensues should be allayed as much as possible, and a happy state of mind instituted. 2. *Hygienic.* *a.* The patient should have regular but not excessive mental employment, and bodily exercise in the form of walking, riding, or outdoor sports and games. *b.* Cold sponging of the genitals night and morning for some minutes, or as long as can comfortably be borne, is a most important agent in giving tone to the relaxed organs. *c.* The patient should have a hard mattress, and as little and as light clothing as possible at night. Care should be taken not to lie on the back, which may be prevented by wearing a knotted towel over the spine, or by some other device. *d.* No quantity of liquid should be taken before retiring to rest, and the bladder should be

emptied the last thing. 3. *Medicinal.* A mixture containing tincture of perchloride of iron and tincture of nux vomica should be given twice or three times a day: also a pill containing a fourth or a third of a grain of extract of belladonna with three grains of camphor should be given at first every night, and then every other night, immediately before going to bed. If these lines of treatment be adhered to, the patient, whether suffering from real spermatorrhœa or simply from frequently returning nocturnal emissions, will steadily improve, and the emission will occur less and less frequently, till, in the course of a few weeks, or possibly months—for a malady of long standing (as this usually is) is never cured immediately—they will cease altogether, or only occur at such intervals as may be deemed normal, and in which there is no harm whatever.

Sulphurous Acid in Scarlatina Maligna.

In the *British Medical Journal* Dr. Keith Norman Macdonald, after denying the prevalent opinion, that no reliance can be placed on any drug in cases of scarlatina, does not hesitate in affirming that, when properly applied, both locally and internally, sulphurous acid is by far the most efficacious remedy we possess. He continues: "I have had several opportunities of testing its efficacy in some of the worst cases I have ever seen, during the epidemic which has been rife in this town (Cupar Fife) for the last two months, and I am bound to say that, of all remedial measures in this disease, it is, in my opinion, the most reliable. My treatment is as follows: The moment the throat begins to become affected, I administer to a child, say of about six years of age, ten minims of the sulphurous acid, with a small quantity of glycerine in water, every two hours, and I direct the sulphurous acid spray to be applied every three hours to the fauces for a few minutes at a time, by using the pure acid in severe cases, or equal parts of the acid and water, according to the severity of the case. Sulphur should also be burned in the sick chamber half a dozen times a day, by placing flour of sulphur upon a red-hot cinder, and diffusing the sulphurous acid vapor through the room, until the atmosphere begins to become unpleasant to breathe.

"In the worst cases, where medicine cannot be swallowed, this and the spray must be entirely relied upon; and the dark shades which collect upon the teeth and lips should be frequently laved with a solution of the liquor potass permanganatis of the strength of about one drachm to six ounces of water, some of which should be swallowed, if possible.

"In cases presenting a diphtheritic character, the tincture of perchloride of iron should be administered in rather large doses in a separate mixture with chlorate of potash, and equal parts of the same with glycerine should be applied locally, with a camel's hair brush, several times in a day; but, as in the majority of cases among children it is next to impossible to use a local application more than once; the spray and permanganate solution will then prove of great service.

"As to other remedies recommended by various authors, ammonia is nasty, and cannot be taken well by children; carbolic acid has the same

fault, and cannot be applied properly. Gargles are also useless in children, because they seldom reach the diseased surfaces, and warm baths and wet sheet packing are dangerous, because they are never carried out properly in private practice. The hypodermic injection of pilocarpine is a remedy that may give good results hereafter, but I have had no experience of its use."

Spontaneous Uterine Contractions.

From the *Lancet*, March 3, 1883, we learn that an extensive series of experiments on the occurrence of spontaneous uterine contractions in the mammalia has been made by M. Dembo, who has communicated an account of his observations to the Académie des Sciences. The observations were made upon 123 animals, and lead to the following conclusions: There are, strictly speaking, no spontaneous contractions of the uterus, but the organ may be readily made to contract by different agents, and the movements which have been regarded as spontaneous are really excited by extraneous influences. The gravid uterus may be made to contract much more readily than the unimpregnated organ, especially under the influence of thermic excitation. In the cow, when one uterine cornu is alone gravid, this contracts much more energetically than the other under the influence of the same stimulation. If the abdomen of an animal is opened with great care, in a room properly warmed, it is extremely rare to see any contractions. If the uterus, or the vesical wall of the vagina, is stimulated by electrical, mechanical, thermic, or chemical agents, the effects observed are as follows: The effect of chemical stimulation of the uterus is almost *nil*. If chronic, nitric, or acetic acid is applied to the wall of the vagina, contractions of the uterus are rarely produced. Mechanical excitation, however, is a powerful stimulant of uterine contractions, whether the uterus is in its normal connections or has been previously separated from the body. Thermic influences, cold and heat, have a powerful effect on the uterus of all animals, and the degree of excitation is in proportion to the difference between the temperature of the uterus, and of the air of the chamber. This thermic excitability increases during pregnancy. Dembo has succeeded in causing the expulsion of a fœtus from the uterus of a rabbit by plunging it into a bath of 45° C., while the strongest faradization failed to produce the same result. As an illustration of the influence of temperature, and the erroneous conclusions to which it has given rise regarding the occurrence of spontaneous contractions, Dembo mentions that such contractions are frequently observed in a rather cool laboratory at Paris, while on a repetition of the observations in the well-warmed laboratory of Stricker, at Vienna, no contractions could be observed, and in a cold slaughter-house the contractions were most energetic and persistent. These observations throw great doubt on the conclusions of Trommell, who has lately demonstrated, as he believes, the occurrence of spontaneous contractions by introducing a tube, and registering the movements by a hæmo-dynamometer. It seems probable that the contractions registered were not spontaneous, but were produced by the mechanical irritation of the tube or of the liquid employed.

Sudden Changes in Color of Hair and Skin.

Before the Academy of Medicine in Ireland (*Med Times and Gaz.*, March 24, 1883).

Dr. H. J. Smyly read a paper on sudden change in the color of the hair of an infant. The child was perfectly healthy to all appearance until he was four months old. He was then attacked with acute inflammation, followed by suppuration, in the left temporal bone, the symptoms being pain, heat, and swelling about the temporal region, with high fever and profuse perspiration; paralysis of the left side of the face (with lagophthalmos) and of the soft palate. One morning in November last the hair on the right side of the head was discovered to have undergone a remarkable change from its original mouse-colored hue to a reddish-yellow. The right eyebrow was similarly affected, and the skin of these parts, as well as that of the right hand, was icteric. The pillow also was saturated with a reddish-yellow perspiration. The abscess, which had formed very slowly, pointed behind the ear, and was evacuated by a free incision. Although the child subsequently became hemiplegic, it made a fairly good recovery. The suggestion offered as to the possible cause in this remarkable change of the color of the hair was that the perspiration, which was of a peculiar color, and probably of abnormal chemical constitution, not only destroyed the original pigment, but also dyed the hair a reddish-yellow color.

Dr. Banks referred to a case which had come under his notice—that of a young woman. Half of the lashes of one of her eyes became snow-white, which she attributed to the annoyance suffered from the persistent gaze of a "wall-eyed" admirer who had white lashes on the defective eye.

Dr. Walter Smith related the case of a boy in whom the skin of the lobes of both ears and that of the back of the neck was of a sulphur yellow, the downy hairs being of a bright yellow, while the hair of the head was brown. The yellow coloring could be readily removed by a moistened cloth, but no washing could decolorize the skin, nor did ether or chloroform produce any effect. He exhibited specimens of the hair. He also referred to a case of red discoloration recorded by Wilson. After relating the case described by Darwin—in which the hair of a criminal brought out for execution turned white in the presence of the spectators—he said he could not agree with Dr. Smyly in ascribing bleaching properties to the perspiration, but did not give any explanation in lieu of it.

The Experience of a Vegetarian.

Dr. T. R. Allison thus records his experience in the *Brit. Med. Jour.*, March 3, 1883:

Last year, about this time, I determined to see how I got on if I abstained from the use of animal food. A year has now elapsed since I have touched fish, flesh, or fowl. When I first started I did not feel that satisfaction which one feels after a flesh meal, and the vegetables tasted insipid; in fact, I had to use sauces and pickles to get them down. Time gradually used me to my diet, and now I can eat them just as they are cooked. I have lost all desire for the condiments,

such as sauces, pickles, spices, mustard, and pepper; salt I use in small quantity. My taste for alcoholic liquors has also gone, and, with it, my liking for tobacco. I was costive as a rule until I took to vegetable diet, and, during my trial, I have been constipated only once. For the period of a month I was traveling, and could not get my brown bread, and so my bowels did not act so well; but a return to my whole meal bread soon cured that. I am fond of mental work, and I find that I can do more work on it than on a mixed diet. I have not had a bilious attack or sick headache since taking to it. Rheumatic pains fitted about my joints, and I was afraid of rheumatic arthritis setting in; but three months sufficed to rid me of these. My urine used to be loaded with lithates, but the sediment went in a fortnight's time, and I have not seen a deposit since. My renal secretion often has a sweetish smell, and sometimes a smell of roast meat. There has been no decrease in my bodily powers, and I can run and take exercise as well as ever. I have gained seven pounds in weight during my experiment. My senses are acuter, especially those of taste and smell. My sexual passion has moderated, and is not so violent as on a mixed diet. I have a good flow of animal spirits, and am very rarely depressed. I do not eat more food on my new diet than I did as a mixed feeder. Breakfast consists of brown bread, apples, and a cup of coffee; in summer, I have lettuce instead of apples. Dinner is usually composed of two vegetables, brown bread, and a pie or pudding. For tea, I have a cup of milk and water, bread, and jam. Supper, when taken, is bread and jam, cold pudding, or boiled onions. Eggs, milk, butter, and cheese, I use only in moderate quantities.

Occlusion of the Inferior Vena Cava.

Before the Academy of Medicine in Ireland (*Med. Press*, March 21, 1883).

Dr. F. W. Warren read a paper on the subject of occlusion of the inferior vena cava, illustrating his remarks with a rare case in which the inferior cava was completely occluded by a calcareous tumor, about the size of a bean, growing by a narrow pedicle from the great Eustachian valve. The tumor completely obstructed the vein at the caval opening of the diaphragm, and was adherent to the lining membrane of the vein. The specimen was taken from the body of a male, æt. twenty-two. During life, both lower limbs, the front of the abdomen and the anterior aspect of the thorax, were covered with a close network of varicose veins—the head, neck, and upper extremities being perfectly normal in appearance. The patient stated he had these enlarged veins as long as he could remember. He was otherwise perfectly healthy, there being no œdema, no hemorrhoids, no albuminuria; but he died unexpectedly of enteric fever from perforative peritonitis, and he suffered from œdema of the liver from the onset of the fever. A careful post-mortem examination having been made, the principal channels of collateral circulation were as follows: The vena was about the size of the latter vein in health; the superficial compensatory circulation was principally carried on by the superficial deep epigas-

tric veins, with the circumflex iliac veins from below anastomosing with the internal mammary and long thoracic veins from above, the source of blood current being reversed and passing from below upwards. Within the cava, just as it opened into the right auricle, the tumor already described was discerned. The venæ cavæ hepaticæ were not obstructed, as a surgical probe could be passed through them into the right auricle. Dr. Warren was of opinion that the tumor commenced as a fibrinous vegetation upon the great Eustachian valve, and then underwent calcareous degeneration, causing very gradual and finally complete obstruction of the cava. Upon striking the tumor with a pencil or spatula, its stony and calcareous character was readily demonstrated. The tumor did not in any way partake of the character of a thrombus, as it was round, small, isolated, and attached by a narrow pedicle to the valve. Dr. Warren was also of opinion that the tumor was intra-venous altogether in its origin and development.

Transfusion of Saline Solutions in Acute Anæmia.

M. Schwarz, in a memoir published in the *Berl. Klin. Woch.*, No. 40, 1882, arrives at the following conclusions after a very careful study of the subject:

Death, when ensuing on hemorrhage, is due principally to cessation of the circulation, and this sudden stoppage is due to the simple disproportion between the size of the vessels and their contents, and not to an exaggerated diminution of the quantity of blood corpuscles.

The first indication then will naturally be to remedy this disproportion.

If ordinary means fail, recourse may be had to a very innocent method, yet one that has proven extremely sure and active; this is direct injection of feeble alkaline solutions (6 per cent.) of chloride of sodium into the circulatory system. The action of this transfusion on cardiac activity, blood pressure, respiration, and all the other vital functions, has shown itself with surprising rapidity in rabbits and dogs who had lost from one-half to two-thirds of the entire quantity of blood contained in the body. The minimum quantity of liquid to be injected in the adult should be about five hundred cubic centimeters. This species of transfusion is also indicated in the serious collapse coming on during operations on the abdomen. Since the above conclusion appeared in the inaugural thesis of the author, five cases of transfusion of chloride of sodium solutions have been reported by Bischoff, Küstner, Kocher and Kümmel.

Mr. Schwarz himself reports the following case: After an operation for the removal of uterine cancer, violent hemorrhage occurred. The woman lost consciousness, the face was cold, skin dry, pupils insensible, heart-beats feeble. One thousand cubic centimeters of solution of table salt was injected into the median vein. The result was prompt and favorable.

Capillary Puncture of the Stomach for the Injection of Liquids.

The *London Med. Record*, February 15, 1883, says that Dr. Iginio Tansini, of Lodi (*Gazz. degli*

Ospitali, August 16), proposes this operation as likely to be often of great service, especially where passing the œsophageal tube is impossible or unadvisable, and where antidotes have to be promptly introduced into the stomach. Gastrotomy is always a serious operation, while puncture by a capillary trocar he has proved by experiments on animals to be harmless. From his studies on the dead body he believes that it is practicable, even with the stomach empty and retracted. Labbé says that the anterior surface of the empty stomach is directly accessible in a triangular space, whose base is below and corresponds to the great curvature (or to the transverse line which joins the cartilages of the ninth ribs); and whose margins are: to the right, the left lobe of the liver; and to the left, the margin of the false ribs. Tansini introduces the trocar about $6\frac{1}{2}$ centimètres from the xiphoid apophysis on the left, near the costal margin, the trocar being directed slightly towards the diaphragm. For greater security, when the stomach is pushed against the diaphragm, he introduced the trocar in the eighth left intercostal space, close to the sternum. He owns that the introduction of a trocar through the abdominal and intercostal parietes into an empty stomach is uncertain; the risk is run of either not penetrating the stomach at all, or of penetrating too deeply. He therefore recommends an incision to be made 3 centimètres along the left costal margin, the centre of the incision to be about $6\frac{1}{2}$ centimètres from the xiphoid apophysis. Thus the anterior surface of the stomach may be exposed and seen to be uncovered by the left lobe of the liver and colon, and if this last be in the way it may be pushed down, and the trocar then introduced.

REVIEWS AND BOOK NOTICES.

BOOK NOTICES.

An Introduction to the Study of Organic Chemistry. By Adolph Primer, Ph. D. Translated and Revised from the fifth German edition by Peter T. Austin, Ph. D., F.R.C.S., etc. New York: John Wiley & Sons, 1883, clo., 8vo., pp. 403. Price \$2.50.

Organic chemistry is a confessedly difficult branch for beginners, and Dr. Austin, in translating this clear and well-arranged text-book, has done a good service to the cause of chemical science. The author is Professor of Chemistry in the University of Berlin, and as a practical instructor of long experience, he knows just how to present the difficulties of his subject in such a way that they will be the least formidable to students. The translator, as he tells us, has preserved the easy lecture style of the original, and has also introduced the more important recent discoveries in organic chemistry.

The manufacture of the volume is satisfactory

in all respects, and the excellently-arranged and full table of contents and index merit great praise, and are examples of what all scientific works should be provided with.

First Annual Report of the State Board of Health of Indiana. 1883.

Sixth Annual Report of the Board of Health of the State of New Jersey. 1882.

The Indiana Board presents an interesting volume both for those in and out of the State. Of the special articles it contains, we may mention one by Dr. Lomax on the epidemic, endemic, and contagious diseases in the State in 1882; on sewers and drainage, by Dr. J. W. Compton; the Relation of Sanitation to Christianity, by Dr. Geo. L. Curtis; on the Adulteration of Food, by Dr. W. W. Vinnedge; on the surface geology, topography, and sanitary survey of Indiana, by Dr. Thad. M. Stevens, the efficient Secretary of the Board, and various statistical tables.

The New Jersey report discusses such subjects as the disposal of town and city sewage; small-pox and vaccination; health foods, invalid foods, and infant foods; local boards of health; local sanitary inspection; charitable and penal institutions, and such topics, all by competent hands and in a satisfactory manner. There are also climatological records, vital statistics, etc.

Students' Guide to Diseases of the Eye. By Edward Nettleship, F. R. C. S. Second American, from the second English edition, with a chapter on "Examination for Color Perception," by William Thomson, M. D., etc., Philadelphia. H. C. Lea's Son & Co. Clo. 8vo., pp. 416.

This manual appears to have met with as favorable a reception in America as in England, and in the present edition both the authors have endeavored to merit the continuance of its popularity by a close revision of the text. New matter has also been added, and the volume is neatly printed and fairly illustrated.

An Index of the Practice of Medicine. By Wesley M. Carpenter, M. D., etc., New York. Wm. Wood & Co., 1883, 8vo. pp. 104.

We cannot see the value or the place of this book. It is merely an abbreviation of the text-books on practice, intended apparently to be carried in the pocket, and with an inter-leaved edition for those who want to make notes. The author says that it is intended as "an aid to the practice of medicine." Any practitioner who needs it had much better take down his sign, and go to some honest means of getting his living, as he should have learned its contents before he had received his diploma.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.
Marriages, Deaths, and Personals are inserted free of charge.
All letters should be addressed, and all checks and postal orders drawn to order of
D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a quarterly, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for strictly in advance and directly to this office.

CHRONIC INVERSION OF THE UTERUS.

While occasionally seen, yet complete chronic inversion of the uterus is an affection so comparatively rare, and one about which there is so apt to be confusion in diagnosis and serious error in treatment, that it is well for all physicians to be warned, lest they may some time unwittingly amputate a uterus when they think they are only removing a polypus.

This has been done by some of the most eminent obstetricians, and would have been done recently by Dr. B. F. Clark, of Cincinnati (who reports the case in the *Cinn. Lan. and Clin.*, March 31, 1883), only, luckily, while tightening it, the wire of the ecraseur broke, and a further examination revealed inversion. Upon the first examination, Dr. Clark found a tumor one and a half inches from the vulva, movable, soft, easily indented, and not painful; vagina small, and filled with clotted blood. On October 17th, efforts were made (under anæsthetics) to reduce the uterus. No progress. The manipulations were bi-manual, per rectum and vagina, while the tumor was steadied with the hand on the abdomen. Six subsequent efforts proved nearly futile.

In the meantime the vagina was packed with carbolized tampons of glycerine and cotton. On January 25 he succeeded in making quite a depression in the fundus, and finally on the next day he crowded his finger into the depressed portion (Næggerath), brought the fundus down, and by a sudden movement upward (as suggested by Thomas) reinverted as far as he could reach. He then introduced a sperm candle, previously prepared, and carried the fundus home, as it were. No anæsthetic was used; was not longer than twenty minutes; the cavity measured two-and-a-half inches. There was a left lateral displacement, abdominal and rectal touch; the sound in the bladder proved the uterus in situ.

Dr. Clark considers the best time to make reduction is in the interval between menstruation, though in the discussion which followed the reading of his paper in the Academy of Medicine, it was contended by some that during and immediately

after the menstrual epoch the parts were more flaccid, and could be more readily reduced. The cause of the inversion was traction on an adherent placenta.

This case is instructive.

1st. In that it shows how readily an error of diagnosis may be made in these cases, and how serious might be the results; and,

2d. In that it demonstrates how much can be accomplished by patience and perseverance.

THE MICROCOCCUS OF ERYSIPELAS.

Whether worthy of it or not, so high an authority as the *British Medical Journal* gives its adherence to the claim of Fehleisen (of Berlin) assistant to Prof. Bergmann, that he has demonstrated a causative micrococcus of erysipelas.

He has found them in abundance in small portions of skin excised from the diseased part in patients suffering from erysipelas.

To prove that their presence was not merely accidental, he cultivated some small excised pieces of skin on gelatine, after having carefully disinfected the affected part, and succeeded, after two months, in producing fourteen generations, with which he produced true erysipelas in eight out of nine rabbits which he inoculated.

He also inoculated seven men with the pure and cultivated micrococci; six, after a period of incubation varying from fifteen to sixty hours, showed typical erysipelas, running the characteristic course. As he succeeded in successfully inoculating several cases after a period of a few months, it appears that if there be an immunity against a second attack of erysipelas, that immunity is, in most cases, only of short duration.

A three per cent. solution of carbolic acid stopped the growth of the micrococci after a contact of forty-five seconds, while the same effect was produced in fifteen seconds with a one per cent. solution of corrosive sublimate, which would seem to indicate these articles as excellent local applications, if the disease is really due to these micrococci. But is it? The bacterial origin of disease is a fascinating and attractive one, and unless we have a care it will run away with our

reason, as many similar theories have in the past with some of the greatest minds.

Fehleisen's experiments are very strong ones, and we shall look with interest for more on the subject.

THE PERITONEAL UTERINE SUTURE IN CÆSARIAN SECTION.

The great drawback to success in Cæsarian section has always been the gaping of the uterine wound, allowing the lochial and other discharges access to the peritoneum.

With a view to obviate this danger, the *Med. Times and Gaz.*, January 27, 1883, tells us that Dr. Leopold, of Leipzig, describes a successful case of Cæsarian section in which he adopted a new method of suture. "This method was, in principle, suggested to him by Säger—a paper by whom, 'in defence of the classical Cæsarian section,' appears in the same number. Säger's paper is largely devoted to criticising the suggestions of Kehrer, which we noticed in our number of October 14, 1882. The method of suture adopted by Leopold is based on the principle upon which ovariologists act, and at which Mr. Spencer Wells arrived by those few experiments upon animals for which he has been so much abused in anti-rvivisection pamphlets, and has so needlessly defended himself. That principle is the bringing together, in closing abdominal wounds, surfaces of peritoneum. To do this in closing the uterine wound, Dr. Leopold dissected up the peritoneum bounding the wound from the muscular tissue underneath to the extent of about one-fifth of an inch at the upper and lower angles, and rather more than one-third of an inch along the sides. Then he cut away the whole thickness of muscular tissue from which the peritoneum had been thus stripped. The freed peritoneum was then turned inward so that it covered the edges of the wound, and was united with carbolyzed silk sutures, so that the surfaces of introverted peritoneum were brought into contract. The patient, as we have said, did well. One successful case of course proves little; but, as an attempt to solve a difficult problem, this seems to us worth notice."

WAIFS OF PARIS.

After the age of sixteen years, children abandoned by their parents, or left without family, have no right to receive any aid or help from the municipal bureau de l'assistance publique at Paris. Consequently, these children form a class living without shelter, advice or instruction; sleeping under bridges or in the open fields, and depending on mendicacy or robbery for their daily bread.

These "enfants moralement abandonnés" have received particular attention during the administration of the last Director of Public Charities, M. Quentin, and through his efforts, ably seconded by M. Thulié, their condition has undergone considerable amelioration.

All such children are received and submitted to a period of probation, and those who are found already too vicious, are eliminated.

The others are either placed out to learn a trade, or are sent to one of two institutions which have been created for their benefit. One is a large farm where thirty boys are received and taught gardening, horticulture, etc.; in the other, a larger institution, about one hundred are received and taught cabinet-making, etc. The results obtained have been excellent; the boys, taken from misery and squalor, appear well contented with their lot. The expense at the farm amounted to but \$9,000 for the year, and almost \$2,000 were received for vegetables and flowers. At the other institution the boys remain four years, and after a short time earn almost enough to pay the expense incurred in their maintenance. From January 1, 1881, to June 30, 1882, 1,151 of these children were received through the police or from their parents; of this number, 178 were eliminated as already too vicious or subject to chronic disease.

SPECIAL CERTIFICATES IN STATE MEDICINE.

The question of the advisability of instituting examinations and granting special certificates of proficiency in the subject of State medicine is under consideration by the Fellows of the Royal College of Physicians of London, and its propriety is

strongly advocated by the *Medical Times and Gazette*:

Its importance cannot be overestimated, and it is a pity that our leading reform institutions of medical instruction in this country do not so consider it.

Of what use will sanitary legislation prove, unless we have educated sanitarians to carry out the enactments? And how can we have intelligent sanitarians, unless we properly educate them, which at present we do not? Our sanitary system in this country is very deficient, and it is because the people and even the profession do not thoroughly realize its importance, and the progress the science has made in the last few years. Sooner or later we must (and the sooner, the better) recognize hygiene as a *regular* branch of medicine, and teach its principles as we now do the practice of medicine and therapeutics; why delay these halcyon days?

We have referred to this subject before, and we must again repeat we will never have efficient sanitary legislation nor competent sanitary officials generally until our leading medical institutions see fit to make Hygiene a part of the regular winter curriculum, and examinations in this branch a requisite to graduation. Why does not some philanthropist immortalize his name by endowing a chair of Hygiene?

CASTOR OIL AND GLYCERINE.

Dr. William Soper claims that glycerine increases the purgative power of castor oil when given with it. A preparation combining but not mixing these two is active in teaspoonful doses.—*Lancet*.

The above is abstracted from the *Med. Record* for March 17, 1883. It is not necessary for us, here in Philadelphia, to refer to the English literature for this well-known fact, that is taught in our medical schools, and is known by the "tyro."

The following may be found in the Pharmacopœia of the Hospital of the University of Pennsylvania, and is, we believe, Prof. H. C. Wood's formula:

Mistura Olei Ricini.

NOTES AND COMMENTS.

Extirpation of the Spleen in Men and Animals.

To decide what possible danger a person incurs whose spleen is extirpated for some cause or other, Dr. D. G. Zesas (*Arch. f. klin. Chirurg.*, xxviii., p. 157) performed this operation on six rabbits, always under strict aseptic precautions, and invariably resulting favorably. The animals were killed respectively four and seventeen weeks after the operation, with the exception of one, which at the time of the writing of the report by the author, was still "alive and kicking." The post-mortem showed an enlargement of all lymphatic glands and of the liver, corresponding in size to the length of time the animal had been permitted to live; *i. e.* the longer the duration of life after the operation the greater the increase in size of these glands, and vice versa, a fact which may easily be explained, if we imagine that after the extirpation of the spleen the system endeavored to accommodate itself to the new condition, and other glands enlarged and took up the function of the lost organ. Two examinations of the blood, instituted four and eight weeks after the extirpation, showed the first time a diminution in the number of the red corpuscles, the second such a one of the white corpuscles. In conclusion, the author publishes all known cases of extirpation of the spleen in men, viz., seven on account of morbid lesion of the organ (†3) and twenty where the organ had been extirpated because in consequence of penetrating wounds of the abdomen it was found more or less outside of the abdominal cavity. Later he adds three more cases, and Dr. O. Güterbock, who refers to Zesas' experiments in the *Centrbl. f. d. Med. Wiss.*, 48, '82, page 880, adds the case of C. Martin, that also had a favorable issue.

Recurrent Hæmatinuria.

Dr. W. Jones Morris considers a case which he has had sufficiently unusual to warrant its publication in the *Brit. Med. Jour.*, March 24, 1883. In 1877, a boy aged ten, who was suffering from partial suppression, albuminuria, and slight puffiness under eyes, but with no pain in back and no evidence of derangement of the chylo-poietic viscera, was treated for suppression; but, before the kidneys returned to their normal action, he had a convulsion. A few days subsequently his urine became very dark, sp. gr. 1022, containing some granular matter, oxalates, and one or two faint granular tube casts, but no blood corpuscles. After three days a most extensive crop of pete-

chie appeared on the legs and thighs, but none on the body. After their appearance the urine began to regain its normal color. These attacks were repeated four times, at intervals of four weeks, and no medicine had any effect, until chloride of ammonium in five-grain doses four times daily was used, after which he had only one attack. In June, 1878, it is noted that he is as well as ever, and urine normal.

NOTE, January, 1883.—This lad has been in good health ever since, and follows the precarious occupation of a sailor; but, notwithstanding the inclemencies incident to his vocation, he has not had any return in any degree of the symptoms detailed.

The etiology of hæmatinuria seems wrapped in much doubt—derangement of chylo-poietic viscera, ague, changes in the blood, all being assigned as causes. The relief from the urinary symptoms upon the appearance of petechiæ would lend color to the last cause.

Treatment of Apoplexy.

At a recent meeting of the Soc. de Therapeutique (February 14), M. Guyet reported a case which provoked considerable discussion. He was called to attend a patient, whom he found in a state of coma, with marked stertorous breathing, contracture of the lower limbs, and a flaccid condition of the upper. Under these conditions he considered himself justified in bleeding, but hardly a wineglassful of blood had been taken when the patient sank into syncope and died.

In the discussion M. Dujardin-Beaumetz considered first the causation of apoplexy. It is due either to cerebral congestion, or hemorrhage, or to cerebral anæmia.

In cerebral hemorrhage or anæmia, almost impossible to distinguish in practice, and both resulting from vascular lesions, bleeding is contra-indicated. Bleeding to arrest hemorrhage should logically be pushed to dangerous syncope; otherwise it is useless.

In anæmia, bleeding is irrational, and has no influence on the vascular lesions, and the arterial obstructions which are the dominating cause in production of the derangement of cerebral circulation. In the rarer cases of sudden cerebral congestion, bleeding would perhaps be admissible.

M. Constantin Paul believes that bleeding may be of service in apoplexy, not as affecting the cerebral lesion, but as acting on the apoplectic condition, on the asphyxia and stasis of blood in the veins. He has seen the condition of such patients very markedly improved, particularly

where the apoplectic condition followed epileptic convulsions.

Chloral Hydrate as a Vesicant.

Dr. F. D. Ritter (*N. Y. Med. Jour.*, March 24, 1883) says: "Some three years ago I accidentally discovered that when powdered chloral, sprinkled upon ordinary adhesive plaster and melted by a gentle heat (not more than enough to cause the plaster to adhere to the flesh), is applied warm to the part where the blister is wanted, within three minutes a gentle heat is felt, increasing in intensity for about three minutes more till it is like a burn, then gradually easing off, until, at the end of ten minutes, the parts feel free from pain. The secondary effect is soothing; in some instances, within half an hour a second burning is felt, though not so intense as at first, nor so lasting. If, at the end of ten minutes, or as soon as pain has subsided, the plaster is taken off, the surface is found as effectually denuded as by a cantharidal plaster after six hours, though the discharge is not so great. Thus within ten minutes the work of an old-fashioned blister is accomplished; and the great advantages of the chloral plaster over the cantharidal are: 1st. Its rapidity of action, thus relieving pain, and producing the counter-irritation upon an engorged organ before the congestive action has had time to pass into more than the congestive stage; 2d. Its ease of application; 3d. It need never be taken off to have the blister dressed, but the original plaster may remain until the sore is entirely healed, and the plaster loosens and comes off of itself."

Transmission of Diphtheria from Children to Fowls.

Dr. L. Roth, of Kissengen, reports a violent outbreak of diphtheria among a barnyard of fowls, which he attributes to infection from children, some of the poison being mixed with the sweepings of the room and thrown into the yard. The *Med. Press*, March 21, 1883, commenting on this, says: "Such an observation as this is very interesting, and seems to bear out some of the statements of Herr M. Wolff in a paper 'On a Widespread Brute Mycosis.' In it he drew attention to the infectious diseases of domestic animals, which clinically and anatomically run a course exactly similar to those of human beings. He mentioned the fact that anthrax was met with in fowls, geese and ducks, and caused the same phenomena as when its habitat was the mammalia. He also mentioned another devastating mycosis prevalent amongst domestic birds, that bore a com-

plete analogy to diphtheria (*vide* Dr. Roth's observation). Yellow and white-yellow membranes were developed upon the most diverse mucous membranes, having all the characteristics of human diphtheria, so that it could not be removed without causing bleeding. A third disease that had its analogue in man was ulcerative endocarditis, that runs its course with the same valvular changes and multiple emboli in the various organs as in man.

Ulceration and Perforation of Intestines.

The medical literature of to-day contains an alarming number of reports of sudden and unexpected deaths, where the autopsy reveals ulceration and perforation of the intestine. The following case reported by Mr. Lentaigue in the *Med. Times and Gaz.*, March 24, 1883, serves as a type. A man of thirty entered the hospital on December 6th last, complaining of cough and debility. No evidence of organic disease could be found on a careful examination. Pulse and temperature were normal, and lungs sound. After a few days, feeling perfectly well, he was discharged. On December 11th, after leaving the water-closet, he was suddenly seized with symptoms of intestinal obstruction, which continued until the 14th, when his bowels were moved by enema, and he seemed better. Two days later the symptoms returned, and he died on the 19th. The ileum was found to be ulcerated in its lower part, and perforation had taken place through the floor of one of the ulcers. There were signs of peritonitis, and a large collection of purulent putrid matter. No mention is made of tubercular deposits, but it seems plausible that such deposits, undergoing ulcerative degeneration, might account for the phenomena.

Larvæ of Flies in the Human Intestine.

While as a rule no insect, properly so called, has ever been proved to take up its abode in the human alimentary canal, their presence, when they are found, being accidental, as being swallowed on a piece of meat upon which the eggs have been deposited, yet occasionally larvæ give trouble. Dr. Wacker, of Landsberg, in Bavaria, has published in the *Ärztliches Intelligenzblatt* the case of a boy aged 21 with colicky pains, fullness in epigastrium, constipation, and frequent fits of nausea and tendency to syncope, especially when in a close atmosphere, such as that of his cottage or a stable. Dr. Wacker prescribed one-eighth of a litre of Hunyadi János water, to be taken every morning on an empty stomach. On the third day

a vast mass (over two litres) of larvæ, partly alive and partly dead, was passed from the rectum. The patient at once recovered, feeling no more unpleasant symptoms, even when in a hot room. On examination, the grubs were found to be larvæ of a common dipterous insect, *Anthomyia cuniculina*, closely allied to the house-fly and blue-bottle.

Thrombosis in the Thoracic Duct.

Thrombosis in the thoracic duct has so far been observed in cases of tuberculosis only, and was then caused also by tubercles only, so that one could hardly speak of true thrombosis, though, anatomically speaking, the same lesion exists. Dr. U. Hilling has lately observed six such cases, and publishes them in Virchow's Arch. lxxxviii., p. 111. In each case there was tubercular inflammation and thrombosis in the thoracic duct, and five of them were met with in cases of general miliary tuberculosis, and in far-advanced age. In children who died of tuberculosis of the intestines, the morbid lesion just mentioned has never as yet been met with. In older persons, cheesy or tubercular foci were found only in two such cases. It seems as if the greater elasticity and vitality of the duct in young persons were obstacles to this form of thrombosis. When it does happen, the most rapid emaciation—a very natural symptom—is immediately noticed, besides the well-known peculiar sensation in the back.

A New Method of Treating Ulcers with Large and Slowly Separating Central Sloughs.

Dr. B. A. Whiteledge thus writes in the *Medical Press*, March 21, 1883: In these ulcers the slough remains frequently as a hard, white mass, very slow and tedious in separating from the subjacent tissue. There being no chance of healing while this slough remains, it should be removed. Finding the ordinary methods slow in effecting this removal, I was led to try the effect of pepsine as a dressing. I have now used it in some half-dozen cases, and with the most satisfactory results. Within a week it dissolves the slough, and leaves a granulating surface, very amenable to further treatment. My method of using it is to apply a lotion to the ulcer containing pepsine wine, mixed in varying strengths, but usually about half pepsine and half water, with a little tr. of lavender to improve its appearance.

Trephining for Insanity.

In 1863, a child was kicked by a mule, and his frontal bone crushed. He recovered with a deep depression. Thirteen years subsequently he com-

menced to suffer with pain in the wound and occasional dizziness, and four years later became subject to periodical attacks of insanity. In June, 1882, Dr. J. P. McGee, who reports the case in the *Miss. Valley Med. Monthly*, February, 1883, trephined and removed a disc of bone from the under surface of which an exostosis projected through the dura mater. The pain immediately vanished, and has not returned, and on January 29, 1883, it is noted that the attacks of insanity are growing gradually less frequent and less severe.

The opening in the skull, left by the removal of the disc, is firmly filled with osseous substance, and he has no sensation to remind him that his head was ever hurt.

Chloroform Water in Gastric Irritation.

It is well known that washing out or lavage of the stomach with liquids containing a certain proportion of alcohol is of advantage in chronic diseases of this organ, such as cancer, catarrh and dilatations.

M. Bianche, in *Lo Sperimentale*, November, 1882, recommends, to prevent fermentation, an aqueous solution of chloroform.

In three cases, one of cancer of the stomach, another of catarrhal gastritis with dilatation, and the third of chronic gastritis, he introduced daily, by means of a stomach pump, a quart of chloroform water, leaving it in the stomach from a few seconds to some minutes.

Instead of irritating the gastric mucous membrane, the chloroform solution augments the secretion of gastric juice, and even when it is absorbed is not toxic in so feeble a dose.

Two Cases of Perforation of the Œsophagus.

In *Centralb. f. d. Med. Wis.*, February 24, 1883, Klaar reports these two cases:

1. A woman, aged 32, swallowed a piece of bone, and an attempt was made to push it down into the stomach. Severe pain in left half of the chest resulted, and death occurred in a few days, with symptoms of pneumothorax. The autopsy revealed a perforation of the Œsophagus, with consecutive pleurisy and pneumothorax.

2. A man, aged 41, swallowed a small piece of wood which was enclosed in a sausage; the fragment remained in the Œsophagus, and in fourteen days death resulted from severe hemorrhage from the mouth and anus. The autopsy showed that the splinter of wood had been arrested in the Œsophagus at the level of the bifurcation of the trachea, and that one end had perforated the aorta.

Cultivation of the Soil vs. Malaria.

It would seem from the crucial test of experience that cultivation of the soil of malarious localities is not only the most influential, but really the only means of eradicating the poison. A new proof of this fact comes from the Abbey of the Tre Fontane, in the Roman Campagna. At first the monks were obliged to live within the city walls during the unhealthy season, but since the ground has come under cultivation, and, above all, since the eucalyptus globulus has been planted on a large scale in the neighborhood, the Abbey has been inhabited all the year round, and the fevers from which its inmates suffer are of a mild character, and rarely fatal, while formerly something like a fourth of the community succumbed every year.

Utero-Ovarian Disease in Insane Women.

Dr. Margaret A. Cleaves, physician to the female department of the State Lunatic Asylum at Harrisburg, thus writes in her annual report: "Briefly formulated, my conclusions are that a large proportion of women in insane hospitals have some form or another of utero-ovarian disease; that many of those under treatment make marked mental and physical improvement coincidently with the improved local condition, that in a majority of cases, however, this improvement, owing doubtless to the long standing of the combined physical and mental disorder, only reaches a certain point, beyond which it seems impossible to make further gain."

Etherization in Bright's Disease.

Since our columns have somewhat recently contained a discussion concerning the danger of using ether in cases of Bright's disease, the following will be of interest: Dr. R. Van Santvoord, of New York (*Med. Record*, March 10, 1883), has collected and analyzed all the reported cases of death from this cause, and concludes that while the recorded evidence is not *conclusive*, yet it is highly probable that structural disease of the kidneys furnishes a grave contra-indication to the administration of ether, and that the surgeon ought to be aware of the risk, and sure that the advantages to be gained more than counterbalance the danger.

Vesical Calculus with a Catheter for Nucleus.

A man suffering with stricture for many years had a No. 1 catheter introduced, and was allowed to walk home with it in situ. When he arrived the catheter was missing; it had slipped into the bladder. Six months subsequently symptoms of

stone developed, and upon operation the catheter was found as the nucleus of a calculus. Dr. Mel-don, who reports this case in the *Med. Press*, March 21, 1883, points the moral that we should never allow a catheter to remain in the urethra unless it is securely fastened.

Reposition of Inverted Uterus.

In the *British Medical Journal*, March 24, 1883, Dr. Arthur W. Edis relates a case of complete inversion of the uterus of five years' standing reduced within seventy-two hours by means of Aveling's uterine repositior. Each morning the instrument was removed, and the vagina syringed out with diluted Condy's fluid. Some adhesions between the fundus uteri and posterior vaginal wall were torn through with the finger.

Granulated Milk.

The *Med. Record*, April 7, 1883, says that granulated milk is made by subjecting milk to a temperature of 130° until the watery part has been evaporated. It is then granulated, and sugar is added, when it looks like corn meal. The evaporated milk is not as solid as condensed milk, and when water is added it cannot be distinguished from natural milk.

Drainage of Medullary Cavity.

In a case of chronic diffuse osteo-myelitis of the humerus, Bleckwenn resected the head, and drained the shaft, by trephining the lower diaphysis, and removing the medulla. Recovery, with a useful arm, resulted. The case is reported in *Centralb. f. d. Med. Wis.*, February 24, 1883.

Uræmic Coma Hastened by Morphia.

Dr. E. T. Hubbard, of Madison, N. H., sends to the *Med. Record*, March 10, 1883, the case of a man with Bright's disease, who had suffered with renal colic for fifteen years. He was given half a grain of morphia in the course of an hour, fell into a comatose condition, and died in three days.

Syphilis in the Monkey.

M. Martineau has inoculated a monkey with syphilis. On the fifteenth day mucous patches and constitutional disturbance were manifest. We await further developments.

Resorcin for Chancres.

In the *Ann. de Gyn.*, January, 1883, MM. Le-bland and Fissiaux give an account of six cases in which the chancre was brushed over with a solution varying from a weak to a saturated ethereal solution. Rapid healing took place.

CORRESPONDENCE.

Iodide of Potassium Poisoning.

EDS. MED. AND SURG. REPORTER:—

E. B. C., æt. 45, American machinist. Mr. C. presented himself for the treatment of a growth situated on the back to the left of spinal column, and between it and the left scapula. Not being satisfied as to the nature of the growth, I ordered application of an ointment of potassium iodide ($\frac{\text{gr. } 3}{\text{℥ i}}$ of vaseline) and internally a mixture of the drug, each dose containing about 10 grs.

After taking the first dose in the evening of February 25, 1883, patient exhibited coryza, laryngitis, conjunctivitis, and much œdema of eyelids. Naturally, he supposed he had contracted a severe "cold." The following morning, after having taken another dose, the symptoms rapidly increased in severity until the eyes were nearly swollen shut; the sense of smell being abolished, and dyspnoea so great that respiration was with difficulty continued. I gave him tinct. aconite in small and repeated doses, with diuretics; also ordered mustard to throat over larynx and trachea, and also strong mustard paste to the plantar surfaces of the feet. Then, after placing him in the kitchen, where the atmosphere was charged with steam, I left.

He rapidly improved, and in a couple of days the symptoms of inflammation had nearly disappeared. Then, thinking that I would try smaller doses of the iodide, I began with $\frac{1}{2}$ gr., when the symptoms again reappeared although not in such a severe form. I then withdrew the drug, when the symptoms disappeared.

I will not burden your readers with the progress of the growth, as this is written merely to recall to mind the idiosyncrasy of some patients respecting the iodide. I might state that Mr. C. had previously enjoyed excellent health, having boasted that he had scarcely ever seen a sick day excepting in the subject of "colds."

HORACE R. POWELL, M. D.

Poughkeepsie, N. Y.

Opium Addiction.

EDS. MED. AND SURG. REPORTER:—

In your journal of February 3 is a brief letter from Dr. W. S. Martin, on "The Opium Habit," citing the case of a young man addicted to morphia to the extent of 2 to 3 drs. per week, for more than two years, who, it was asserted, "stopped it at once, without any inconvenience, or the ill effects so usually experienced from its use. Had no effect on him perceivable. Says he feels as well as ever he did in his life, and has from the day he stopped."

During the decade in which we have been giving attention to opium addiction, we have met many habitues, but never such a remarkable young man as this; and feeling convinced that the fellow was lying, we wrote to Dr. M., expressing our *entire disbelief* in his patient's story, even though supported by a sworn statement, unless proven true by a chemical examination of the young man's urine, showing absence of morphia.

To this no reply was given.

Dr. Martin closed his letter by saying, "Any

light that I can procure on this subject would be gratefully received by me."

Well, the "light" has reached him, and he is a wiser man, for here is the sequel of the Munchausen tale.

A medical gentleman, several years addicted to morphia, who had recovered under our care, wrote to Dr. M., expressing an opinion similar to ours, and received in answer: "Undoubtedly you are correct. I was never more deceived in humanity than I was in this case. I could have taken the young man's word as far as most men's oaths; but he deceived me, for I have taken the pains to learn since that he is procuring the drug from another source."

So endeth the first chapter.

J. B. MATTISON, M. D.

Brooklyn, N. Y., March 31, 1883.

NEWS AND MISCELLANY.

The New Code.

To the Members of the Regular Medical Profession in the State of New York.

GENTLEMEN: Representing a large number of physicians associated to uphold the National Code of Medical Ethics, we beg leave to ask you to consider the importance of the object.

The so-called new code recently adopted by the Medical Society of the State of New York sanctions fellowship by means of consultations with all practitioners who are "legally authorized to practice medicine." This sanction extends to practitioners who have adopted designations intended to distinguish them as belonging to sects apart from, and hostile to the regular medical profession, and who are organized in order to lessen public respect for this profession and for its members. Will you not seriously consider the question whether under the circumstances affiliation by any act with sectarian or irregular practitioners is consistent with a due regard for the honor of the profession, or with a proper self-respect?

The new code has dis severed all connection by representation, of the Medical Society of the State of New York and its auxiliary county medical societies, with the American Medical Association, and also with the state medical societies of the several states of the Union. At the last meeting of the American Medical Association (1882), the Judicial Council decided as follows: "Having carefully examined the Code of Ethics adopted by the New York State Medical Society at its annual meeting in February, 1882 (as furnished by the secretary of said society), the Judicial Council find in the said code provisions essentially different from, and in conflict with, the Code of Ethics of this Association; and, therefore, in accordance with the ninth by-law of the American Medical Association, they unanimously decide that said New York State Medical Society is not entitled to representation by delegates in this Association." The following is the by-law referred to in the foregoing decision: "No state or local medical society, or other organized institution, shall be entitled to representation in this Association, that has not adopted the Code of Ethics, or

that has intentionally violated, or disregarded, any article or clause of the same."

We submit for your consideration that the substitution of the new code for that adopted by the American Medical Association has inflicted upon the medical profession of this State a great injury and disgrace.

It is believed that the recent action of the New York State Medical Society in relation to the code of ethics is not sustained by the sentiments and judgment of the great majority of the medical profession in the State. But, even granting that they who are opposed to this action are in the minority, it must be admitted that the number is very large. The effect of the action of the State Society, if persisted in, will be a division of the profession of the State into two parties. In view of the evils which cannot but follow such a division, and the many advantages of harmony, we appeal most earnestly to those who have been led to approve of the substitution of the new for the National, to reconsider the matter, and we solicit the active coöperation of all who are in favor of the National code, in concerted efforts, to effect, as speedily as possible, a reversal of the action of the Medical Society of the State of New York at the annual meetings in 1882 and 1883.

Communications from societies and individuals who are in sympathy with associations for upholding the National Code of Medical Ethics, and resisting any modifications of that code which do not emanate from the American Medical Association, may be addressed to JOHN H. HINTON, M. D., No. 41 West 32d street, New York city.

Body Snatchers.

Apropos of our recent excitement over grave robbery, the following will prove of interest. An "old correspondent" sends it to the *Med. Times and Gaz.*, March 24, 1883:

"The following are extracts from my books, Sir. The highest price I paid for a subject from October, 1825, to 1831-32, when the Anatomy Bill came into operation, was fourteen guineas.

"June 1, 1826.—Paid Holliss and Vaughan, for getting a subject from Beccles in Suffolk—a man that Sir Astley Cooper tied the iliac artery on twenty-one years ago. Coach for two there and back, £3 12s.; guards and coachmen, 6s.; expenses for two days, £1 14s. 6d.; carriage of subject and porter, 12s. 6d.; subject, £7 7s.; total, £13 12s. N. B.—A surgeon residing at or near there had watched the case for years, and immediately his death took place wrote to Sir Astley, who sent for or came to me to spare no expense, but at the same time to make an arrangement with the above men to obtain it at the least expense I possibly could. The surgeon gave them every facility to obtain it.

"One preparation in the Museum, the Treasurer's books.

"May 10, 1827.—Paid Mr. Blewett, for Mr. Cooper. Vaughan, Holliss, and Llewellyn (Nottingham), for Mr. Rogers. Mr. Rattenboro, £17 17s. 10½d. Paid Holliss, Vaughan, and Llewellyn, *finishing money*, £6 6s.

"January 29, 1828.—Paid Mr. Cock, to pay Mr. South, half the expenses for bailing Vaughan from Yarmouth, and going down, £14 7.

"1829.—May 6, paid Vaughan's wife 6s. Paid Vaughan for twenty-six weeks' confinement at 10s. per week, £13. June 18.—Paid Murphy, Wildes, and Naples, *finishing money*, by order of Mr. Cooper, £6 6s. November 9.—Two males and two females (Murphy), at £12 12s. each, £50 8s. November 25.—Page, etc., for one male and one female, £25 4s. Ditto, one opened female, abdomen only, £8 18s. 6d.; total, £34 2s. 6d. November 30.—Returned to Vestry Clerk of Newington, by order of the Treasurer, one male and two females, purchased of Page, etc., on the 25th, who had broken open the deadhouse to obtain them.

"N. B.—Sir Astley, great friend to Naples, wants young subjects from two to eight or ten. Coach Sunday morning service (perhaps to observe fresh interments in the burial ground)."

U. S. National Museum.—Lectures upon Materia Medica.

Dr. D. W. Prentiss has been invited to deliver a course of lectures in connection with the department of Materia Medica of the National Museum.

This course, which will consist of eight lectures, will be illustrated by specimens and other material from the collections of the Museum.

They will be delivered at 4 o'clock on successive Saturday afternoons, beginning Saturday, April 7.

These lectures are free. Persons desiring to attend must be provided with tickets, which may be obtained by application through the mail or in person to Mr. S. C. Brown, Registrar of the Museum, at his office in the northwest pavilion of the new building.

SPENCER F. BAIRD,
Secretary Smithsonian Institution,
Washington, D. C.

Astley Cooper Prize.

From the *Lancet*, March 10th, 1883, we learn that the next triennial prize of \$1500 will be awarded to the author of the best essay or treatise on "Diseases and Injuries of the Nerves and their Surgical Treatment, together with the operations performed upon nerve-trunks in the treatment of various diseases, and descriptions of the changes which ensue in other structures as well as in the nerves themselves from these operations." The condition annexed by the testator (the late Sir Astley P. Cooper, Bart.) is, "That the essays or treatises to be written for such prize shall contain original experiments and observations which shall not have been previously published, and that each essay or treatise shall (as far as the subject shall admit of) be illustrated by preparations and by drawings, which preparations and drawings shall be added to the museum of Guy's Hospital, and shall, together with the work itself, and the sole and inclusive interest therein and the copyright thereof, become henceforth the property of that institution, and shall

be relinquished and transferred as such by the successful candidate." The essays must be written in the English language, or, if in a foreign language, accompanied by an English translation, and must be sent to Guy's Hospital on or before January 1st, 1886, addressed to the physicians and surgeons of Guy's Hospital.

A Chinese Physician in New York.

Dr. Chew King Fong, who has a large practice among Chinamen in New York, recently applied to the Board of Health for recognition. The *Med. Record* tells us that he can talk no English, but showed a certificate issued by the Harbor Department, Hong Kong, and affirming his qualifications as surgeon of a Chinese emigrant ship. The certificate was not recognized, and Dr. Fong will have to be examined, and the *Record* sarcastically adds: Assuming that he passes, the serious question arises whether it would be proper to consult with a person who practices, it is said, on strictly Oriental principles.

A Sharp Retort.

Dr. John Woodward, a famous English physician of the early part of the last century, quarrelled with the celebrated Dr. Mead, and, meeting him accidentally under the gate of Gresham College, they drew their swords. Woodward's foot slipped, and he fell. "Take your life," said Mead. "Anything but your physic," replied Woodward, with his usual sarcasm.

How to Win Success.

Sir James Y. Simpson says: Do not vainly flatter yourself, as is too often done by the younger members of our profession, that in the chances of our calling fortune may, while you repose in drowsy sloth and idleness, search you out in order to lay her gifts at your feet. To obtain these gifts, you must arise and actively pursue her.

The College for Medical Practitioners of St. Louis.

The College for Medical Practitioners of St. Louis opens its third and last session for 1882-83 on May 7.

Items.

—The Library of the Royal Medical and Chirurgical Society of London contains 33,500 volumes.

—The people of this country consumed 95,000,000 gallons of beer last year, at a cost of \$250,000,000.

—In Vienna they're first rate at diagnosis; but then, you see, they always make a point of confirming it by a post-mortem.

—The *Wiener Medicinische Blätter* has been confiscated by the Austrian authorities on account of an article which appeared in it criticising the sanitary arrangements of the army.

—A surgeon once jeeringly asked a Quaker if he could tell the difference between "also" and "likewise." "Oh, yes," said the Quaker; "Sir William Fergusson was a great surgeon—his skill as an operator was admitted by almost every one. You are a surgeon *also*, but not *likewise*."

—The government of Brazil has awarded a gratuity of about \$17,000 to Dr. John Baptist Lacerda for his discovery of the antidotal virtues of permanganate of potash in the poisoning of snake bites.

—The venerable Sir Moses Montefiore will, on October 25 next, enter upon his hundredth year. According to "Webster's Red Book," there are at least twenty baronets living who were born before the commencement of the present century.

—Professor Nordenskjöld, during his Arctic voyage, was perplexed by the question, What becomes of the bodies of animals which die a natural death? He very seldom found such remains, and declared that on Spitzbergen it was easier to find vertebrae of monster extinct reptiles than the bones of the seal, walrus, or bird of the present day. The problem is yet unsolved.

OBITUARY NOTICES.

DR. E. B. TWINISPEED.

Dr. Edward Beman Twinispeed, a distinguished surgeon of Columbia, S. C. died April 19, aged 52.

He studied in Paris, and was a surgeon in the Russian army during the Crimean war. He was knighted and decorated by the Czar, and was the inventor of many surgical instruments now in use. He was a contributor to medical journals in America and Europe.

MARRIAGES.

CHRISTINE—HARRISON.—In the Park Avenue M. E. Church, April 12, by Rev. E. Griffiths, pastor of the church, assisted by Rev. W. Williams Christine, of the New Jersey Conference, G. Maxwell Christine, M. D., son of Prof. F. F. Christine, of the Central High School, and Miss Amanda E. Harrison, all of this city.

KEATING—WEDIN.—On Monday, April 2, by Rev. D. Seney, at St. Mary's Church, Jersey City, John Keating, M. D., and Mary Louise, daughter of N. P. Wedin, of Jersey City.

PEABODY—HUGGINS.—At Calvary Church, New York, on the 18th of April, by Rev. Henry Y. Satterlee, D. D., Dr. George L. Peabody and Jane de P. Huggins, daughter of the late James S. Huggins, Esq.

RANKIN—GRACEY.—On April 11, 1883, at the residence of the bride's father, Robert Gracey, Esq., Allegheny, Pa., Dr. Wm. D. Rankin and Miss M. Emma Gracey.

SAGEMAN—PITTS.—At Brooklyn, N. Y., Wednesday, April 4, by Rev. J. C. Agar, Dr. Lewis W. Sageman, of Mount Vernon, and Miss Laura L. daughter of Friend Pitts.

WRIGLEY—MACLEOD.—In Trinity Episcopal Church, Williamsport, Pa., March 29, by Rev. George C. Foley, J. Kay Wrigley, M. D., of Ansonville, Pa., and Susan Fenwick MacLeod, of Williamsport.

DEATHS.

BEACH.—At Dover, N. J., April 20, Dr. Columbus Beach, in the 68th year of his age.

MARVIN.—In Brooklyn, N. Y., on Saturday morning, April 14, George Howard Marvin, M. D., son of Charles R. and Mary E. Marvin, in the 44th year of his age.

MOORE.—At his residence, in New York, April 18, Charles H. Moore, M. D., in his 33d year.

PEARSON.—In Philadelphia, April 12, Dr. Charles L. Pearson, of Trenton, N. J.

RIGGS.—At Saranac Lake, New York, on Wednesday, April 18, 1883, Benjamin C. Riggs, M. D., in the 39th year of his age.

ROSENCRANTZ.—In this city, on Sunday, April 22, Dr. John Rosencrantz, in the 74th year of his age.

LECTURE.

ON THE TREATMENT OF TYPHOID FEVER.*

BY PROFESSOR GERMAIN SEÉ,

Paris, France.

GENTLEMEN: It is now too late to speak of the efficient causes of the epidemic, now happily on the decline. It is to be hoped that before another epidemic shall rage in our midst agreement will be attained on etiological points now under dispute; whether, for instance, typhoid fever invariably or generally owes its origin to putrid infection by ordinary faecal matters, or to blood poisoning by the specific evacuations of typhoid patients, or (as others will have it) to some unknown influence from the soil, or to some pernicious alteration in the water or milk that people drink, or to atmospheric infection by bad drainage, or overcrowding; or whether, lastly, the typhoid poison be schyzomycetes, or the typhoid bacillus of Klebs.

If, however, certainty cannot yet be attained as to causes, the question of treatment none the less demands our serious attention; for the wards of our hospitals are seldom free from typhoid patients, and sporadic cases are constantly occurring in our private practice. We must approach this subject, then, with such light as we have.

Curative Methods.

There exist three grand curative methods: the first has been from all time called expectancy, and is to-day dignified by the qualification, *armed expectancy*. The second, called the "specific

method," aims to destroy the contagious germ, the supposed cause of the disease. The third, less pretentious, but in the present state of our knowledge the most rational, comprises various means for counteracting excessive heat production (antithermic remedies) and for the abstraction of pyrexial heat [divers antipyretics, of which the local application of cold is the type].

1. Expectancy.

This method makes much account of hygiene and the *vis medicatrix naturæ*, to which mainly the case of the patient is left. Nature is to be watched severely, rigorously, and whipped into line at the least deviation from the normal march of the disease. Every exaggerated symptom is to be repressed. Has the patient diarrhoea of colliquative form? Opium must be given. Is there constipation? A little Hunyadi Janos. A congestion or catarrh from pulmonary blood-stasis and general weakness? Leeches, cups, or a large fly-blister. Are there ataxic manifestations? Musk, camphor, etc., are ordered.

[Prof. Seé gives a qualified acceptance of the expectant method in mild cases of the regular order which need little medicine, and only the supporting régime. He adds that the rationality of this system of treatment, when applied to all epidemics, is not obvious. What are we to understand by "deviation from the regular type?" It is notorious that certain sporadic cases and certain epidemics do not conform to the classic description; in some the disease is marked by excess of diarrhoea, or by constipation; in some thoracic symptoms are predominant; in some the fever is pseudo-intermittent from the outset. In these cases the excess of diarrhoea, the bronchitis,

* An abstract of a lecture delivered before the Academy of Medicine, and translated from the Bulletin de l'Académie by E. P. Hurd, M. D., Newburyport, Mass.

ete., is the rule. The advocate of expectancy, however, has his model in his mind, and every patient is put upon the *laissez faire* or symptom-treating régime; a little dog-grass tea, with nitre, a little vinous lemonade, with broth or porridge, a cataplasm and an enema, complete the prescription. Prof Seé thinks that when expectancy calls itself "armed," it ceases to be expectancy.]

The Antiseptic Method.

The antiseptic method has for its object to destroy the germinal principle of the disease after absorption, and even after the entire organism has been invaded by it. Whether the *materiæ morbi* be a chemical ferment or a low organism (micrococcus, specific bacillus) antiseptics aims to neutralize or annihilate it. It must be premised that there is a wide difference between destroying a microbe of putrefaction in a flask, and in attacking the same microbe when it has pervaded the whole mass of the blood; and yet it is gravely held by the advocates of the antiseptic treatment of putrid and zymotic fevers, that the same chemical substances which destroy germs in liquids out of the body, have the power to pursue the disease parasite through the most distant ramifications of the vascular system, and into the minute recesses of the tissues. Here we have a list of specifics theoretically infallible, which, already long, receive additions every day. Let us glance at these germicides.

1. Chlorine: recommended fifty years ago by Bouillaud and Chomel, now seldom used internally.

2 Mercurials: recommended in 1847 by Lerres (inunctions and the black sulphuret). This medication still survives in the calomel treatment of Wunderlich, Liebermeister & Hallepeau.*

3. The sulphites and hyposulphites, which derive their ancient repute from the property which sulphurous acid possesses of arresting fermentations. This is Polli's famous treatment, combated vigorously in Polli's own country by Semmola, and now virtually abandoned.

4. Iodine, to which Binz has recently called attention, as a powerful antiseptic of the laboratory; Liebermeister and Vulpian have tried it without success.

5. *The Salicylic Group.*—In this class we have the following acids, all of them antagonists of fermentation and decomposition: (a) carbolic acid;

(b) thymol; (c) benzoic acid; (d) salicylic acid, which is the most potent, most inoffensive, and the most used; (e) resorcine; (f) kairine, the subject of recent experiments. All these have a similar chemical composition and analogous effects, being bactericides in suitable quantities.

Action of Antiseptics on Micro-Organisms.

Of the microphytes which give rise to decomposition, we may omit the torula of saccharine fermentation and the mould fungi, confining our attention to the schizomycetes or bacteria, whose infecting property is not contested. We remark that contagion operates by quantities that are infinitesimal. So minute the infectious matter, so rapidly does it multiply in the organism, that we cannot regard it as a chemical ferment, but as a product of life (*contagium vivum*).

Designated under the name of bacteria, the microphytes of which we are now to speak consist of simple cells, without chlorophyll (micrococci), or they have the appearance of roots or filaments (bacilli). Their fecundating power is such that in twenty minutes, at the temperature of the body, they may double in number; their vitality surpasses that of all other organisms. They multiply by bipartition, or by spores. The latter possess extraordinary vitality, preserving their properties unimpaired for years, while their filaments perish.

These bacteria live principally on albuminoids, and of the non-azotized substances that serve them as nutriment, they subsist best on the saccharine. Water is indispensable; the greater part depend on free oxygen, such as the bacillus of malignant pustule; others, however, subsist without free oxygen.

Their Place of Origin.—All are believed to come from the soil. Nœgeli and Pettenkofer, who maintain the theory of the influence of the soil on the development of microbes, consider that a great dryness of the soil is necessary, and intense atmospheric currents. This is the opposite of what is generally admitted; great epidemics are attributed especially to dampness of the soil. Soyka maintains, as a result of numerous experiments, that the schizomycetes, after undergoing development in ground moisture, obtain access to the air, especially when favored by violent winds. He affirms that he has witnessed this fact.

If this view be correct, we understand the mode of infection by water and by milk.

Concerning the micro-organisms of typhoid fever, three kinds are found with great regularity attendant on this disease:

1. Certain "micrococci," which have but a sec-

*[Note by the translator. It still survives and makes a bold front in this country, and in the practice of Dr. James C. Wilson and other eminent authorities has been highly successful. Vide *New York Medical Journal*, March 17, 1883, p. 297.]

ondary importance, being found in the blood and tissues of other diseases as well.

2. The bacillus of Klebs.

3. Eberth's bacilli.

The latter are short and thick; those of Klebs are long and thin, and found especially in the parts where the disease commenced, principally in the necrosed portions of the intestine.

According to Koch, the bacilli which are found in the necrosed parts are those of Klebs; but in general all bacilli found in the deeper layers of the mucous membrane are those of Eberth. These have the most probable etiological relation to typhoid fever.

Introduction into the Economy.—It is rare that they penetrate the system by the digestive organs; the acids of the stomach destroy them. Their germs doubtless exist in all liquids; it is then probable that we introduce them into our food and drink, but they are not absorbed, at least in a healthy state of the *primæ viæ*.

The lungs constitute the largest absorbent surface, yet at autopsies we rarely meet with microbes in the lungs. How do they get access to the blood? We know only by conjecture.

Diffusion of Micro-Organisms.—The thick, club-headed rods of Eberth are the sole bacilli of typhoid fever, according to Koch and Friedlander. The filaments of Klebs are seen only in the necrosed parts.

The "micrococci" are but a manifestation and accompaniment of putridity, while the bacilli are etiological.

First Appearance of the Rods (Bacilli).—In the first week the bacilli are found in abundance at the bottom of the intestinal glands, and even in the adjacent parts. They are not found in the deeper tissues. In the second week, and the beginning of the third, they are found in the glands of Lieberkuhn, and in the mucous membrane itself, undergoing development with the progress of the disease.

Lymphatic Glands.—Eberth found the lymphatic glands full of microbes from the eleventh to the fourteenth day. Microbes were found in the spleen after the fifteenth day. Klebs has found them in the brain, and in the arachnoidean space, in great abundance. They have not yet been found in the kidneys. Eppinger has found the specific bacilli in the larynx, and in ulcerations of this organ.

Resumé.—Beginning in the intestinal glands (rarely in the bronchioles and pulmonary alveoli), the bacilli remain awhile in the bottom of the glands, then advance to the deeper parts, pene-

trating to the muscles of the intestine, then to the serous envelope, and the lymphatic spaces. A little later they invade the mesenteric glands and the lymphatics of the abdomen. Later still they appear in other organs. After the fifteenth day, only the debris of the mucous membrane remains.

The question now reappears: Can antiseptic remedies, introduced into the economy, destroy these micro-organisms? Have they any effect on the spores, so tenacious of life, as before said? Can they, at least, prevent the development of bacteria?

Bucholz has sought to determine what is for each antiseptic the minimum dose necessary to arrest the development and proliferation of bacteria. In this connection, he cites, in the first place, corrosive sublimate, which acts in a solution of $\frac{1}{20000}$; of thymol and benzoate of soda, $\frac{1}{20000}$ suffices; of benzoic acid, $\frac{1}{10000}$; of salicylic acid, $\frac{1}{3000}$; of carbolic acid, $\frac{1}{200}$; of quinine, the same. Chloral, iodine, and salicylic acids, when employed to prevent the diffusion of parasitic microbes, act in more feeble dilution.

These data go to show that as far as the internal action of certain of these substances is concerned, it would be necessary to use large quantities of the medicament to rid the tissues or liquids of the organism of the morbid bacteria: these doses would certainly be toxic.

Phenic acid may be an excellent antiseptic for wounds, without having any power to act on micro-organisms which have penetrated the economy. The same may be said of many other germicides.

Gueneau de Mussy, Hérard, Hallepeau, prescribe one to two gram doses of salicylic acid. Lille orders carbolic acid. All this is a mistake, for one of two things must be intended: either to pursue the typhoid bacillus in the intestines, which is impossible with these remedies, for they are absorbed in the stomach, taken into the blood, and reappear in the intestines under the form of salicylate of soda, with feeble or no antiseptic properties; or else the medicament is intended to antagonize the putrefaction of the contents of the intestines. In the latter case it is not given as an *anti-bacillic* remedy, but to counteract putrefaction, and prevent resorption of intestinal matters. This brings us back to the old notion (well nigh obsolete at the present day) of intestinal septicæmia.

[Prof. Seé concludes this heading by condemning the antiseptic method as irrational, and if logically carried out, dangerous. The largest doses which it is possible to give with safety, of

salicylic acid, which is the only antiseptic to be seriously thought of in this connection, neither destroy the disease germs nor prevent their dissemination. He has known of a rheumatic patient, who while taking six to eight grains daily of salicylic acid, was nevertheless attacked by typhoid fever, which pursued its usual course, in spite of such efficient preventive treatment. He would not, however, entirely banish the salicylic group from the treatment of typhoid fever, for they are sometimes useful as antiseptics.]

(To be continued).

COMMUNICATIONS.

SCARLATINA: THE POSITION OF THE SYMPATHETIC NERVE IN ITS SYMPTOMATOLOGY AND BELLADONNA AS A MEANS OF THERAPEUSIS.

BY HENRY BRATES, JR., M. D.,
Of Philadelphia.

Read before the Northern Medical Association of Philadelphia, March 9th, 1883.

Attendance upon a number of instances of scarlatina during the recent epidemic, has afforded ample opportunity of studying phenomena that early attracted attention, and impressed me with the fact that the *materies morbi* principally affects the region, the healthful accomplishment of the functions of which depends upon the integrity of the nerve designated in the title. These phenomena exist uniformly but to a varying degree of intensity in every instance of the disease. In a paper, it is impossible to describe in detail the characteristics of type or the peculiarities of individual cases, and it remains alone to be remarked that in some there may be a conspicuous absence of one or more symptoms, but invariably the principal element, *altered nerve function*, is manifested in every case. The *materies morbi* is a definite and distinct poison that affects mankind in *one* manner only and through *one* system, and the intensity of its effects with the so-called types of scarlatina, are but varying manifestations of *one* operative cause, differing not so much by imaginary small and large doses of the toxic agent, as individual or constitutional powers of resistance to its influence. This assertion is based upon the indisputable fact that the most malignant types, by contagion, are frequently contracted from the mildest, and vice versa. The phenomena to which attention is especially directed comprise *rapid pulse*, rise of temperature, and coincidently therewith, changes in the character of the pulse, *epigastric pain*, vomiting, gastric irritability, *diar-*

rhea and its liquid character, cephalalgia, vertigo, delirium, convulsions, coma, angina, condition of tongue and the exanthem. It is not to these mere conditions that reference is made, but I desire to review their peculiar development and manifestation. Under *pulse* one fact occasionally met is, that during the first two or three hours of the stadium invasionis, it is occasionally retarded, *i. e.* when the temperature has already risen to 100° its rate remains normal. As a rule this does not obtain. Again, when the temperature indicates a bodily heat of 104° and 105° and the exanthem is manifesting itself, the pulse-rate is anywhere between 130 and 160, but when compared with the force of the cardiac action, it is *surprisingly compressible*. Vomiting and gastric irritability are differentiated because the former occurs spontaneously while the latter manifests itself by forcible emesis only when liquids or solids are ingested. The deeply seated epigastric pain is sometimes the very first manifestation of the disease, and when not complained of, can, with few exceptions, always be found by firm pressure. This symptom, when it is remembered how frequently desquamative nephritis proves a sequel of scarlatina—that diarrhoea of a liquid character is so common with the pain; that parenchymatous nephritis of a chronic type is coexistent with grave lesions of the renal ganglia; that these renal ganglia are a portion of the sympathetic nervous system—possesses a significance the importance of which will be appreciated as we advance.

It may be well to emphasize that, in scarlatina, the cortical region of the kidney is affected, and that the lesions of the renal ganglia co-exist in those instances of chronic renal disease characterized by cortical changes. Cephalalgia, vertigo, delirium, convulsions, and coma, are regarded as manifestations of the one cause, the special type of the symptom being determined by the individual peculiarities or varying powers of resistance. Angina constitutes one of the first evidences of perturbed function, still better demonstrated by the “strawberry tongue,” which usually develops twenty-four hours later. The exanthem is a direct result of *vaso-motor* disturbance, and needs no especial consideration at this time. The property *irritability*, so well known to result in paralysis, if its influence be intensified and prolonged, plays an important role in the symptomatology.

Before proceeding farther, in order that our memories may be refreshed by the picture of scarlatina painted by authors, quotations will be made from those most highly esteemed.

Anderson remarks that, of the *early* symptoms, *vomiting* is sometimes the only noticeable feature.

Aitken: It has been usual to give the name simple and benign to those cases where the fever maintained an inflammatory type, and where the perceptible *localizations* of the disease are expressed by the exanthema, severe catarrhal sore throat, and simple hyperæmia with catarrh of the kidneys. The primary fever may be sudden in its attack, or the patient may complain of weariness and depression for some days, or a feeling of sickness or slight indisposition during the period of incubation. The *early* symptoms, whatever be the variety, are *headache*, pains in *back* and loins, loss of appetite, sickness, and white tongue. Especial attention is directed to the fact that the pulse is *rapid in comparison with the degree of pyrexia* in the early stages.

Niemeyer: While few suffer from prodromal symptoms, the majority of victims are attacked *suddenly*. A sense of burning heat, *nausea* or actual *vomiting*, severe headache, feeling of great relaxation, pains in limbs, with a pulse of 120 or 130, characterize this type (simplex). Observe here that this rate of pulse obtains when the pyrexia has reached 104 or 105 degrees. *Pharyngitis* occurring *prior* or coincidently with the above, should lead us to suspect the great probability that even at this time we have to do with scarlatina.

Trousseau, referring to the general characteristics of the disease, says: As a general rule, I repeat, the period of invasion is *very* short in scarlatina. Continuing, he mentions the *frequent pulse*, and remarks, this is an important fact; for in studying the disease in its component parts, in speaking of scarlatina without eruption, we find that we often form our diagnosis solely from the *frequency of the pulse*, which is rarely met with in other affections liable to be confounded with scarlatina. Diarrhœa and vomiting accompany the pyrexia of invasion, and sore throat *always* shows itself *simultaneously* with the fever!

These serve to illustrate the general tenor of the descriptions by our highest authorities, and time will not further be consumed by multiplication of similar remarks. This brief review emphasizes the fact that *early* we have the phenomena of disturbed function dependent upon irritability of a depressing nature. Now observe the descriptions of the so-called anginose and malignant types, and notice the similarity of phenomena, only, as it were, having their nature magnified and rendered cognizable. Trousseau: There is a frequency of pulse *still greater* than in

simple cases; and sometimes in adults from the first day of the *fever*, even before there is any appearance of the eruption, the pulse is 130, 140, 150, or even 160. Disturbance of the *nervous system* at the same time supervenes in the form of great restlessness, convulsions, invincible insomnia, and delirium.

A case illustrative of scarlatina maligna is mentioned: A lady had been all day in frightful delirium; she had incessant vomiting, intense fever, a pulse too frequent to be counted, and extreme dryness of skin. The case terminated fatally that day.

In one of my own cases, a male child three years old was sitting at the tea-table eating, when he suddenly fell back in convulsions; vomiting occurred and high fever rapidly developed. He was seen within three hours of the accession of the disease. Coma already was pronounced; temperature 105.4; pulse somewhere above 190. Before morning the child perished. Two sisters were thoroughly convalescent from scarlatina anginosa.

Regarding the pyrexia, Trousseau and Stillé teach that it rises higher than in any other exanthematous fever. This well-known fact is emphasized!

Aitken narrates an account of scarlatina anginosa as follows: The symptoms of the anginose variety are more violent than in the preceding species; for *nausea* and *vomiting*, great *restlessness*, headache, and some *delirium*, frequently occur as early as the second day. The heat of skin is often more considerable, frequently reaching 105°, while the pulse is quick, feeble, fluttering, and indicative of the extreme debility the poison has occasioned.

Of the malignant types, sphacelation, etc., etc., still further disclose the nature of the effect of scarlatinal poison, and are demonstrations of an irritative principle that in increased activity results in paralysis of the nervous structure that governs nutrition of the area affected. That the poison is preëminently of a depressing and paralyzing nature is, by this time, apparent.

Regarding sequelæ, mention is made of only the ocular and aural. The sympathetic nerve, we know, presides over the functions of organic life, *i. e.*, *nutrition*. It is characterized by being composed of vesicular and gelatinous tissue, and arranged in a series of ganglia that extend from the subcranial fossæ to the termination of the cœcæx. Filaments supply the muscular coats of the arteries, and accompany these vessels into the interior of the cranium and supply their remotest ramifications. The *capillaries* are *entirely* under the

control of this system! Throughout its course along the cervical and thoracic spine, numerous intercommunications occur between it and the pneumogastric nerve. This fact is of interest in so far as the explanation of the occasionally seen slowing of the pulse, during the first few hours of the augmentation of temperature, is concerned. It is a well-known fact that drugs possessed of the power of increasing the heart's action by stimulation of the sympathetic or accelerator nerves, exert a similar effect upon the pneumogastric or inhibitory nerve, which action, for a time at least, is equal, the one to the other. Again, that this influence is due to an irritant, is demonstrated by the proneness to emesis and gastric irritability. The sympathetic or accelerator of the heart supplies this viscus with three pairs of trunks. The superior cardiac nerve originates at the superior cervical ganglion, which latter supplies the internal carotid artery with filaments and regulates the supply of blood, and consequently the nutrition of the area of distribution of this vessel.

In view of these facts, it requires no effort to comprehend the lesions, so common, that result in more or less destruction of the ear and hearing. Especially is this true when the continuity of structure is demonstrated by the direct intercommunication between the facial and auditory nerves, the intimate connection with the sympathetic by means of the members of the carotid plexus that unite the casserion ganglion of the trifacial, and through this, with the sphenopalatine ganglion, and again by the Vidian. The complete circle of nervous tissue is here seen, and the early manifestations of altered blood supply in pharynx, etc., are easily understood. While dwelling upon the superior cervical ganglion and its associations, it may be well to refer to the ulcerative keratitis and by no means infrequent blindness that occurs, and indicates that, through communicating filaments, the ophthalmic ganglion is a structure in continuity, and that this ganglion by its short ciliary branches includes the eye in the circle chiefly affected by scarlatina. These sequelæ further demonstrate the nature of the poison of this disease, and prominently assert its depressive influence and power to stop nutrition. The dura mater of the brain and its vessels are supplied by twigs of this same system, and one explanation of perverted intellection is thereby explained. The intimate association of the cervical ganglion with the nerves supplying the mucous membrane of the pharynx and that covering the palato-glossar and palato-pharyngeus muscles, its indirect union

with the chorda tympani and filaments supplying the lingual papillæ, satisfactorily explain why symptoms of angina are so easily seen in the earliest hours of the disease. In the throat the evidences of depressed function and vaso-motor paralysis are seen, and the nature of scarlatinal poison made plain, hours before the cutaneous phenomena present themselves. The middle and inferior cardiac branches connect with the recurrent laryngeal branches of the pneumogastric, and are principally of interest in an anatomico-physiological sense, and require no especial consideration here.

The great solar plexus and especially the renal ganglia and plexus with the trisplanchnic nerves, without occupying time in detailing their points of connection, it may be stated, satisfactorily explain why, when an irritative and depressing poison like that of scarlatina affects them, we have evidences, first, of epigastric pain, and if its influence continues and is intensified, the resulting interference with nutrition is followed by the paralytic or liquid diarrhœa. We now consider pyrexia, and call to mind that increase of temperature is dependent upon two principal factors: either heat production is normal and heat elimination diminished, or heat production is increased while its elimination is normal. This applies as a general rule. In some conditions elimination is increased but production is in excess of elimination, so that the total result is pyrexia. Time will not admit of detailing the scientific and profound researches of Prof. H. C. Wood in his studies in fever, and I can but refer you to his monograph for further investigation. It remains to state the facts he has proven.

First. External heat applied externally to the body of normal animals and man, so as to elevate the internal temperature, produces derangements of the functions of innervation, respiration, circulation, etc., etc., *precisely similar to those seen in natural fever*; the intensity of the disturbance being directly proportionate to the rise in temperature.

Second. Heat applied locally to nerve centres and to the heart, produces in the functions of these organs those disturbances which are *familiar phenomena of fever*; the intensity of disturbance being directly proportionate to the excess of heat.

Third. The withdrawal of excess of heat in acute fever is followed by a relief of the *nervous and circulatory* disturbances. It is to be remembered that we here have to do with constitutions in other respects normal, and that the results are dependent upon the *artificial, external* application

of the essential phenomenon of fever, or that condition known as pyrexial. If the order of cause and effect be reversed, and the physiological be compared with the pathological, we will state that a poison *primarily* affecting the centres controlling the phenomena of heat production and heat elimination, and producing in these centres the same changes, either of structure or of functional activity, that *follow secondarily to artificially applied heat*, will be followed by fever; *i. e.*, increased bodily temperature.

Wood inquires: What is the mechanism by which the production and dissipation of *animal heat* is regulated in the animal organism; and, is this rise of temperature in fever due to the excessive retention or to abnormal production of heat, or to both combined? By an elaborate and most carefully conducted series of experiments, he has shown that section of the spinal cord is followed by increased heat elimination, and that the degree of this depends upon the proximity of the section to the brain.

In these researches it was ascertained, however, that the total amount of heat eliminated was greater than that produced, and while the surface of the subject was warmer than the norm, the total or bodily temperature was really reduced. When section of the cord is made, there is practically an organic paralysis of the vaso-motor nerves and a consequent dilatation of the peripheral capillaries, with, of course, increased cutaneous hyperæmia. Under these circumstances it is certainly manifest that increased elimination of heat must occur.

In this fact lies the answer to the question, *viz*: the mechanism controlling heat elimination is the vaso-motor nerves or system. The parallelism of the phenomena attendant upon artificially induced vaso-motor paralysis and that due to the poison the manifestations of which are denominated scarlatina, is at once apparent! The variations of this one symptom in the latter from the former, it must be remembered, are due to the incomplete paralysis resulting from the *materies morbi* and the ability with which compensatory actions on the part of the economy can be exerted. Artificially, the paralysis is complete and irreparable; in scarlatina it is partial and susceptible of influences through compensation. It will immediately be remarked that in scarlatina we have a *total increase of bodily temperature*; while in the experiments there was, in reality, a diminution. This apparent discrepancy is explained by the following considerations: In physiological investigation a single point is disturbed and the rest

of the system is normal, while in scarlatina the vaso-motor system is not the only portion affected; and it is probable that a caloric centre may, by the same influence that *paralyzes* the vaso-motor centre, stimulate the heat nucleus.

The following will prove if this hypothesis is admissible and true. Division of the spinal cord above the origin of the splanchnic nerves is usually followed by an immediate very decided increase in the amount of heat dissipated from the body, and also by a decided lessening of the amount produced. Before explaining these results, we must recollect that chemico-vital processes play an important role in calorification, and that active circulation, muscular action, and the consequent increased functional activity, dependent, it is true, upon the integrity of the nerves governing them, of themselves produce caloric; and when these functions are, in a measure, abolished, there is a decided diminution of heat production. This condition, do not forget, obtains only in a healthy animal, whose vaso-motor system is artificially paralyzed, and that while in this physiological condition we have heat eliminated in excess of production, in scarlatina we have the *same* eliminative factors at work, but at the same time *production of caloric in excess of that dissipated*, and a consequent pyrexia.

This increase of heat production may be stated to be dependent upon stimulation of a caloric centre, which conclusion would naturally lead us to state that the poison of scarlatina producing vaso-motor paralysis and consequent increased heat elimination, at the same time resulting in heat increase, must possess the property of stimulating the caloric centre while it simultaneously paralyzes the former; *i. e.*, the vaso-motor centre and caloric centre are differently affected by one poison. The vaso-motor centre we know to be situated in the floor of the fourth ventricle, near the apex of the calamus scriptorius, and if an effect to all the tract below this point results in increased heat elimination without any increase of production, there must necessarily follow a diminution of bodily temperature. This, it must be emphasized, will obtain only when a *depressing or paralyzing* influence exerts itself on the path indicated. Physiological investigation proves the above to be an indisputable fact, and also demonstrates that "section of the medulla oblongata, at its line of junction with the pons varolii in the dog usually leads to an elevation of temperature if the medullary vaso-motor centres are not in any way compromised."

To be continued.

HOSPITAL REPORTS.

BELLEVUE HOSPITAL MEDICAL COLLEGE.

CLINIC OF PROF. LEWIS A. SAYRE.

Reported for the MEDICAL AND SURGICAL REPORTER, by
Edward Develin, M. D.

Case 1. Anchylosis of the Elbow-joint.

GENTLEMEN: I here bring before you this man, suffering from an ancient fracture at the elbow-joint, which occurred last March and has been allowed to consolidate in a most unfortunate position—the arm being flexed at an obtuse angle of about one hundred and fifty-five degrees with the palm of the hand posteriorly. Fracture of the elbow-joint forms one of the most serious fractures we have to deal with. It is liable to give more trouble than any other fracture, but if you are compelled to cure it with ankylosis, it is necessary to place the arm in such a position that it will be of use to the patient. We are in some cases satisfied if we can compromise in the fracture and effect a cure with ankylosis if you cannot cure it with motion; but if you effect a cure with ankylosis with the arm at right-angles with the forearm in the position of semi-pronation, so that the palm of the hand can be brought to the mouth of the patient, you secure a useful arm; if the arm is straight, the man can only use it to carry baskets or such articles; the arm should be flexed in such a manner that the forefinger should be capable of entering any external orifice of the body.

The question before us in relation to this man is whether this fracture is completely consolidated, or whether it is only fibrous ankylosis of the joint, and can be broken up. If there is any motion here at all, I shall attempt to break up the ankylosis; but if there is no motion whatever, I would advise exsection. I shall now make firm and strong pressure upon the arm, and endeavor to break up the adhesions. (Dr. Sayre now stepped behind the patient, and bringing the man's shoulder against his own chest, with his right hand grasped the forearm in its middle third, while with his left he grasped the upper third. An assistant now held the arm firmly while Dr. S. made strong pressure by drawing the forearm towards him. At the first attempt no movement could be detected; the attempt being again made showed no signs of movement, but at this point the patient complained of faintness, and a slight movement was then detected; the fainting condition of the patient causing the muscles to relax, and advantage being taken of this condition, still greater movement was made, until gradually the palm of the hand was brought over the mouth. The patient, having completely fainted, was then laid on a table, and both flexion and rotation of the forearm secured, all adhesions being completely broken up.)

Having now thoroughly broken up all adhesions, now comes an important point—to prevent difficulty following this operation—as I desire to cure this man with free movement of the arm; if I continue these movements of flexion and rotation, I might provoke serious difficulty, and induce inflammation and suppuration at the joint.

In order to prevent inflammation following, I

shall bandage the arm snugly, and shall place a compress over the middle and lower third of the brachial artery, so as to prevent the full supply of blood to the arm, and by this means lessen the liability to inflammation; the arm must now be kept perfectly quiet for five or six days, during which time cold water applications will be made to it. Now use compression with judgment, for if it be too severe, you will provoke ecchymosis and gangrene of the parts; let the compress be applied with just sufficient force to check in part the circulation of the limb, but not to stop it completely.

In applying the compress, you observe one of my assistants places his finger upon the radial pulse, while another puts the compress upon the brachial artery, and I now secure it with a bandage. Should the pulse of the radial artery stop, the compress is too severe, and must therefore be applied with less pressure; you must regulate your pressure by the pulse. We have now bandaged the arm at right angles, and I now support it with a sling.

The House Surgeon will keep this man in the ward perfectly quiet for a time; should the arm become swollen and the fingers cold and blue, the compress must be removed at once, and reapplied as I have instructed you. In about six days you can remove the compress and bandage, and make slight movement at the joint; if you omit this the joint will certainly become ankylosed; you can then omit the compress over the artery, again applying the roller bandage to the arm, and in a few days take it down again and make passive motion. Continue this treatment, and in a few months the arm will have perfect motion and may be as useful as it was before.

I here show you a small thermometer, which is called Seguin's surface thermometer, by which the slightest rise in the temperature of any part of the body will be registered when placed in contact with the skin. Had I been unable to move this man's arm perceptibly, I should have used this thermometer upon his elbow, and if I had found an increase of temperature on the following day, I should be sure that I had made some movement of the joint, although it was imperceptible at the time it was made, thereby showing that there was not bony ankylosis, and that movement could be secured. I should then have administered an anæsthetic and broken up the adhesions; but as the man became faint, I noticed his muscles began to relax, I therefore took advantage of this condition and redoubled my efforts to secure movement, and with what result you have already seen.

I will bring this man again before you, and we will then note the result secured by this treatment.

Note at the following clinic.—This man you will remember I presented to you at our previous clinic. He was then suffering from ankylosis of the elbow-joint, at which time I broke up the ankylosis. During this time the House Surgeon has re-dressed the arm as previously directed, and informs me that no constitutional disturbance followed the operation; you observe that I can now make moderate flexion and extension of the arm. Passive motion is now to be made every day, but the movements must

not be carried to such an extent as to excite inflammatory action at the joint.

This may be known by the pain lasting more than twenty-four hours. If the pains which are produced subside during the day, then you can continue the movements, increasing them every day; but if, on the contrary, the pain lasts over twenty-four hours, you must cease further movements until all pain has subsided, and then do not make your movements quite so freely.

It is now evident that if this treatment be followed out carefully, this man will have free motion at the elbow-joint.

Case 2. Ankylosis of the Elbow Joint Induced by Erysipelas.

This patient now brought before you has been suffering from a severe attack of erysipelas in the forearm, and is brought here to-day to be treated for ankylosis of the elbow-joint.

It is possible that the inflammation may have caused this ankylosis, the House Surgeon informing me that the elbow has never suffered from any traumatic injury. The joint then, very probably, has suffered from the general inflammation also, and the ankylosis is the result. There is no active disease at the present time in the joint, as I can press upon it firmly without causing pain. Here we have then a dry joint. Now, on taking the arm firmly and endeavoring to make gradual flexion, we find a slight movement has been secured, and knowing that slight movement, though it be limited but rapid in its action, will start the secretions of the joint, we will make such movements, at the same time gradually flexing the arm; you now observe that the adhesions are gradually being broken up. During the time in which this arm has been at rest, the synovial membrane has not secreted any fluid, and hence the joint becomes dry, and ankylosis has followed. You now observe that the ankylosis is completely broken up.

Gentlemen, this is a practical case, and in relation to which I will venture a few remarks concerning those men who are so-called *natural bone-setters*. A few professional men in Europe have recently honored them by mentioning their names. Now, the important point which I desire to impress upon you, is the necessity of moving the ankylosed bones at the proper time. In this case before you, the patient might, for lack of proper treatment, have gone on for some time with the joint in this ankylosed condition, until, falling into the hands of these so-called bone-setters, they having no reputation or professional standing to uphold, by main force break up the adhesions, which the professional man should have done and would have done, had he known at what time to act. The gradual development of both bony and fibrous ankylosis should then attract your earnest attention in this direction.

Case 3. Gun-shot Fracture of Humerus.

Male, aged twenty-five years. This young man in July last was accidentally shot through the left arm, the humerus being badly shattered.

The rifle ball (No. 45 cartridge) entered at about the middle of the arm. It was then thought that the only chance for his life was amputation; he, however, refused to submit, and rode sixty-six miles on horseback through the mountains of

Montana in search of surgical aid, and consulted five medical gentlemen, who all agreed that amputation was necessary; he, however, would not submit to an amputation, and it was then decided to remove the fragments of bone, and saw off the jagged portion of the upper and lower fragments of the humerus. This was accordingly done, the patient being under ether and the operation conducted under the spray. The bones removed, when united, measured two and seven-eighths inches.

A most remarkable union has been the result of this operation; it is, however, simply ligamentous union, as you observe that the back of the hand can be readily twisted to the front, he being unable to raise the forearm; but you will here observe that upon the forearm being brought up to a right angle, he has a wonderfully powerful grasp of the hand. It is, however, not as powerful as the right hand, but is undoubtedly much better than an artificial arm. He states that he was confined to his bed for twenty-five days, and then for two weeks the arm was kept in a sling, after which time it was allowed to hang straight. By this means the weight of the arm has made too much extension, and the result is, as you see, the fragments have been separated, and in this manner prevented the possibility of bony union taking place. In many cases of ordinary fracture of the arm, we have non-union of the fragments from this same reason. I desire you to note my objection to Buck's continued extension in this matter. Continued extension I do not deem the proper treatment for fracture; what you need in a fracture is to make your extension and counter-extension until you have reached the point of accurate adjustment of the fractured bones, then use your means of *retention* or *fixation*, to prevent any possibility of the fragments overlapping. All the extension that is needed is to bring the parts into exact apposition; the muscles and vessels are then brought to their normal position also. Now by retaining them in that position there is no tendency to spasm of the parts, but if you continue the extension by means of the weight and pulley, there is a reflex spasm, a struggle on the part of the muscles to regain their natural position. This goes on day by day until the muscles are overcome and the bones become separated, and non-union is the result. I do not remember the exact per cent. of cases of non-union in fracture of the femur as given me by Mr. Hudson, but I attribute such non-union as the result of the treatment by this continued extension.

If you make your extension to a certain point and there retain the limb, I know of no reason why you should not effect a cure without shortening of the limb, but I do know that in some cases of fracture of the femur I have seen the patient recover with the same length of limb as previous to the injury.

It is certainly much better to treat the case with the hope of securing the natural length of the limb, than to make up your mind at the commencement of the treatment that shortening must inevitably occur.

This probably has been the case in this instance. It is now somewhat late to form any great anticipations in this case; I however intend to apply

the plaster bandage, and by this means form a support for the elbow, and also secure a cap for the shoulder. In this manner we shall bring the fragments closer together, and thus attempt to secure bony union in the place of the ligamentous union now existing. I do not, however, endeavor to bring the upper and lower fragments together in this case, owing to the ligamentous union which has already taken place. We will, however, form a shell for the arm, retaining the forearm at a right angle, as in this position it is of the most use to the patient. I notice that the elbow-joint is perfectly sound, and you can all observe the point at which the bone was sawn across by its projection above the elbow; the section being made about half an inch above the condyles, the olecranon is retained in its natural position.

We will now apply the plaster bandage, previously enveloping the arm in a piece of flannel; we pass the bandage from the wrist upwards, it is not, however, applied tightly, but forms a complete shell. The roller is now passed from the elbow over the left shoulder, bringing it under the axilla of the right side, then passing across the chest to the left shoulder down to the bend of the elbow posteriorly, and we thus form a sling for the arm; these turns of the roller being repeated as often as the case may require, the bandage then passing around the humerus and enveloping the whole. In this manner we secure a perfect support for the arm, and prevent any dragging upon the ligamentous union; and by keeping the arm quiet, earthy matter may perhaps be deposited in this cartilaginous material and ossification ensue. As soon as the plaster is set, we remove those bands passing across the chest and back, in order that the right arm may have perfect action.

In case no bony union takes place, we can sometimes excite fresh inflammation in the parts by passing an electric current through the ligamentous junction. In some cases it is necessary to make a fresh section of the bones and wire them together; in this case we will first try what rest and fixation will do.

I will endeavor to bring this patient again before you at a future clinic, and we will then note the results secured.

MEDICAL SOCIETIES.

PROCEEDINGS OF "THE COLLEGE OF PHYSICIANS OF PHILADELPHIA."

ewer Gas, and its Alleged Causation of Typhoid Fever.

BY GEORGE HAMILTON, M. D.

[Read March 7, 1883.]

(Continued from page 462.)

In this connection it must be stated that the reports of the Board of Health of Philadelphia show, unmistakably, that in the central portions of the city, where sewers and water-closets are most numerous, there is, as a rule, less typhoid fever and diphtheria than upon the outskirts, adjacent to

the country; and this was the fact in regard to bilious remittent fever, before it gave place to typhoid. Neither is it matter of surprise, for, just in proportion as the streets have been extended into the suburbs, graded and paved, houses erected thereon, and sewers constructed to carry off the surface drainage, a diminution of fever, whether intermittent, remittent, or typhoid, has been the beneficial result of such improvements. In support of this view we have the testimony of the late Dr. J. K. Mitchell, the distinguished and brilliant Professor of the Theory and Practice of Medicine in "Jefferson Medical College," as follows: In December, of the year 1850, he was called to consult with the late Dr. Gebhard and the writer in a fatal case of typhoid fever, in a house on 16th above Summer street—at that remote period an outskirt of the city. On his first visit the doctor informed us that he was scarcely ever called upon to visit a patient affected with typhoid fever in a large circle of practice in his own section of the city, but that nearly all such cases were, like the present one, in the suburbs, and in consultation. Now the important fact in this connection is, that in his own central position sewers, water-closets, and the usual well in the yard, were almost everywhere, whilst in the suburbs they were comparatively few in number, the water-closet exceptionally rare. Does it not seem singular then, that, despite the improved, the scientific, the sanitary plumbing of the present day, "nine houses out of ten, on Fifth Avenue, New York, are not safe to live in;" and that all the actual appliances for the exclusion of sewer gas should be torn out, and others of an effective character be constructed in a separate building or annex? Dr. Mitchell also made allusion to the greater prevalence and fatality of fever in the country, as related to him by students from different sections of the United States.

In the paper by the writer upon this subject before the College of Physicians of Philadelphia in 1879, Mr. Henry Dupont, in reply to a note, stated that his impression was that, in the years 1840-1-2-3, there were but few cases of typhoid fever among the thousands of operatives and their families on the Brandywine; and this impression was corroborated by a note from Dr. Jos. P. Chandler, a practitioner of that section, in which he said that whilst a very few cases seemed to owe their origin to local causes, his experience was perfectly in accord with that of the writer, that the disease nearly always showed itself in the houses of the farmers, and that no matter how well situated upon an eminence, with drainage in all directions from the residence, this did not secure them from attack. This is but a confirmation of the views long ago expressed by Dr. James Jackson, of Boston, and Dr. Nathan Smith, whose opportunities for observing the origin, development, and progress of the disease, were exceptionally abundant. In a note sent to me a few days after the reading of the paper just alluded to, the writer declared that nothing was more erroneous than the current of popular opinions in regard to the causes of typhoid fever, and, in proof of this, cited the condition of the streets of one or two of the most populous and commercial cities of Africa, abounding, as they did, with every conceivable

species of filth, emitting a stench nauseous to the last degree, and yet typhoid fever prevailed to a very slight extent. This statement is in accord with one quoted by Prof. Hamilton, in his paper, before alluded to, to this effect, that in Canton, filth beyond measure, typhoid fever and diphtheria are almost unknown.

In further support of these views, a physician of New England has informed the writer that a few years ago he addressed letters to about fifty practitioners, in different parts of the State in which he practiced, asking their experience in reference to outbreaks of typhoid. The answers, with very few exceptions, were, that the rural sections suffered the most, whether in regard to proportionate number of cases or fatality. Thus it now appears, as it did in the time of Nathan Smith and James Jackson, that typhoid fever outbreaks occurred without the possibility of referring them to the conjectural local agencies now in favor. Physicians who have not enjoyed sufficient opportunities to observe the origin and progress of typhoid fever, and sanitarians, without medical experience, are the most positive in opinion in regard to the primary causes of typhoid fever; whilst Trousseau, Flint, Sr., Murchison, and many others of similar experience and sagacity, freely admit the obscurity of this subject, and the difficulty of determining the influence of local agencies in the production of typhoid fever as compared with causes of a general character, over which we have no control, as in telluric or atmospheric conditions, involving thermometric, hygrometric, and electric states and their influence, singly or combined.

As pertinent to this point, reference may here be made to an article in the *MEDICAL AND SURGICAL REPORTER* for January 1, 1881, entitled "The Limited Effects of Sanitation," from the pen of Dr. John Syer Bristowe, President of the Society of Medical Officers of Health, as follows: "If we look to the remarkable influence which simple variations of temperature and peculiarities of season exert on the mortuary returns, in respect both of the number of deaths and the character of the fatal diseases, and compare therewith the comparatively small effect on the death-rate of even one of the most fatal of the zymotic diseases, or with the insignificant influence of deaths from enteric fever, diphtheria, pyæmia, puerperal fever, and other affections over which sanitary science is supposed to exert a specially valuable influence, we can scarcely avoid, I think, seeing that, on similar grounds, the deaths saved directly by the sanitary labors on which we are engaged must, under any circumstances, be so few annually as to produce no distinct and unmistakable effect on the mortuary rates." This sincere and ingenuous avowal of opinion by one so distinguished as an authority in medical science is well entitled to the serious consideration of the enthusiasts who never tire in predicting the suppression of the diseases in question so soon as sewer-gas and filth are banished from the houses and premises of our citizens; whilst it is a notorious fact that lavish expenditures of money, by public authority and by citizens, have for several years past been made in Philadelphia without any perceptibly important result as the consequence. In the paper of Prof. Hamilton it is distinctly

stated that, during a certain period, the increased mortality in New York could not be found in the condition of the streets, for at that time they were unusually clean; nor can the unusually severe outbreak of diphtheria now prevailing in our own city be attributed to the current local agencies. If, indeed, the primary causes of typhoid fever, diphtheria, and scarlet fever in cities be due to the influence of sewer-gas and filth, then, in fact, our citizens can have little hope of an early exemption from these maladies. Yet, on this score, there is no occasion to despond. Fifty years ago typhoid fever was not common, but intermittent and bilious-remittent prevailed in the city, yet only to a moderate degree compared to the suburbs and the adjacent country. These are not regarded as special filth diseases, whilst typhoid fever, diphtheria, and scarlet fever are by many so considered. At the remote period alluded to some attention was given to cleansing the streets, but there were no such exertions and expenditure of money, even in proportion to the size and population of the city, as are now customary; and as to inspection of dwellings, out-houses, wells, and the premises, it was almost unknown. That constant attention, by the authorities and citizens, should be given to maintain cleanliness in every place, and by all possible means, no one will deny; but, when all this has been done, what comparison can there be between the condition of a large city and any well-managed rural section in this point of view? Under the most favorable circumstances the sources of filth contamination in a city are as ten to one compared with the country; and this is manifest in the single fact, that the ground on which a city rests is, of necessity, well nigh riddled with wells for the convenience of families.

During the past ten or twelve years, the average weekly deaths from typhoid fever in this city have been from seven to eight, as above stated. If this disease had prevailed here, in frequency of attacks and fatality, in proportion to population, as the writer has known it to do in the country, forty to fifty deaths per week would have probably occurred. The same feeling of gratification that the late Dr. Jos. Parrish manifested and expressed when informing his class of the slight mortality from bilious fever in this city, as compared with the country, has been experienced by the writer in regard to typhoid fever in this city, as compared with what is seen from time to time in the country. The city of Philadelphia, as shown by the reports of the Board of Health, still maintains its title as one of the healthiest of the large cities of the world, nor is it good policy, under any circumstances, to do or say aught to inspire citizens with dread, and induce strangers, who may have occasion to visit us on business or otherwise, to regard Philadelphia as unhealthy, and therefore to be avoided.

[After the reading of the preceding paper:]

Col. Waring, who was present by invitation, was called upon by the chair to discuss the subject considered in the paper. He remarked that he desired to say one word for sanitary engineers with regard to the cause of typhoid fever, and this was that they had long since abandoned the opinion that sewer-gas was the cause of the disease. He thought it very important that filth

should be gotten out of the way, so as not to become a source of contamination to the water-supply. The literature of the subject seems to prove that typhoid fever in the country is due to drinking-water which has become contaminated. Cleanliness is safe and important, and efforts should be always made to secure it.

Dr. Hamilton said the quality of the drinking water remained essentially the same from year to year, whether typhoid fever prevailed extensively or was absent; so, also, in regard to vegetables and roots for family use. These are laid up every season, generally in trenches, covered with clean straw, and earthed over. On consulting several German monographs, Dr. H. had found the experience of the writers to conform with his own, that males suffered more from typhoid fever than females, and that from the fifteenth to the twenty-first year, the period of rapid growth, the danger, in case of an attack, was augmented.

Dr. J. M. Keating said that the elaborate paper we have just heard read might mislead some of its hearers into the supposition that *sewer gas* was considered a cause of typhoid fever. It may be well for us at once to dispel such an idea, and to couple with the paper just heard the emphatic endorsement of this body that *sewer gas*, as far as *typhoid fever* is concerned, is simply a *VEHICLE* by which the specific germ may enter the system of one prepared to nourish and develop it. There is no need to debate the question as to the greater importance of infected drinking-water; the incidents in the paper just heard, the greater prevalence of the disease in the rural districts where privy wells contaminate the drinking water, and the remarkable statistics of the New England country towns where the wells for sewerage and drinking purposes are under one roof, the fact that these localized epidemics are usually traceable to one primary case entering the village, are all sufficient evidence in themselves.

But though *sewer-gas* may not always carry the germs of typhoid fever, it has a poison of its own equally terrible in its consequences.

The modern improvements in house-drainage—indescribable comforts where properly constructed—are unfortunately too often the means of carrying the most deadly vapors directly into the abodes of luxury and wealth. At those hours when depressing influences have disarmed their victim, these noxious gases steal insidiously into his chamber, and do such violence as to render fatal by the most serious complications such diseases as are otherwise mild and harmless in themselves. Whether the concentrated miasm from pallidial emanations or the outpouring gases from a sewer through siphoned traps, the unconscious sleeper breathes poisons as potent in their devitalizing effects as if he inhaled the germs of typhoid fever in their purity, or drank water impregnated with the excreta of typhoid cases. *Sewer-gas* is not necessarily a *cause* of typhoid fever, except when it carries its germ, but it is the most potent cause of the "typhoid state;" and there is a decided choice between these two evils—in favor of the former.

Early manhood carries with it a decided predisposition to typhoid fever. I have recently read with great interest an article in the *Nineteenth Century*, by Gen. Sir Frederick Roberts, on the re-

cruits for foreign service in the English army, in which statistics were given to show that the large mortality from typhoid fever, in young recruits, rendered advisable the consideration as to whether it was not better for foreign service to take only such as had recruited early and survived this period, or to recruit only from those who had passed the age when the disease was most liable.

The typhoid germ is certainly more deadly if its vehicle be poisonous also; and it becomes our duty to add an earnest appeal to that which seeks by proper legislation to give us pure air for our children to breathe, and pure, uncontaminated water to drink.

Dr. J. G. Richardson remarked: I am well aware that the evening is too far advanced for me to attempt to discuss the important subject of Dr. Hamilton's paper, and I will therefore content myself with suggesting how two of Dr. H.'s illustrative cases may be very plausibly explained in accordance with the modern views respecting the danger to human health from impure drinking-water, foul sewer-air, and other grave sanitary errors.

Dr. Hamilton mentioned the case of the mother of a family who contracted typhoid fever away from home, and brought it back to her farmhouse, where several members of the family seemed to take the disease from her; and argued that this circumstance proved that the infection of typhoid fever was not carried by sewer-gas, because in this instance no sewers existed near the place. The true explanation of this seeming anomaly is, I believe, however, that whilst typhoid fever is sometimes carried by sewer-gas, it is more frequently conveyed in drinking-water contaminated by sewage, and that in this case the diarrheal discharges of the mother were emptied near enough to the family well to soak through the ground into it, and, by polluting the drinking fluid, transmit the disease to other members of the household.

That some such mode of propagation may have existed is shown by a remarkable fact related by Prof. Flint, upon whom Dr. Hamilton relies as an authority against the dangers from sewer-gas, which are briefly as follows: A young man traveling by stage-coach in Vermont was taken sick, and left at a wayside inn in a small village. His complaint soon proved to be typhoid fever, and in a short time the disease appeared in each of the neighboring houses, the inhabitants of which used water from the tavern-keeper's well, *except one*, whose residents had quarrelled with the landlord, and consequently went elsewhere for their water-supply.

In the light of recent sanitary science, then, it appears that many people, many whole families, in rural districts, suffer from typhoid fever because they drink well water, polluted by direct mixture with fecal matter containing the specific fever germ, which soaks through the soil, often directly, into the well; whilst in cities a few persons, relatively, are attacked with typhoid fever, and many with diphtheria, etc., by inhaling poisoned sewer-air from stationary wash-stands and other modern conveniences. There are probably one hundred thousand villages and farm-houses in the United States to-day, where the cess-pools

feed the wells in this abominable manner, and such wells surely in their turn feed from time to time the church-yards in their neighborhood.

Again, Dr. Hamilton inquires, why is it, if sewer-gas is the cause of both typhoid fever and diphtheria, we now have, according to late reports of the Board of Health, only two or three deaths per week from the former disease, and thirty or forty from the latter? The obvious answer is that sewer-gas can only convey the *materies morbi* (the disease germ as I believe it is) with which it is freighted, and at the present time sewer-air in but few houses is contaminated with typhoid-fever poison, whilst in many it is loaded with diphtheria germs—precisely as drinking-water might contain both lead and copper in varying proportions, and accordingly as one or the other temporarily predominated, would persons who imbibed the fluid be liable to exhibit the symptoms of lead palsy or of copper poisoning.

Although I am not yet prepared to endorse the dictum of a late English hygienist, who declares "For every death from typhoid fever, somebody" (meaning some plumber, architect, or sanitary engineer) "ought to be hung," I do hope and believe that the time is not far distant when at least the charge of criminal negligence will lie at the door of every physician who, after being warned by the occurrence of one case of typhoid fever, diphtheria, etc., in a dwelling, does not immediately endeavor to guard the other residents of that house against the germs (or poison, if you choose) of infectious disease, by a diligent search for the sanitary defects in the water or milk supply, or in

the disposal of sewage, which will almost certainly be discovered.

I have spoken of the germs of typhoid, diphtheria, etc., entering sleeping apartments from stationary wash stands in spite of traps, and in this connection I desire to show the Fellows of the College just how, as I conceive, these poisons may penetrate through such mechanical contrivances. Here I exhibit the ball of an ordinary Bower trap, covered with a coat of fungous growth, and here a portion of the slimy coating from one of the pipes of similar structure. Since these form a continuous lining quite through the trap, it is obvious, I think, that it may have crept up from the sewer itself, thus forming on the inner or house side of the trap a new starting point for the evolution of disease germs, against which, of course, the most perfect water-seal is absolutely no protection. This, I believe, is what really occurs in a multitude of instances, as I pointed out in a paper entitled "Why Sewer Traps are Unreliable" in the *Medical News* for September 2, 1882. The true remedy for the dangers of sewer-gas poisoning is, therefore, I think, as explained in that article, to be found in sterilizing the whole interior of our traps and waste-pipes with slow currents or drippings of powerful disinfectants, such as the salts of iron, zinc, mercury, or arsenic, "just as the shores of the Dead Sea and the banks of certain small streams are sterilized, by mineral ingredients or poisonous metallic substances, from manufacturing refuse, with which their waters are mingled."

EDITORIAL DEPARTMENT.

PERISCOPE.

Pulmonary Syphilis.

The *Med. Press*, March 7, 1883, thus writes: There are few diseases whose pernicious influences on the system are so universal and so diversified as syphilis. Its poison seems peculiarly inimical to fibrous structure, and consequently to the minute blood-vessels, and to the organs in which they ramify to the greatest extent. Certain recent works on this important subject have revived the interest in it which all physicians must feel; for example, the compendious memoir of Pancritius, the carefully-studied thesis of Carlier, and a series of communications made during the past five years to the Société Anatomique of Paris. These works examine exclusively the question of pulmonary syphilis in the adult. Pulmonary syphilis in the new-born is a subject totally *sui generis*, whose features have been grasped scientifically since the time of Cruveilhier, by such authorities as Baron, Billard, Husson, Virchow, Cornil and Ranvier, etc. All these authorities have reasonably concluded that the phenomena of infantile pulmonary syphilis are so characteristic that it is

impossible to confound them with those of any other affection. But if on this subject, from the point of view of pathological anatomy, so much precision has been attained to, it is quite otherwise with the specific pulmonary affection of the adult. Not a few physicians have hesitated to acknowledge their existence, while some have even totally denied them. Paré, Baglivi, and Astruc conceded that syphilis might originate destructive alterations of lung tissue, to which phthisis would form the rôle of a *secondary diathesis*, an influence, they also maintained, common to blenorragia. In short, the specific nature of pulmonary syphilis has been but very tardily accepted by the profession. Morgagni was an avowed partisan of the pulmonary syphilitic doctrine, but sufficiently authentic proofs thereof failed him.

At the commencement of the present century, Lammonier affirmed the existence of a phthisis of a syphilitic nature, and curable by the ordinary anti-syphilitic treatment. During the period of thirty years, commencing with Lennec in 1804, and which may be regarded as the Renaissance of pathological anatomy, syphilis was almost forgotten in this connection. Perhaps this was in great measure due to the influence of John Hun-

ter, who scarcely believed in any visceral complications of syphilis. It was not until 1826 that Lænnec and Andral described and recognized syphilitic phthisis. Van der Kolk maintained that syphilitic subjects sometimes died presenting "phthisical appearances, with ulceration of the lungs, situated most frequently in the middle lobe, *but without tubercle*." To Ricord is mainly due the recognition of syphilitic phthisis as one of the most certain and incontestable sequences of venereal infection; and Gilbert, Fournier, and especially Lancereaux, have substantiated by pathological anatomy, not only the possibility, but even the frequency of syphilis of the lung. The microscope has afforded in this investigation less assistance than one would, at first thought, be led to anticipate. The structural changes of syphilitic lung appeared only as common inflammatory changes, and no light was thrown on the original specific nature of the process. Hence, consideration of the larger lesions, and the history of the special case, furnished the only reliable elements of diagnosis. In the lungs, as elsewhere, the histological changes initiated by the syphilitic virus consist of nodes and sclerosis. Most frequently the sclerosis are superficial; they are pleuro-pulmonary, and appear as elongated depressions, more or less deep, and more or less bound down with bands. These depressions are, however, seen in the most characteristic form in the liver and spleen. From the surface of the lung, these fibrous bands penetrate the parenchyma of the organ, and radiate towards the hilus, as the septa of the testicle towards the body of Highmore. The *gummata*, on the contrary, are almost invariably situated in the deeper structure of the lung, and especially around the greater bronchi. Not frequently numerous, they have a firm consistence, are of a yellowish color, and of a peculiar dryness, which distinguishes them from the great bulk of other morbid products. Their size is variable, but they seldom exceed that of a hen's egg. As a rule, they co-exist with sclerosed induration of the parenchyma, and are encysted in fibrous rings or spheres. The large bronchial tubes are frequently ulcerated, and passage is thus sometimes afforded to the caseous substances of which the gummata are composed. In view of all the circumstances, it appears that syphilitic gummata of the lung manifest a preference for the region of the hilus, from which they spread from within outwards, toward the deeper structure of the parenchyma. It may, indeed, be questioned if this anatomo-pathological variety of gummatous degeneration may not be regarded as a kind of peribronchic mediastinitis, seeing that, in a state of disease, pulmonary lobules of the fifth and sixth division may be recognized by the naked eye, and only of about the third and fourth in health.

From the clinical point of view, certain important deductions are to be drawn from these considerations. The great difficulty of diagnosis consists in differentiating between lesions which are syphilitic, and those which are tubercular. These lesions are equally distinctive, the physical signs which accompany them are identical, the phenomena of genuine consumption are present—such as broncho-pneumonia, bronchial catarrh, and hæmoptysis—equal in quality and quantity, only

the topographical distribution of the gummata and tubercle is different; for while the former show a preference for the region of the hilus, the latter does for the apex. It is asserted that in pulmonary syphilis hæmoptysis is more rare and less abundant than in phthisis; but this observation is not borne out by reliable experience. Again, in how many instances do patients die of phthisis who have never spat blood?

It is thus evident that in the presence of a destructive centre in the middle portion of the lung there is some excuse for uncertainty or timidity of diagnosis. But if, as almost invariably happens, that in the event of death from syphilitic phthisis, there exist specific lesions in the other viscera, especially in the kidney, in the bones, or on the surface of the body—if these lesions are manifestly recognizable as characteristic of syphilis, if the seat of the pulmonary destruction is other than what obtains in ordinary phthisis, there is almost incontestable proof that the initial stage has been syphilitic. In view of the signal amenability of syphilitic affections to proper treatment, it is obvious that the diagnosis of syphilitic phthisis is of the first importance; and to correct diagnosis may fairly be attributed the rarity of autopsies revealing visceral syphilitic lesions, and the *hiatus* that thus exists in visceral syphilography.

Dyspepsia.

In a very practical address on this subject before the West London Medico-Chirurgical Society (*British Medical Journal*, March 24, 1883), Dr. Hood drew especial attention to those cases of gastric lesion in which dyspepsia played an important part as a symptom, and suggested that, in many cases of so-called simple dyspepsia, there was a definite lesion. The carefully-compiled category of symptoms incidental to ulceration of the stomach suggested that the diagnosis was easy, the very opposite of that being clinically the case. In the early part of 1879, he had placed under his charge a gentleman, aged 40, who had spent many years in the colonies. For eight years he had been a sufferer from dyspepsia, the commencement of which he had attributed to irregularities of diet. He first felt pain over the region of the stomach. Soon he suffered from attacks of vomiting and acid water-brash. Failing to obtain relief, he came to England. When first seen, eighteen months after his arrival, his symptoms were much intensified. Blood was found in his vomit. Presently the stomach became intensely irritable, the patient being supported entirely by means of nutrient enemata. Slowly the grave symptoms subsided, and he regained flesh. In six weeks he went about as usual. Three weeks afterwards, while sitting, on moving suddenly he felt a pain in the stomach, and died within twelve hours. The *post-mortem* examination showed perforation of the stomach at its anterior base. A small healed ulcer, at its base no thicker than tissue-paper, had given way, and the contents of the stomach had been poured into the peritoneal cavity. The stomach, in the immediate vicinity of the pyloric orifice, was honeycombed with the remains of the cicatrices of old ulcers, that presented small depressions corresponding to the position of gastric follicles.

Another patient, whose symptoms bore some resemblance to those of the preceding case, was under his care at the same time. This was a German gentleman, aged 40, who had suffered from painful digestion about fourteen years. In the early days of his illness he had felt pain after taking food. Later, he began to suffer from occasional vomiting. When first seen he was rather emaciated. The stomach usually emptied itself at the end of the day. On several occasions a coffee-colored matter had been ejected, and altered blood was sometimes mingled with the vomit. The stomach descended below its natural limit, and a small lump could be felt in the epigastric region, indicating obstructive disease of the pylorus. Under treatment, flesh was gained, the vomiting ceased, and the stomach recovered its natural size: but the lump remained. Subsequently he went to his business abroad, when the symptoms returned, and he died of exhaustion. Ulceration of the stomach was of very frequent occurrence, but the symptoms of ulceration varied very greatly. Although hæmorrhage was an important symptom, it was not judicious to wait for the presence of blood before inferring the existence of ulceration. In treating assumed ulcer, the patient must be kept in a recumbent posture. Where there was much enlargement of the stomach, Dr. Hood generally used a counter-irritant, and he freely prescribed the various preparations of opium in those cases where there was no doubt that the dyspepsia did not arise from hepatic engorgement; it not only stimulated the bowels, but also made the patient less intolerant of restraint. Where the presence of ulceration was well marked, such treatment should be resorted to as would be insisted on if the ulcer occurred on the surface of the body. In the case of a lady, who at the time of first seeing him was afraid to take the simplest food, and in whom there was found in the epigastric region a spot very tender on pressure, he ordered her to bed, recommended rich milk and light broth as diet, and prescribed six drops of laudanum every four hours. Iodine was suggested as a counter-irritant. A simple soap-and-water enema was to be used every other day.

From the first, the patient's progress was satisfactory. She left her bed in fourteen days, and recently he received a letter stating that she was quite well.

Dr. Daniel said that three or four years ago he attended a gentleman who had acted as a special artist for a newspaper during the Franco-German war. He was a fine muscular man, but had contracted indigestion. He gave calomel and colocyth, but the symptoms increased, and the patient eventually died of exhaustion.

Dr. Schacht suggested that in addition to rest, an enema every other day was important. Constipation was an awkward symptom, and the enema, by relieving the stomach, allowed the opium to do its work.

Dr. Campbell Pope said that he overcame constipation with bismuth in conjunction with belladonna.

Dr. Orton said that he knew of a practitioner who had symptoms of ulceration for thirty-five years, and who at last collapsed from vomiting. The *post-mortem* examination revealed ulcers in all stages.

Dr. Hood, in reply, suggested that marked dyspepsia required the most careful examination, for early diagnosis was very difficult. The ulcers were really boils of the stomach, resulting in choked glands. He was strongly of opinion that dyspepsia demanded vigorous treatment.

Pathology of Bright's Disease.

More than once the opinion has been promulgated that the pathogenesis of the different forms of diffuse nephritis are in so far all alike, as the inflammatory process always starts from the parenchyma, viz., the epithelium of the glomeruli and of the uriniferous tubes. To decide the question, Dr. Aufrecht, in Magdeburg, has instituted a number of experiments. First he ligated one ureter. In this series of experiments* he was able to demonstrate on kidneys, the ureter of which had for some time been ligated, that in the beginning the epithelium alone was affected, by becoming granularly opaque, and by throwing off fibrinous casts. During the first few days, the interstitial tissue continued intact; on the fourth day the capsules of Malpighi were commencing to enlarge, which the interstitial spaces began to do at the same time, nuclear swelling of the local cellular tissue being in either case the cause of the enlargement. The walls of the vessels also became thicker, and mainly in consequence of the swelling of the cells of the adventitia and of the muscular fibres. The epithelium of the uriniferous tubes shows synchronously another alteration; it changes to small pale cells with plainly visible nucleus, but it is not destroyed. While the lumina of the tubules become narrower, the interstitial spaces enlarge continuously in consequence of nuclear swelling and augmentation of cells.

In such a manner A. succeeded in bringing about a morbid process, beginning with affection of the parenchyma, followed by inflammation of the interstitial tissue. The cause is undoubtedly the chemical change in the epithelium, which induces the alteration of the parenchyma. While he was so fortunate as to produce a true interstitial nephritis with preceding disease of the epithelium, his experiments would not as yet have been decisive, had he not been able to show as final consequence a cirrhotic or atrophic kidney in which the process began with a lesion of the epithelium. And A. really has succeeded in producing by the subcutaneous injection of small quantities of cantharidin (0.0025 pro dosi) suspended in oil, all the different forms of nephritis, viz: the so-called acute parenchymatous, the diffuse parenchymatous, interstitial, and the cirrhotic or atrophic kidney, the latter being characterized especially by irregular, deep contractions (or drawn-downwards) of the surface of the organ; these contractions (similar as in cirrhotic liver) were varying in size, and between them the less affected tissue of the kidney appeared prominent. These elevations were sometimes not larger than a pin's head.

All these alterations had the same pathogenic cause, with the only difference that the most pro-

* Pathologische Mitth., 1 Heft., p. 11, and Cbl., 1878, No. 19, and Die diffuse Nephritis, Berlin, 1882.

gressed stage—the cirrhotic kidney—is in direct relation to the most frequent application of the drug employed. Generally the most vigorous animals withstood the largest number of injections; but the accident favored A. in as far as one of the most vigorous female rabbits, which had just concluded its lactation, died already after one injection of the quantity of cantharidin mentioned above, of acute parenchymatous nephritis. Mostly strong animals did not succumb until the kidney-lesion, after a number of injections, had progressed to the later stages; and it was usually in weak and small animals only that the beginning lesion could be studied and followed up without bringing about the death of the animal in a different manner. First, the capsular epithelium began to swell, and the glomerulus was thereby pushed away from the wall. The epithelium of the tubules becomes turbid, swells and contains brilliant formations all over the cell; if on the basis, then the cell is pushed away from the membrana propria. Out of these brilliant formations (bright, shiny) the fibrinous tube-casts are formed—the same process as noted after ligation of the ureter of one kidney. But that this was not only a disturbed nutrition of the epithelium, caused by the cantharidin, was proven by the following parenchymatous interstitial nephritis, where the epithelium of the tortuous tubules was changed in a higher degree than than of the straight ones. Nowhere was wanting in the uriferous tubes an epithelial cell. The epithelium of the capsular wall and of the glomerulus was not so much swollen in this stage, but often partly destroyed. The vascular theory of Cohnheim cannot be considered as wrong, after this, because the capillary vessels mostly were found to contain very little blood, the swelling mentioned of the epithelium narrowing the caliber of the vessels and preventing the passage of the blood, and white corpuscles were never noted to extravasate.

The scientific explanation for the process described is, that in consequence of an affinity, to us unknown, of the cantharidin to the epithelium of the kidney, a chemical change takes place in the latter which later affects the interstitial tissue, the last consequence of the morbid process being the cirrhotic kidney.

A Case of Acute Yellow Atrophy of the Liver.

Dr. D. van Haren Noman, in *Virchow's Archiv.* Bd. xci. H. 2 p. 334, describes a case of acute yellow atrophy of the liver. C. R., unmarried, seamstress, came on the 11th of March, complaining of a feeling of malaise, some epigastric pain, headache, coated tongue and failing appetite—in short, the symptoms of an ordinary gastric catarrh. Two days later the patient was decidedly jaundiced, but the previous symptoms had ameliorated. Physical examination revealed nothing unusual, and especially was it noted that the liver dullness was normal. The urine, although bile-stained, contained neither albumen nor any morphological products. The symptoms were those of catarrhal jaundice. On the 25th, the aggravated nature of the case became apparent. The patient at first became somnolent, and this deepened into coma, from which she could not be aroused. She lay with half-opened eyes, pupils

reacted feebly, and now and then short tetanic spasm of the arms, less frequently of the face and limbs, were apparent. The urine was dark-colored, and contained besides biliary coloring matter and salts, albumen and leucen styrosin. The height of liver dullness amounted to 7 cm ($2\frac{3}{4}$ ”) in the mammillary line, and reached 2 cm ($\frac{3}{4}$ ”) to the left of the linea alba. The temperature was 36 C. (96.8 F.) pulse 57, respiration 16. The symptoms continued with some fluctuations in temperature until the morning of the 28th, when death occurred, seventeen days after the beginning of the attack;

At the autopsy, 10½ hours after death, the following conditions of the liver were noted: Breadth of the right lobe, 145 mm. ($5\frac{3}{4}$ ”); of the left, 92 mm. ($3\frac{5}{8}$ ”); the height of the right lobe, 146 mm. ($5\frac{3}{8}$ ”); of the left, 89 mm. ($3\frac{1}{2}$ ”). The maximum thickness of right lobe was 61 mm. ($2\frac{3}{8}$ ”). The capsule was smooth and shining. On the upper side were seen here and there small and larger yellow spots, which were more numerous and larger on the lower part, the rest of the surface being reddish-brown. Upon section, these yellow spots were noticed through the entire parenchyma. The boundaries between the red and yellow parts were not always sharply defined. The consistence of the liver was soft, and in shape it was very flat, with thin, sharp edges. Microscopical examination of the yellow parts revealed large, granular, cloudy cells, only in some cells small fat kernels were to be seen. There were some strongly refracting bodies, which stained deeply in the borax-carmin. The interstitial intra-lobular connective tissue was broadened and composed of a fine fibred, finely punctate tissue. In the places where the red and yellow substances joined, cellular remains were found, in which sometimes no nuclei and again remains of nuclei appeared. There was a finely punctate connective tissue stroma, in which spaces and alveoli were evident. In some of the red tissue parts, the section resembled an angioma; being composed of spaces filled with white and red blood-corpuscles, and containing small residues of liver cells, either with or without nuclei. In the red spots corresponding to the inter-lobular connective tissue were seen ramifying arteries and veins, and in the tissues rare cylindrical cell masses, and small-celled infiltration, especially near the vessels. He thinks the red atrophy is a later stage of the yellow, and not that both are the results of two different processes.

Face Presentation.

In the *Brit. Med. Jour.*, Dr. Strachan, of Sunderland, writes: “A. W., aged twenty-two, primipara, at full period, was first seen after slight dilatation of os had taken place, the face having barely engaged the pelvis, although the membranes were ruptured, and the liquor amnii was escaping. The finger touched the right malar bone and orbit. The pains were frequent but not strong, and the patient was hysterical. I gave opium, and left her, and was sent for twelve hours later, when the os was fully dilated, and the face, which had now descended to about the middle plane of pelvis, was found presenting, in the first position, the right oblique diameter,

with chin backwards towards right sacro-iliac-synchondrosis. As the forehead seemed decidedly to take precedence, I tried gently to make the head rotate on its transverse axis into the first cranial position, with the occiput towards the left ilio-pectineal eminence, but did not succeed. This was the method recommended by the late Dr. J. Clark, but is now abandoned. Next, introducing my finger into the mouth, I endeavored to bring down the chin—the proper analogue of the occiput—at the same time assisting the natural rotation into the fourth facial position—the left oblique diameter, with the chin forwards. But all my efforts seemed fruitless to move the head in any way, especially as the pains were weak. So, after waiting two or three hours longer to see what course nature intended to adopt, and as the fronto-mental diameter still remained impacted in the same position, I gave chloroform, and applied the long forceps with double curve; the upper blade, which had to be introduced first, being rather difficult of introduction between the prominences of the face and the maternal parts, so as to avoid injuring either. The long straight forceps are recommended in these cases with the view of better assisting rotation, but in this instance the double-curved ones answered remarkably well, as under rather powerful traction, accompanied by a gentle twist in the desired direction, rotation took place into the fourth position, and the face was born chin forwards, the hollow of the forceps pointing backwards. Had rotation not taken place, the case would most likely have ended in craniotomy. The child was born alive, and although slightly disfigured at the time, with the caput succedaneum over the right cheek and orbit, which were both considerably swollen, it has done well; the mother has also made a good recovery."

The Essential Nature of Diseases of the Heart.

The *Med. Times and Gaz.*, March 17, 1883, says: M. Martin, in an elaborate paper on the pathogeny of heart diseases, in the *Revue de Médecine* for February, 1883, divides all heart affections into two groups, viz., those of valvular origin, and those of vascular origin. These groups resemble each other in that each has an acute and a chronic stage, the latter being almost always a consequence of the former; in both groups, too, the original lesion—whether it has a chief valvular focus, or whether it depends upon a number of minute vascular foci—may be the starting-point of a twofold inflammatory process, partly muscular and partly interstitial. The former process is always compensatory. As regards the latter, whether the process has commenced in one of the valves and spread thence to the muscular wall of the heart, or whether it has commenced as a periarterial lesion, is a matter of little moment, for the ultimate result is the same, viz., diminution of the power of the heart, and finally astylosism. But, granting that no hard and fast line can be drawn between the two groups, or even that ultimately it should be shown that all lesions of the heart have their origin in some vascular change, still M. Martin thinks that his proposed classification might be retained with advantage, as corresponding with unquestionable differ-

ences in the etiology and mode of evolution of these changes.

Practical Applications of Koch's Discovery.

From the *British Medical Journal*, March 3, 1883, we learn that Dr. Gairdner, of Glasgow, is of opinion that the practical applications of Koch's discovery are to be looked for chiefly in two directions. First, in that of prevention. "This discovery," he remarked at the Glasgow Medical Society, "imposed on medical men the necessity of looking to the observance of the most scrupulous cleanliness. They must have clean hospitals, clean wards and walls, clean rooms and floors. More than ever must this now be the order of the day. They must keep in view that no man was safe unless he got everything round him as clean and as pure as could possibly be managed. Another possible direction in which what they had learned might be applied (though the question was so obscure that probably even Koch would not push it), was in making experiments to ascertain whether the tubercle-bacillus could be cultivated into a milder form. Were this possible, the question might arise whether, as in the case of small-pox and anthrax, the milder form might be utilized as a prophylactic against the more virulent form. In the matter of cure, too, attempts must be made to apply the discovery. For the next year or two, there would be a run on the indiscriminate use of antiseptics in the treatment of phthisis; and probably this would result in disappointment. But this ought not to discourage them, as they might feel sure that, whatever residuum of utility there existed in the antiseptic treatment of phthisis, would eventually be made clear."

Chronic Diphtheria.

In the *Berlin Klin. Woch.*, Dr. Wall reviews twelve cases of chronic diphtheria. He says the course of the disease is different in the pharynx; the membranes are not removed there so soon as from the tonsils, and there is a constant source of contagion. If the secretion is profuse, the disease cannot be overlooked, but that is not always the case; he had twelve cases where his rhinoscopic examination revealed the nature of the discomfort. Large ulcers and destructions were detected. Impaired hearing and pain in the eyes have caused an examination. There was always a pain in the eye, generally on one side, spreading over the head, especially when true ulcer was at the basis of the cranium. The ulceration resisted sometimes every treatment, and came down to the soft palate and even the œsophagus. Local complaints became very severe sometimes, with a general debility without fever. The ulcers were similar in character to those of syphilis or tuberculosis. Dr. Wall says diphtheria gets its most destructive character in cases where hereditary syphilis, scrofulosis, or tuberculosis could be traced.

The treatment is tedious; a solution of carbolic acid, five to eight per cent, powdered iodoform, and boric acid, are the best remedies, assisted by the frequent use of the nasal douche. These strong solutions must be used strictly at the place; weaker solutions might be used in the atomizer. The anti-syphilitic treatment in doubtful cases must always be postponed.

The Cure of Strabismus by Glasses.

The *Practitioner*, March, 1883, says that M. Boucheron (*Annales d' Oculistique*, December, 1882), recommends the use of corrective glasses in cases of convergent strabismus, an affection that is usually associated with hypermetropia or long-sightedness. The employment of appropriate corrective glasses must, however, be preceded, as Green recommended long ago, by the instillation of atropine to paralyze the accommodation, and the effect of the atropine should be continued for two or three months, if the case is seen at the outset; or for ten or twelve months if the affection has lasted some time. In fact, the employment of the atropine should be continued as long as there is any tendency to strabismus. The glasses ordered should be of sufficient strength to neutralize completely the hypermetropia present. When no further tendency to strabismus is observed, the atropine may be discontinued, but the glasses must still be employed. The strength of the atropine solution he uses is one part of the sulphate to 300 of water. If atropine produces any irritation, he uses duboisine. When strabismus is fairly established, he resorts to tenotomy, but even after this is performed, he instills atropine.

Hernia Reduced by Electricity.

The *Practitioner*, for March, 1883, says that Dr. Suprunenko mentions an experience of interest in the *Wratsch* (No. 17, 1882). A right inguinal hernia, strangulated for three hours, had resisted half an hour's taxis. A moderately strong induction current was then tried; the positive electrode being pressed against the tumor, while the negative was applied first against the lumbar vertebrae, afterwards over the umbilicus. The hernia at once began to diminish, and in less than two minutes disappeared entirely. Another case is given in the same journal (No. 40, 1882). An old man of eighty had suffered from a strangulated hernia for twelve hours. Persistent taxis had altogether failed, though Dr. Pergamin kept it up for over two hours. The induction current was then used for fifteen minutes, the pole being applied to various parts of the tumor, but this also failed. The current being still maintained, he again attempted manipulation, and in two minutes the bowel returned into the abdomen with a gurgling noise. (*Centralb. f. Chirurgie*, Dec. 9, 1882.)

traits of some notable men of those times. "The National Academy of the Arts of Design," by Benson J. Lossing, gives a vivid description of the trials of New York artists in establishing their National Academy, telling how much they owe to S. F. B. Morse, who is seldom associated with the Arts of Design in the mind of the general public. The short sketches of the artists, Durand, Ebers, and Cummings, add much to its interest. The sketch of Anthony Trollope, with its fine portrait, the article on the Brooklyn Bridge, and the Middle Colonies before the Revolution, are all of much interest. The short stories are good, as usual, and John F. Weir's Art Study at Home and Abroad should be carefully read by all art students. Not the least valuable of its contents is the Editor's Easy Chair and Literary Record.

—The *Agriculturist*, much improved artistically, and in many other respects, is a necessity for the farmer's family, and its price puts it within the reach of those of the most moderate means. Price \$1.50 a year.

—*Littell's Living Age* is certainly the very best of all weeklies. No other publication can supply its place. It contains not only the best solid literature, but also the best serials of the day. For readers of limited leisure and purse, it is the most available means of possessing themselves of the very best current criticisms, philosophy, science, and literature, at the very reasonable price of \$8.00 a year.

—*Harper's Weekly*, which stands first of all illustrated papers, has become a necessity to every intelligent family. The illustrations, by the best artists, are unequalled by those of any other paper in the country. Price, \$4.00 a year.

—We would recommend as religious newspapers, the *Independent*; the *Evangelist*, of New York; the *Presbyterian Banner*, of Pittsburgh; *Christian Advocate*, of New York; *Zion's Herald*, of Boston, and the *Presbyterian*, of Philadelphia.

—Of family newspapers, the *Germantown Telegraph* is unsurpassed, and in many respects, the *Vermont Journal*, published in Windsor, Vt., is equally good. They should be in every family of the country. Full of interest to old and young, and free from everything the youngest member of the household might not read, they are the model newspapers of the day.

—For lively and interesting social news and talk, *Progress*, by Forney, is one of the most charming of weeklies. Other regular and valuable exchanges are the *Trenton Gazette*, and *Cincinnati Gazette and Commercial*.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—*Harper's Monthly*, Harper & Brothers, New York, for May, is before us. We cannot say unusually attractive, for *Harper* is always first of the monthlies. This number has an exceedingly attractive description of San Francisco, finely illustrated. The second of the series of historical articles, "The Treaty of Peace and Independence," is extremely interesting, with well-executed por-

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE EFFECT OF SALICYLATE OF SODIUM ON
THE HEART.

The question, what effect preparations of salicylic acid have on the heart, is still not solved; experiments instituted to decide it having given contradictory results. According to some, the systolic action of the heart is strengthened; according to others, weakened. We only need to refer to the investigations of Bartels, Welyki, Boche-fontaine, Köhler, Danilewski, Oltremare, Cattani, Chorone and Petrucci, and to the chapter of Liebermeister* in V. Ziemssen's Cyclopædia. The latter seems to be of the opinion that the effect is a depressing one, as he mentions at the end of his article that he does not prescribe salts of salicylic acid to patients with a weak heart.

Prof. Ed. Maragliano, Director of the Clinical Institute in Genoa, has recently taken up the subject again, and instituted in the interest of practical therapeutics a series of investigations, the results of which are rather interesting, and seem to decide the question finally.†

Three different kinds of experiments were made by the assistants of Maragliano under his direction.

The first concerned persons to whom the salicylate of sodium was given for several days consecutively. The curves of the pulse were noted with the sphygmograph during and after the use of the remedy every morning and evening.

The second series were individuals in whom the curves of the pulse were noted before and after a single doses of salicylate of sodium of about 75 grains (5 gramm).

The third series embraces persons in whom the arterial pressure was determined after Basch's method, before and after the administration of a single dose of the same remedy of about 75 grains.

These investigations gave the following results:

1. Salicylate of sodium, if administered for a number of days *in refracta dosi* causes a progressive increase of strength of the beat of the pulse, and the systolic line becomes progressively higher.
2. After a single large doses there was observed,

* Vol. I., pt. 2 and 3, page 74.

† Centrbl. f. d. Med. Wiss., 48, 82. Page 865.

one hour after the administration of the remedy, an augmentation of force of the beats of the pulse, and the systolic line ascended higher; two to three hours later this effect had reached its maximum, and disappeared three to five hours later. The normal dirotismus usually becomes accentuated. Sometimes the pulse becomes tricrotic.

3. The intra-arterial pressure increases about an hour after the administration of a single large doses, and becomes again normal about three hours later. The increase varies between ten and twenty mm. mercury.

This triple series of investigations seems to exclude, therefore, all thoughts regarding a possible depressing effect on the heart of the salicylate of sodium.

Certainly in all these investigations we may take for granted, as no mention is made to the contrary, that the individuals selected for these experiments did not suffer from any organic lesion of the heart. To judge from analogy, as, for instance, of the effect of digitalis on a heart the seat of some lesion, we would infer that the action of salicylic acid and its salt is always a stimulating one, and therefore the remedy contraindicated, whenever the impulse of the heart is already too powerful. It should not be administered in hypertrophy, nor in diseases like meningitis, where, in the beginning, at least, the heart is over-acting, if anything. Whenever we wish to depress the circulation, salicylic acid is contra-indicated.

PROSTITUTION.

An evil, undoubtedly, yet it would seem in the light of human morality to be almost a necessary evil. Legislation has been from time immemorial impotent to eradicate it, while the older countries, as the result of centuries of experience, have given up the effort, and direct their legal enactments rather towards keeping it within bounds than to do away with it.

As its regulation, in our new country, constitutes a question of paramount importance, we may derive some valuable hints from the following, which we take from the *Medical Press*, March 21, 1883:

Dr. Moriz Kraus, Secundararzt of the Royal Krankenhaus Wieden, Vienna, recently published an article in the *Wiener Medizinische Zeitung* on the above subject. From it we learn that some time between the years 1860 and 1870 a health-book was introduced as a check upon the spread of venereal diseases. Every registered prostitute possesses one. On the one hand, its possession is an indisputable legitimation, and on the other, a tolerably perfect means of control on the part of the authorities. The book contains (a) the nationality of the person to whom it refers, together with her signature; (b) residence; (c) name and residence of the examining physician; (d) the examiner's decision as to her state of health. Section 1 explains the intention of the health-book, which is to show proof of her having undergone regular and satisfactory medical examination. Section 7 fixes the remuneration of the examiner at 1s. at the examiner's own house, 2s. at the prostitute's. Section 8 provides that, if the prostitute on examination be found sound, the fact, together with the date of the examination, be entered in the book; but if, on the other hand, she be found to be suffering from any affection of the genital organs, or from any contagious disease, the examiner is empowered and required to detain the book. He is then to offer her her choice of the three Royal Krankenhäuser, and in case of her refusal to enter any of these, she is to be detained in a hospital by the police. Finally, she is to be sharply warned that, if she still pursues her calling, a penal prosecution will be the result. Treatment of such cases of venereal disease at the prostitute's residence is unconditionally forbidden. There is finally (e) a tabulated appendix, which contains the condition in which the possessor of the book was found, the date of the examination, and the signature of the medical examiner. By means of this the police commissary has proof at once that the bi-weekly examinations are regularly submitted to in accordance with section 2 of the health-book. Dr. Kraus proposes to render the book more complete, and less liable to abuse, by affixing to it the photograph of the prostitute to be renewed every three years, her age, and finally a small appendix of instructions on the nature and symptoms of the various maladies to which she is, by her calling, of necessity exposed. He cannot help mentioning an interesting circumstance, viz., that of late syphilis has occurred with the lowest possible frequency in the syphilis divisions of the three Krankenhäuser, and he attributes this *erfreuliche Thatsache* on the one hand to the health-book, and on the other to rigorous control on the part of the police.

ACCIDENTS PRODUCED BY LUMBRICI.

At a recent meeting of the Société de Thérapeutique, a member mentioned a case where a large number of round worms were found in the hepatic ducts, and several encysted in different parts of the liver.

The patient was a little girl, five years of age, who was brought to the hospital in an alarming

state, presenting choleric symptoms. The physician learned that the child had passed three round worms, but did not pay any particular attention to the circumstance. The child succumbed three days later. At the autopsy a perforation of the stomach and general peritonitis was discovered; several lumbrici were found in the abdominal cavity. Very little attention is paid to lumbrici at Paris, as the water in common use is filtered, and worms are not often found. M. Archambault recalled a curious case which occurred in his practice. Three children, newly arrived in Paris, after partaking very freely of spiced cakes, were suddenly seized with alarming symptoms, one with convulsions, another with very painful colic, and the third with diarrhoea and vomiting. As the matters vomited contained several lumbrici, santonin (20 centigrammes) was given, and caused the expulsion of a large number of worms.

It is evident that in these cases, the alarming symptoms were induced by the violent reaction of the worms, irritated by the spiced food.

Many cases of arthralgia in children are due to the presence of lumbrici, and the pains disappear on the administration of santonin.

THE PROPER WAY TO USE IODOFORM.

When an antiseptic is employed in the treatment of wounds, the form or manner in which it is used is generally considered of little importance. M. Wiskemann, in a memoir in the *Berliner Klin. Wochenschrift*, mentions the recent experiments of Koch, which prove that carbolic acid dissolved in alcohol or oil has no deleterious action on the malignant charbon germs. He himself affirms that it is by no means a matter of indifference whether iodoform be applied over the surface of an ulceration, specific or otherwise, in form of crystals, as an amorphous powder, dissolved in ether, or as an unguent.

Iodoform acts, not only as a chemical combination, allowing the escape of iodine in a free state; it has also certain mechanical properties. When the surface of a wound is covered with a layer of iodoform in crystals, a certain degree of absorption of the liquids secreted takes place. These

products of secretion, penetrating the interstices between the minute crystals of iodoform, soon lose the liquid form, and produce with them an impermeable crust. Under this crust, cicatrization soon occurs, without any retraction of the tissues. Iodoform should then, according to this author, be employed in the form of crystals when used as a dressing for wounds, or for ulcers, syphilitic or otherwise.

TREATMENT OF SYPHILIS COMPLICATED WITH MALARIA.

Malaria is not, perhaps, a frequent complication of syphilis in this country, but the treatment employed in such cases by Sigmund will, without any doubt, prove applicable in many cases occurring in our large cities, where the individuals are, to use a common expression, considerably run down.

The essentials of treatment are as follows: 1. Each morning rub into the groins or elsewhere, five grams of mercurial ointment. 2. At bed time the patient will take two pills, prepared according to the following prescription:

R.	Ac. arsenious,	gr. ij.
	Ferri protochlorid,	gr. xv.
	Quiniæ sulph.	gr. xlv.
	Ext. gentianæ,	q. s.

Et. ft. pil. No. 100 of three grains each. Augment progressively the dose from two to six pills.

PARIS HEALTH REPORT.

M. Du Castel, at a recent séance of the Soc. Medicale des Hopitaux, presented his report on the reigning diseases during the last quarter of 1882.

The general mortality was rather elevated, as there occurred 4,247 deaths instead of 3,146, the average for the same quarter during the preceding ten years. About 21,000 patients were received into the hospitals.

Pneumonia and pleurisy were less frequently observed, and were of less gravity than usual, while pulmonary phthisis caused a large increase of mortality.

303 cases of diphtheria were received in the hospitals, with 188 deaths; in the city 432 deaths from the disease were noted.

There was a marked remission as regards typhoid fever. The cases were not so numerous, and were of less gravity; the mortality 13 per cent.

NOTES AND COMMENTS.

Bacillus Mounting.

In the *Med. Press*, March 28, 1883, Dr. F. J. B. Quinlan thus describes what he considers the best method of preparing tubercular bacilli for the microscope. Take a button of phthisical expectoration in an advanced case—the first expectoration in the morning is the best; pour upon it a few drops of liquor potassæ, and work it with a glass rod until it becomes a homogeneous fluid. Put a drop of this fluid upon a microscopic cover-glass, from .006 to .004 thick, and allow it to dry. Now pass it lightly through the flame of a spirit-lamp, filter upon it a few drops of magenta aniline solution, and let it lie for twenty minutes. Place it in a mixture of one-third nitric acid and two-thirds of distilled water until it bleaches, which will take about five minutes, and wash it with water. Next drop upon it a little methyl blue solution, and let it stand for five minutes; and finally get rid of all aqueous fluid, by dipping it in absolute alcohol. To mount it, put a small drop of Canada balsam and benzine upon a glass microscopic slide, and put the cover-glass on it with the bacillar surface immersed in the balsam. This will soon harden, and will preserve the preparation indefinitely. The plan depends upon the fact that once the bacilli are stained red they cannot be decolorized by the nitric acid, which bleaches everything else; it is much facilitated and hastened by doing it at a warm temperature. By this method the bacilli are seen scarlet, and the other elements of the sputa blue. The bacillus is about one-third the size of a red blood corpuscle, and requires a power of at least 500 to exhibit it satisfactorily. The process is delicate and a little tedious; and from my own laboratory experience of it, I doubt if it will become a clinical test in general practice.

Cancer of the Ileum.

In the alimentary canal malignant growths are most frequently found in the buccal cavity, respectively, tongue, etc., in the œsophagus, stomach and rectum. But that also other parts of the intestines, and especially the ileum, may oftener suffer from this complaint than many imagine, we

learn from the report of Dr. Du Castel (*Archives Générales de Médecine*, 1882, ii. 7.)

The cancer of the ileum has its origin in the lowermost end of the small intestine, near the Bauhin's valve and its near neighborhood. Experience has shown that it may be limited to the valve alone, which latter then loses its elasticity, and is changed into a solid plate, by which the locomotion of feces is prevented, and sometimes totally ceases. In case the cancerous masses break down during the course of the disease, the passage is again open, and diarrhœa instead of the former constipation becomes the rule, as is always the case whenever any inflammation exists near the ileo-cœcal valve, which does not totally occlude the opening. Upwards this cancer rarely spreads further than 5 to 10 ctm., but if of long duration it will extend to neighboring tissues, the peritoneum, lymphatic glands, and especially the colon. The primary seat, however, of the carcinoma, in such cases, is always the ileum, and so all cancers in the intestines are at the end of a segment: cardia, pylorus, rectum.

The Curability of Cerebral Aneurism.

Dr. James Grey Glover reports an unusual and interesting case in the *Lancet*, March 31, 1883. Nine years ago the patient had an aneurism of the internal carotid artery, which ruptured, the extravasated blood was absorbed, and she recovered. After nine years a second aneurism developed near the old one, just as the vessel leaves the carotid canal at the base of the brain, within the cranial cavity, of course. The only symptom she had during her illness was paralysis of the third cranial nerve. She was perfectly well until three weeks before her death, when she was taken sick. She suddenly became unconscious, and remained so for twenty minutes. She came out of this, and the attack passed off, leaving only ptosis, dilated pupil, and strabismus. Ten days later she had another attack, similar to the first, but more severe. From this attack she rallied, but the third attack followed. She became suddenly unconscious, and remained so fourteen hours. The autopsy revealed the aneurism which had ruptured, and the obliterated sac of the old aneurism which ruptured nine years ago.

Muscular Atrophy Following Affections of Joints.

The occurrence of a case, where in a young man after a contusion of the right knee-joint debility and atrophy of the quadriceps m. of the same side followed causes Charcot to discuss the fre-

quent appearance of such lesions after affections of joints, especially of a surgical character, in the *Progrès Méd.*, 1882, Nos. 20 and 21. Most authors are of the opinion that in consequence of the sensory nerves being irritated by the affection in the joint, in a retrograde manner, a change takes place in the place of origin of the motor and trophic nerves in the spinal cord. They are "dynamic" disturbances without deeper lesions; the electrical treatment, therefore, is usually followed by recovery. Charcot seems to confirm this idea, and mentions that the reaction of the atrophic muscular structure to the electrical irritant is quantitatively only decreased. Reaction of degeneration, as noticed in cases of muscular atrophy due to morbid organic changes in the motor nerves or in their centre in the spinal cord, is never observed in the cases in question. Charcot also lays stress on the fact that the electrical spark of an electrical machine induces very strong and energetic contraction in such muscles, which respond very feebly only to the stimulus of the induction coil or of the constant current.

On the Connection Between Disease of the Eye and Affections of the Sexual Organs in Females.

Dr. C. E. Fitzgerald read a paper recently on this subject (*Med. Times and Gaz.*, March 24, 1883). He related a case in which a violent neuro-retinitis occurred some time after a sudden cessation of the menses. The vision improved under treatment, and with the reappearance of the menses. In a case of disseminated choroiditis with floating opacities in the vitreous, multiple fibroid tumors of the uterus were found; and it was suggested that possibly these tumors affected the circulation, so as to react injuriously on the delicate vascular tissue of the eye.

Referring to masturbation, he thought that the habit was practiced by females much more frequently than was generally supposed, and mentioned three cases in which he believed it had acted most injuriously upon the eyes. He considered the subject one of grave importance; and that, however unpleasant it might be, it ought to be thoroughly investigated. He believed that the majority of cases of asthenopia in young women which were not benefited by glasses were due to this cause.

Osteoma of the Corpus Striatum.

We frequently note cases where persons since childhood had a paralyzed limb, the nutrition and development of which never progressed since the time the lesion first made its appearance. The

usual history of such cases is, that the individual, when in his earliest childhood, became suddenly sick with fever and irregular pains, when, mostly after a day or two, without any apparent cause, the gradually increasing helplessness of the affected limb becomes apparent. It is rare that we have the opportunity of recording after the death of the person the pathogenic morbid condition, and two cases, therefore, reported by Dr. A. Bidder in Virchow's *Arch.*, lxxxviii., p. 91, are of decided interest. At the post-mortem of one of these cases, that of a man *æt.* 39, who since his childhood had suffered from paralysis and contracture of both extremities on the right side, the development of which had also continued in *statu quo*, an irregular shaped bony body was found in the substance of the left corpus striatum. The microscopic examination revealed it to be an osteoma. B. gives besides the history of a case, where the individual is still alive, and where exactly the same pathological condition exists, and also since early childhood.

Atropia for Ear-ache.

The *Boston Jour. of Chemistry* says that Dr. A. D. Williams recommends its use as follows:

The solution is to be simply dropped into the painful ear, and allowed to remain there from ten to fifteen minutes. Then it is made to run out by turning the head over, then being wiped with a dry rag. The solution may be warmed to prevent shock. From three to five drops should be used at a time. The strength of the solution must vary according to the age of the child. Under three years one grain to the ounce, and over ten years four grains to the ounce of water. In adults almost any strength may be used. All ages will bear a stronger solution in the ear than in the eye. The application should be repeated as often as may be necessary. Usually, a few applications will stop the pain. In acute suppurative inflammation of the middle ear and acute inflammation of the external meatus, atropia will only slightly palliate the suffering, but in the recurring nocturnal ear-aches of children it is practically a specific.

Glio-Sarcoma of the Cerebellum.

A case presenting prominently the following symptoms, viz.: 1. The history of a fever, which at first came on periodically; 2. Marked splenic enlargement; 3. Great muscular soreness; and, 4. Incomplete paralysis, was diagnosed by Dr. L. Emmett Holt (*Med. Record*, March 31, 1883,) to be

due to chronic malarial poisoning. The patient (four and a half years old) improved for a week, under the use of quinine (gr. xx. per diem). She grew worse, however, and diagnosis of tumor was made, which the autopsy confirmed. The growth was situated on the inferior surface of the cerebellum. This case teaches that we should not be too ready to attribute obscure nervous symptoms to malarial poisoning, even in patients in whom indubitable evidences of such poisoning exists; and that a failure of full doses of quinine to affect the symptoms should lead to a careful examination for organic disease of the nerve centres.

New Treatment of Phagedenic Chancre.

The treatment proposed by MM. Vidal and Ferrillon against this ordinarily intractable form of the disease, has already proven successful in the hands of other practitioners. The preparations recommended by M. Vidal are the following:

R. Acid. pyrogallie, ʒv.
Vaseline, ʒxx.

M.

This is employed in the treatment of superficial ulcerations without deep sinuses or pockets; for the treatment of the latter form the following powder may be dusted into all parts of the ulceration:

R. Acid. pyrogallie, ʒv.
Amyli pulv., ʒxx.

M.

M. Ferrillon considers the following preparation as better adapted for general use:

R. Ac. pyrogallie, ʒx.
Vaseline, ʒiv.
Amyli, ʒx.

M.

The dressing should be renewed twice daily.

A Prescription for Acute Rheumatism.

In the *Brit. Med. Jour.*, April 7, 1883, Dr. J. Mortimer Granville says: In acute rheumatism, as early as possible in the case, give the mixture described below, in the diluted form in which I have prescribed it. Do nothing else, except to pack the painful joints in wraps of very loose cotton-wool, covered with light flannel; not oil-silk or any other vapor-proof material.

R. Tincturæ aconiti, (P.B.) ℥xij.
Ammonii sulphidi, ℥xvj.
Aquæ menthæ viridis destillatæ, ʒvj.

The dose is a fourth part, every fourth, or, in severe cases, every third hour, until the pain is relieved and the "fever" has abated. The mixture should not be prescribed in larger quantity than will suffice for four doses, on account of the

tincture of aconite, and, more especially, the tendency of the sulphide of ammonium to decompose and deposit sulphur.

Extract of Calabar Bean.

This medicament has been recommended as an heroic remedy in obstinate constipation. Recent experiments undertaken in the service of Prof. Leyden, of Berlin (*Deutsch. Medic. Woch.*), demonstrate that this extract has a very rapid and sure action in atonic states of the intestine, characterized by flatulence, meteorism occurring just after meals, a sensation of weight in the epigastrium, habitual constipation, etc. The medicament was given in this form;

R. Ext. calabar bean, 1 centigram.
Glycerinæ, 30 grams.
M. Et. S.—Ten drops daily.

The patients are greatly relieved, but the benefit is rarely durable, and if the remedy is continued for any length of time, toxic accidents are apt to supervene.

Pruritus Urethrae during Gonorrhœa.

In the *Journal of Cutaneous and Venereal Diseases*, April, 1883, Dr. Wm. L. Axford mentions a most intense itching of the urethra often observed during the third stage of gonorrhœa. All treatment was unavailing until he found that distention of the urethra afforded relief. The passage of a catheter, however, increased the inflammation, so he resorted to the following expedient, which he has found successful. The patient was directed to hold the end of the penis firmly between the thumb and index finger in such a way that no urine can escape, then to make an effort to micturate, thus thoroughly distending the urethra and keeping it so for one or two minutes, the sensations of the patient to be the guide as to the amount of force to be used.

Iodoform Suppositories in Puerperal Septicæmia.

In the *Canada Med. Record*, March, 1883, Dr. Alloway presents the records of six cases of puerperal septicæmia, three of which had been treated by a new method, viz., the introduction into the uterine cavity of iodoform suppositories. In carrying out the treatment he uses a Sims' speculum, washes out the uterus first with plain or carbolized water, and then, with a tent-inserter, passes the suppository far up into the fundus. He uses them of the strength of ten, fifteen, or twenty grains, and usually introduces one night and morning. No poisonous effects have been noted.

Climacteric Dyspepsia.

Mr. Prangley read a paper on this subject before the Norwich Medico-Chirurgical Society. It occurs in women between the ages of forty and fifty. The symptoms are those of great nervous depression, with pain on the top of the head, noises in the ears, hot flushes and chills, with curious sensations in the abdomen. The dyspeptic symptoms are those of præcordial distress, with palpitation, costive bowels, coated tongue, and foul breath. The treatment consists in the administration of bismuth, bicarbonate of potash, and ammonia, adding valerian if the nervous symptoms predominate, followed by quinine, strychnia, and the dilute nitro-hydrochloric acid.

Condensed Milk.

Dr. Richard Neale raises his voice in the *Brit. Med. Jour.*, March 24, 1883, against giving condensed milk to infants. "At times, given medicinally, it is of great value; but, as a food, it is unnatural, and sooner or later the infant must suffer if thus fed. I have in so many instances seen the fatal results of bringing up infants on the condensed milk, that I invariably warn patients against its continuous use. The most robust-looking child thus fed has no vitality, and is frequently cut off by an illness that, under other circumstances, would have proved very trivial." We can corroborate his experience.

Phosphatic Incrustations of Urethra.

Though rare, yet it sometimes happens that, after lithotomy, phosphatic concretions form in the urethra, interfering with micturition and the passage of a catheter. Dr. S. S. Kahn, of San Francisco, reports such a case in the *Medical Record*, March 31, 1883. The perineal wound not having entirely healed, he introduced a catheter and injected two ounces of a one per cent. solution of boro-citrate of magnesia, and gave internally a teaspoonful of this solution every hour. Shortly afterwards, these concretions were passed, in consistence like putty, and in two days the urethra was clear.

The Treatment of Rheumatic Cardiac Complications.

Dr. MacLagan, of London, endorses the views of those who hold that salicin possesses the power of preventing cardiac complications in rheumatism. He considers small doses ineffectual, and recommends twenty to forty grains every hour for six hours, or until relief from pain is experienced; by its early use he thinks we may prevent valvular inflammation. Since *endo-cardial* complications

frequently do not cause any pain, it would be well to incorporate the salicyl compounds in the treatment of *all* cases of rheumatism as a precaution.

Salicylic Acid in Rheumatism and Typhoid Fever.

In the course of a case of rheumatism in a child, related by Dr. J. P. Thomas, of Pembroke, Ky., in the *Louisville Med. News*, March 31, 1883, the author states that the following formula has proved to have so many advantages that he urges the profession to give it a trial.

R.	Acid salicylic,	ss.
	Potass. acetat.,	ij.
	Aque aromatic.,	iv.
	Syr. limonis,	ij.

M.—The usual dose for adult in rheumatism or typhoid fever, one tablespoonful every two or three hours, largely diluted with water.

Salicylic Acid in Typhoid Fever.

M. Valpian (*Med. Press*, April 4, 1883,) prefers salicylic acid to sulphate of quinine. The former was not only an anti-thermic but also an antipyretic. He never found it to produce a deleterious action on the heart, nor arrest the albuminuria which was almost constant in a more or less degree in typhoid fever. He had particularly remarked the absence of bed-sores and the abscesses of convalescence when salicylic acid was administered.

The Poison of Ergot.

In a recent communication read before the Chemical Society of Russia, (*Med. Press*, April 4, 1883), the author, A. W. Pehl, attributes the toxic properties of ergot to putrefactive changes set up during decomposition of the vegetable fibrin of the wheat. The poisonous products of putrefaction, denominated ptomaines, are due to the peptic action of the ergot, which is exerted to a very considerable extent, and so contributes to the splitting up of the elements of flour and their subsequent putrescence.

Fatal Vomiting of Pregnancy.

The *Proceedings of the Medical Society of the County of Kings*, for April, 1883, has a report by Dr. A. H. P. Leuf of a case of death from absolutely uncontrollable vomiting in a single woman aged 22. The autopsy revealed the third month of pregnancy, which condition was totally unsuspected. The moral of this case is to look for pregnancy in cases of inexplicable and persistent vomiting; for, had its true nature been recognized, this girl's life might have been saved.

Indurated Chancre between the Toes.

The *London Med. Record* notes that M. Leloir relates (*Ann. de Derm. et de Syph.*, Nos. 9 and 10, 1882), the case of a medical student in whom the initial manifestation of syphilis was situated between the second and third toes of the right foot. The patient was suffering from eczematous fissures between the toes, and acknowledged contact of the affected part with the lips of a woman who was afterwards found to be suffering from mucous patches of the mouth.

Second Infection with Syphilis.

Though rare, yet it is abundantly established that a man *can* have syphilis twice. Dr. Taylor presented a case to the New York Dermatological Society (*Jour. Cut. and Ven. Dis.*, April, 1883,) which adds another to the proof cases. The patient had a chancre in 1874, followed in two months by large elevated red blotches all over the face. The second chancre was contracted in 1881. In both attacks he had roseola, papular eruption, crusts on scalp, alopecia, and iritis.

Pencils of Sulphate of Zinc.

A demand having arisen for the above in ophthalmic practice, the *Pharmac. Zeitung*, February 28, 1883, says that they may be prepared by melting ordinary crystals of zinc sulphate in a porcelain dish in their water of crystallization, and then very quickly pouring the liquid thus obtained into cones of wax paper, similar to those used in the preparation of bougies.

Coffee in Typhoid Fever.

Recently Dr. Guillassee, of the French Navy, has given coffee in the early stages of typhoid fever with marked success. Three teaspoonfuls were given adults every two hours, alternating with one or two teaspoonfuls of claret or Burgundy wine. A beneficial result was immediately apparent.

Cauterization of Clitoris for Hysteria.

In neuropathic females, Dr. N. Freiderich (*Virch. Arch.*, vol. xc.) believes that an over-sensitiveness of the sexual organs, acting upon the spinal and cerebral centres, may cause hysterical symptoms. He has treated eight such cases by cauterization of the clitoris, and, though a painful operation, every case has been ultimately cured.

The Cold Douche.

Dr. W. H. Broadbent reports in the *Lancet*, March 24, 1883, a case of delirium tremens in

which the nervous system failed to respond to drugs, and where the patient was reduced to the last extremity, and one case of sleeplessness and pyrexia after child-birth, both cured by the cold douche.

Iodoform in Laryngeal Ulcers.

Schrötter, of Vienna, says that in many thousands of cases of tuberculous ulceration of the larynx, he has never seen iodoform do any good. Some of our correspondents have found it to answer admirably in diphtheritic complications.

The Period of Incubation of Measles.

Dr. W. E. Green writes to the *Brit. Med. Jour.*, April 7, 1883, corroborating the statements of Mr. Vacher, and citing many illustrations to prove that the period of incubation in measles is fourteen days.

Hyperidrosis of the Hands and Feet.

The *Druggist* recommends moistening the parts once or twice daily with a mixture of naphthol 5 parts, glycerine 10 parts, and alcohol 100 parts; after which they are to be dusted with a mixture of naphthol and starch 2 parts to 100.

Supposed Hydrophobia Treated by Chloral.

Dr. W. H. Broadbent reported to the Clinical Society of London (*Brit. Med. Jour.*, March 3, 1883), four cases of supposed hydrophobia, treated by chloral, one of which recovered.

NEWS AND MISCELLANY.**The Struggle for a Living.**

The following is taken from the presidential address to the Maine Medical Association by the late Wm. Warren Greene, M. D. (*N. Y. Med. Record*, March 24, 1883):

"Witness the large number of doctors in every city struggling for mere existence, and see how few out of the whole number really do the work. See how in almost every country village a full practice for one or two good men is piece-mealed by sharp and often acrimonious competition, to the detriment of all.

"It would seem that in a calling so high, so noble, so sacred, men fit for such ministry should be sought for; but the great question of the young graduate is not 'Who wants me?' but 'Who will employ me?' not 'Who needs me?' but 'Where can I get a living?' In the case of four physicians dying, each in a country village, during the last year, I am credibly informed that in one instance two, in another three, in the third five, and in the fourth case seven new men came to look the field over within ten days after the doctor's death, sometimes before the burial. In

one case ten attended the funeral, and in another the widow had three letters from aspirants for the vacant place while the dead body of her husband still lay in the house.

"It is a hackneyed saying, with which too many ears are tickled, that 'there is always room for good men.' Applied to the present condition of our profession, it is false. Were only good men and the best men admitted, it would undoubtedly be true. But all over the land, in city and country, are well-educated, cultured gentlemen, honest and loyal, striving in vain to secure a competence—yes, a bare living even—and too often is disappointment mingled with shame and mortification at the success of ignorant and unprincipled rivals. I have said that the evil results of this excess in numbers are manifold. It leads to over-practice and to bad practice. The man who is hard pushed, who has few patients, and needs more, is tempted to make much of little; to magnify the importance of his cases, both in his own mind and to his patrons; to make uncalled-for visits, and to give too much medicine; and unnecessary medication soon ceases to be rational. Patients are injured in mind and body. The community is injured by teaching the people to attach undue importance to trivial diseases, and to over-estimate the value of treatment therein. Legitimate, honest practice suffers in reputation; money is obtained under false pretences."

Arkansas State Medical Society.

The Eighth Annual Session will be held at Little Rock, on Wednesday, May 30, and Thursday, May 31, 1883, commencing on Wednesday at 10 a. m.

Each county or municipal society shall be entitled to one delegate for every five members, and one for a fraction over five.

The subjoined are the committees to report at the next meeting:

Committee on Medical Education: T. W. Hurley, Chairman; W. B. Welch, W. A. C. Sayle, W. H. Hawkins, W. H. Hardison, D. C. Ewing, D. H. Dungan.

Committee on Practice of Medicine: J. A. Dibrell, Sr., Chairman; D. H. Dungan, T. D. Nichols, Z. Orto, G. W. Hudson, A. N. Carrigan, G. M. D. Cantrell, P. H. West, J. F. Simmons.

Committee on Surgery: J. A. Dibrell, Jr., Chairman; J. R. Dale, C. L. Kirksey, Wm. B. Lawrence, J. E. Bennett, J. M. Keller, W. B. Welch.

Committee on Gynecology: Edward Cross, Chairman; R. N. Ross, W. H. Heard, J. F. Blackburn, D. S. Williams.

Committee on Medical Legislation: R. G. Jennings, Chairman; G. B. Malone, A. A. Horner, C. Watkins, P. Van Patten, W. W. Hipolite, A. B. Loving.

Committee on Necrology: A. N. Carrigan, Chairman; R. B. Gladden, J. T. Jells, J. F. Blackburn, G. S. Brown, E. H. Alexander, R. C. Wallis.

Board of Visitors to the Medical Department of the Arkansas Industrial University: Isaac Folsom, Chairman; J. E. Bennett, W. W. Hipolite, W. H. Hawkins, Z. Orto.

Committee on State Medicine: Z. Orto, Chairman. Secretaries of local societies are requested to forward, as soon as appointed, a list of the dele-

gates, together with a complete roster of officers and members of their respective societies.

Arrangements will be made by which reduced rates can be obtained by all who may attend the meeting.

Little Rock, Ark.

L. P. GIBSON, M. D.

Secretary.

Ohio Health Legislation.

The following bill was recently passed by the legislature of Ohio to amend section 2135 of the revised statutes of Ohio:

Sec. 1. Be it enacted by the General Assembly of the State of Ohio, that Sec. 2135 of the revised statutes of Ohio be so amended as to read as follows:

Sec. 2135. The Board of Health may take measures and supply agents, and afford inducements and facilities, for gratuitous vaccination and disinfection; may afford medical relief to and among the poor of the corporation, as in its opinion, the protection of the public health may require; and during the prevalence of any epidemic, may provide temporary hospitals for such purposes; and the said Board is hereby required to inspect semi-annually, and oftener if in the judgment of the Board it shall be deemed necessary, the sanitary condition of all schools and school buildings within the limits of the corporation.

Sec. 2. That the said Sec. 2135 be, and the same is hereby repealed.

Sec. 3. This act shall take effect and be in force from and after its passage.

Investigation of Cattle Diseases.

Commissioner Loring has decided to institute a series of investigations into the diseases of cattle, and for this purpose has designated Dr. D. E. Salmond, who has for years been connected with the Department of Agriculture. Experiments in inoculation, etc., will be made. The Pasteur system, and such modifications of it as have suggested themselves to Dr. Salmon, will be used. The investigation will be conducted with a special view of ascertaining the nature, and the means of prevention and cure of Texas cattle fever, pleuropneumonia, and hog and chicken cholera. The results of the researches already made by Dr. Salmond are such as to make him feel reasonably confident that he will eventually be able to discover remedies which will enable any farmer to prevent or cure the diseases mentioned.

State Board of Health of Wisconsin.

The State Board of Health of Wisconsin calls the attention of all town boards, village boards, and common councils of cities in Wisconsin, to the provisions of Chapter 167, of the laws of 1883.

This law makes obligatory—

1. The organization of a Board of Health in every town, village and city in the State, within thirty days after each annual election.

2. The appointment of a Health Officer by every Board of Health, within ten days after its organization.

3. The report of contagious diseases by all physicians.

The French Method of Collecting Statistics of Contagious Diseases.

In order to obtain daily statistics of the occurrence of contagious diseases in Paris, the Préfet of the Seine has distributed to all the medical practitioners of the city books of cards with counterfoils, on which are printed forms, leaving a few blanks to be filled up announcing the locality, the nature of the disease, where and how it was contracted, and so on. These cards as they are filled up are to be dropped into the post, and will be forwarded to the central bureau, where the statistics thus obtained will be classified day by day.

Leeches.

The *Chemist and Druggist*, March 15, 1883, says the plan that seems most uniformly successful in keeping leeches is to place them in a vessel of water about half full, with about half a dozen rough stones the size of oranges, changing the water about once in six months. If the sides of the vessel get covered with vegetation, clean them down with the water, but do not change it. If a leech dies and taints the water, it must be changed. As a rule, it has merely a fishy odor. Some prefer to grow water-plants, such as *Anacharis* or *Vallisneria*, in the vessel.

Items.

—On November 15, 1882, a polyclinic was opened in Rio de Janeiro, under the direction of Dr. Moncorvo.

—Governor Cleveland, of New York, has signed the bill prohibiting the manufacture of cigars in tenement houses in New York city.

—Judge Landen, of New York, recently ruled "that if a prescription of a regular practicing physician is put up as written, the druggist is not responsible."

—The Medical Department of the State University of Iowa will insist in future that all applicants for admission must pass a preliminary examination in the English branches.

—The Châteauevillard prize of the Paris Faculty of Medicine has been divided between Dr. Giraud Teulon for a work entitled "Vision and its Anomalies," and Dr. Cadial, for a "Treatise on General Anatomy."

—According to the statistical report of the State Board of Health, there were 25,942 deaths in New Jersey in 1882, an increase of 5,000 over the previous year. There were 8,837 marriages and 23,108 births.

The stiffest-necked boy in Schuylkill county lives in Pottsville. He fell off a farm sleigh and the runner passed over his neck. When a crowd from the corner store ran to pick up the supposed corpse, the boy scrambled to his feet and ran after the sleigh.

OBITUARY NOTICES.

J. C. DUNDAS, M. D.

Dr. J. C. Dundas, of Cambridge, Dane county, Wis., died of pneumonia April 17th. He was born in Norway in 1815, and after receiving a thorough medical education and traveling ex-

tensively, finally settled down in Cambridge, Wisconsin.

He was an intimate friend of Henrik Wergeland, the Norwegian poet, and also of Ole Bull, and J. L. Runeberg, the Finnish poet.

The doctor was himself a poet of no mean ability. He has contributed many poems to the Scandinavian press, and had intended soon to publish a volume of poems.

MEDICAL DIRECTOR J. C. PALMER.

Medical Director James C. Palmer, on the retired list of the navy, died in Washington, April 24, 1883. He had seen thirty-eight years of active duty in the navy, and had sailed all over the globe. He was a native of Maryland, and received his appointment from that State on March 26, 1834, entering the service as an Assistant Surgeon. He was attached soon after to the frigate *Brandywine* of the Pacific squadron. In 1836 he made the trip around the world in the schooner *Vincennes*, and afterward was connected with an exploring expedition from 1838 to 1842. He received his commission as surgeon in October, 1841, and served in the Home and Pacific squadrons until 1856. He was then ordered to the frigate *Niagara*, accompanying that ship in the cable expedition of 1857. After a short service at the Naval Academy at Annapolis, he was made Fleet Surgeon of the West Gulf squadron during the earlier part of the war, with his headquarters on the flag-ship *Hartford*, and was present at the battle of Mobile Bay, August 5, 1864. In 1866 he was ordered to the Naval Hospital in this city, and from thence was delegated to special duty at Newport until 1872, when he received the appointment of Chief of the Bureau of Medicine and Surgery. This office he filled for a year, and retired from active duty in 1873.

QUERIES AND REPLIES.

B. C. R. "DAY ON HEADACHES" is a very good book.

MARRIAGES.

HALBERSTADT—MOORE.—On Thursday evening, April 26, 1883, at St. Luke's Church, Germantown, Pa., by Rev. W. Maule, LL. D., assisted by Rev. W. Lewis, D. D., Dr. George H. Halberstadt, of Pottsville, Pa., and Edith, daughter of the late Dr. Thomas Moore, of Germantown.

LAFFERTY—TOWNSEND.—On April 10, 1883, by Rev. A. Donaldson, D. D., J. H. Lafferty, M. D., of New Florence, Westmoreland county, and Miss Anna M. Townsend, of Maysville, Armstrong county, Pa.

MARSH—ATTRIDGE.—On April 9, 1883, in Keene, N. H., by C. Fred Webster, Esq., Dr. David Marsh and Mrs. Catharine Attridge.

PUTNEY—YOUNG.—On April 17, 1883, at the residence of the bride's parents, Brooklyn, E. D., by Rev. Dr. Eddy, Helene S., daughter of Dr. John Young, and Dr. Willis S. Putney, of Bethel, Conn., son of Rev. R. C. Putney, of the New York East Conference.

DEATHS.

ROSENCRANTZ.—In this city, on Sunday, April 22, Dr. John Rosencrantz, in the 74th year of his age.

SHARPLESS.—In this city, on Sunday, April 22, Dr. John T. Sharpless, in the 83d year of his age.

WEBB.—In this city, on Tuesday, April 24, James P. Webb, M. D., in the 84th year of his age.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

PRESIDENTIAL ADDRESS DELIVERED AT THE MEETING OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

BY WM. VARIAN, M. D.,
Of Titusville.

GENTLEMEN: Thirty-five years ago there met in the city of Lancaster a small and earnest body of medical men, who organized "The Medical Society of the State of Pennsylvania," and announced as their object "the advancement of medical knowledge; the elevation of professional character; the protection of the professional interests of its members; the extension of the bounds of medical science, and the promotion of all measures adapted to the relief of suffering, the improvement of the health, and the protection of the lives of the community."

More than a generation of human beings have accomplished their earthly pilgrimage since that meeting was held. Yet still it is our privilege to see in the audience here assembled more than one of the original founders of this Society, who, in the year 1848, were present at its organization.

These men have worked for full thirty-five years to advance the noble object of their incorporation. They have encountered much discouragement in their enterprise, and have overcome many obstacles in the opposition incurred from the misapprehension of motives, or the conflicting of selfish interests which have arisen from without, as well as in the friction necessarily developed within the Society itself. God grant, that for many years to

come, the few who still survive that small body of pioneers, may be privileged to meet with the hundreds who now throng to the annual meeting of this Society, and, while watching with pride the result of their work, be annually greeted by us with loving reverence, as we profit by their counsel and ripened experience.

And what do these, our fathers, see as the result of the generation's work to which they have devoted themselves?

Instead of the half dozen counties in which societies were organized at the time of their first assembly, they now behold an active, living county society in almost every one of the sixty-six counties in the State.

In lieu of the few members, who could then easily be counted by tens, and but few of *them*, nearly eighteen hundred physicians are now enrolled upon the list of members; and the meetings are thronged by hundreds of the best men and women in the State, who yearly assemble to read and discuss papers on every branch of medical science and State medicine. Here they come to sift each others brains and garner for themselves the medical wheat which has been grown in every corner of this great Commonwealth. Here, too, they grind and bolt this grain which, made into bread, furnishes food to every medical mind of the eighteen hundred members of this truly great "Medical Society of the State of Pennsylvania." Our fathers see this Society always keeping in prominent view the last clause of that great object with which it was founded, and yearly becoming a greater power in influencing legislation for the establishing of hospitals for the insane, the feeble-minded, the sick, and the af-

flicted. Never ceasing their efforts to obtain wise and efficient legislation in behalf of State hygiene; educating themselves, and those about them, in the true method of preventing disease; how best to build, to drain, to ventilate, and to heat their public buildings and their dwellings; how to properly clothe and feed their children and themselves; how to avoid the dangers of contagious diseases and to strangle or stamp them out when they arise; all this, and much more, do these, our fathers, behold as the result of their small beginning, and can now grasp each others' hands in hearty congratulation on seeing their work pushed forward by clear brains, strong hands, and willing hearts, and feeling that it will never cease so long as human weakness and human blindness continue to outrage nature's laws, and thus make medical science necessary to their physical salvation.

Fellow-Laborers in the Science of Healing! We have still a great burden of work to accomplish.

Charlatanry, superstition and ignorance still roam almost unchecked throughout our state, and are ravaging upon the spoils to be gathered from those whose bodily afflictions render them credulous of the vaunting assertions of Empiricism. And as yet, there is no, or at least insufficient, legal protection for our wards.

People of all sorts and conditions of life, in town and in country, daily sin against the laws of health, originating and disseminating the seeds of disease which endanger themselves, their neighbors, and even the entire community in which they live; and as yet there is no State Board of Hygiene, which would render it possible to invite them to the marriage-feast of health and pure living, and compel them to come in. We need, and we must have, a State Board of Health, strengthened and supported by local boards in every city, town, and borough; that we may be enabled to carry out our object to promote the well being of our fellow-citizens. The great aim and object of our being, as physicians, is to prevent disease. Our duties as healers of the sick are but secondary. In order that this aim can be accomplished we need a body endowed with legal powers to enforce sanitary laws in all public and private enterprises. In the construction of our school buildings, our churches and our hotels; in the regulation of public funerals; in the drainage and water supply of our towns; in the arrest of the spread of contagious diseases; in the supervision of vaccine farms; in every particular in which the public health requires protection; these sanitary laws should be enforced, and this State

Board of Hygiene should be empowered to enforce them. Let us then continue to wage the conflict with ignorance, selfishness and indolence. No matter how frequently repulsed, let us never be disheartened. Every time we are thrown to the earth let us rise with renewed vigor and return to the conflict, until we have succeeded in our object, and have at our command the means to prevent the preventible diseases to which man is subject, within the limits to which human knowledge permits us to go.

Among the hygienic problems of the future whose claims we can now see looming upon the horizon, and whose demands for solution become more imperative as time passes away, none is of more importance than the disposition of the dead. The steady increase in the presence of zymotic diseases, and their widespread and almost universal diffusion wherever civilized man inhabits the earth, is a subject of grave thought and serious alarm. However much scientists may differ as to the entity of the germ or the malaria which constitutes the primary poison of diphtheria, scarlatina, typhoid fever, and other systemic diseases, they are all agreed in looking for the sources of this poison in the water that we drink and the air that we breathe, contaminated, as they are, by the gaseous, fluid, or solid results of the decomposition of animal and vegetable debris. Whether these destructive influences are the product of telluric operations of a mysterious character, or of subtle changes in the chemical laboratory of nature which we are not yet able to explain, or to the germination of microscopic beings, whether animal or vegetable, which find their nidus and habitat in the hot-bed of decomposing matter, and when transplanted to the vital tissues, exercise a destructive influence, we will not now stop to inquire. But it is not too soon for us to begin to consider whether self-protection does not demand of us that we should abstain, so far as lies in our power, from adding to the constantly accumulating mass of animal debris which is steadily supplying nature's magazine with an increasing amount of material for the manufacture of these lethal influences. Is it not time that a sentiment hitherto fostered by a long continued but dangerous custom, should yield to practical scientific common sense, and that we should take measures to prevent future generations from being obliged to inhale or swallow the exuvia of the charnel-house or the grave, and so lessen for them the evils to which we are exposed? It ought to be very easy for us to solve this problem, since the solution is given in the single word *cremation*.

Let all refuse animal matter, whether human remains or those of the lower animals, be promptly condemned to the ordeal of fire, and we will be doing a great deal to lessen the dangers and ills of the human race. Let the Crematory take the place of the Cemetery, and we will in some degree protect our children's children from being obliged to suffer the loathsome and deadly diseases which in this age afflict ourselves. Nor, on due consideration, ought this suggestion to shock the sentiment of the most refined and delicate mind? Think! To what does sepulture condemn these mortal shells we call our bodies? To a slow and gradual resolution into their elements of gases and earthy matter. And while this process of resolution is going on, requiring, as in many instances it does, years of time, the foul decomposing mass is but a putrid abomination to all humanity, a festal hall for the most loathsome forms of created beings, a source of horror and disgust to the minds and thoughts of loving friends and relatives. But expose this same semblance of mortality to the purifying chemistry of the crematory, and in a few short minutes you have accomplished the work which has required months by the slow process of nature. The same resolution of animal matter into the elements has taken place, but not in the same protracted manner, and unaccompanied by the same disgusting surroundings, and without danger of producing the same destructive and lethal results. "Dust thou art, and unto dust shalt thou return," would then be made a rapid and literal fulfilment, instead, as now, a partial carrying out of the Divine decree. Our cemeteries would then be lovely and healthful pleasure grounds, where the contemplation of the last resting-places of our beloved dead would be indulged in without danger, and free from the shuddering consciousness of the horrors of decay adding its harrowing and loathsome reminders to our grief. Public funerals would cease to be the media of the spread of contagious disease. And when the cinerary takes the place of the coffin, the most sensitive and affectionate of human beings can calmly contemplate the last resting-place of mortality without danger and without disgust. Let it be our mission to educate the opinions of both ourselves and the public towards this disposition of all animal remains as a measure both of public hygiene and of æsthetic fitness.

Within the domain of State Medicine, and belonging specially to the department of those who make a study of mental and nervous diseases, there still remains a form of disease which has too long received insufficient attention, and whose

claims I wish to urge upon you in a few brief remarks.

As a question of political economy, and because of its effects upon the social fabric of society, none of the problems of civilization have aroused greater interest, have demanded more thoughtful consideration, have excited the passions and fanaticism as well as the earnest prayerful enthusiasm of mankind, to a greater degree, than the abuse of alcohol in all its kaleidoscopic forms. How to use it, and how not to abuse it, are questions in the answering of which as individuals and as citizens we must necessarily take a more or less degree of interest, in proportion to the sense of duty towards our fellow-man which actuates us, or the keenness of perception of its importance to the State, the community, and the family, with which we are gifted. But it is not my intention to dilate upon this aspect of the question, as this is not the time or the place for its consideration, or for a dissertation upon the civil, social, and personal effects of alcohol. Neither, if it were, would I have the inclination to write, or you the patience to listen to, any such discourse. But there is a problem connected with the subject which has a purely medical aspect, and which belongs to us as a professed body of healers of the sick, to endeavor to solve. By its solution we will do not a little to lessen the difficulties which stand in the way of our legislators and reformers, to reduce the number of criminals and paupers, and tend to reduce the number of inmates in our county houses, jails, and insane asylums.

The question is, what can we do to restore the inebriate to a condition of moral, mental, and physical health? Let us successfully answer this question, and we at once reduce crime from sixty to eighty per cent., largely diminish the expenses of the commonwealth, add immensely to the wealth of our State, and greatly reduce the death-rate consequent on diseases of the liver, stomach, kidneys, lungs, and brain. And this I look upon as purely a medical question. Upon us as medical men rests the responsibility of satisfactorily answering it. Shall it be said that we are, and always will be, unequal to the task? In view of the stupendous benefits to be obtained, are we just to ourselves and to others if we longer delay in fairly grappling with the difficulties, and by care and study overcoming them? Although we have ever been fearless in the pursuits of our art, eager to grapple with the mysteries of pestilence and disease, pursuing our investigations regardless of personal risk, alike through the slums of the city, the purlieus of the camp, and the pesti-

lential holds of the ship, we seem to have relegated this disease to the care of the political economist, the poor-law commissioner, or the civic judge.

We are all familiar with the result of treating the inebriate as a felon—thrusting him into the work-house or the jail for a few weeks or months, and then sending him out with enfeebled mind and body to encounter the temptation of his appetite, without having obtained any physical or mental strength to resist its depraved instincts. The frequent repetition of this course soon produces a real criminal, or else ends in a pauper's grave, or an insane asylum. We have also seen the effects of expending large sums of money in the maintaining of elegant asylums, which will serve as delightful retreats within whose pleasant and even luxurious retirement the inebriate can recover from the effects of a season's indulgence, and from which he issues after a period of enforced abstinence, with his physical energies recruited, but with moral and mental faculties still enfeebled, only to resume his evil habits after a brief interval of reason. Neither the penitentiary, nor the asylum—the one a representative of physical force, the other of moral suasion—has as yet proved effective. Yet, perhaps, it will be to the latter, in its proper development, that we must turn to accomplish our end. What is the medical problem which we have to encounter? Given: A man diseased in mind and body, with his nervous system debilitated and deranged, and his physical organs changed and disordered; how can we cure him? The investigations and careful studies of Dr. Crothers, of Hartford, would seem to throw light upon the direction in which we should begin our efforts, and I would suggest the careful study of his thoughtful papers on this subject to those who have not already perused them. My own aim is not to elaborate a plan of treatment, but simply to suggest the subject as one worthy of the attention of those able and experienced men who make mental diseases a study, who, when their attention is once elicited, will doubtless soon demonstrate a practicable course of treatment for the accomplishment of so important a purpose. Since our efforts during the past fifty years have resulted in such remarkable benefit to the insane, the feeble-minded, and other wards of the people, let us study to accomplish as much in the near future for the equally unfortunate and irresponsible victims of alcohol.

Among the boons which the science of medicine has conferred upon the human race, none has proved greater, or has better endured the critical

tests of time and experience than the prophylactic power of vaccination. Yet even here the fashion of the day has made its changes; the experience of years has been overslaughed by the desire for novelty, and the well-proved powers of humanized virus have been buried, and almost forgotten, under the plausible theories and loud assertions of the advocates of exclusive animal vaccination. During the past ten years humanized virus has been nearly driven out of use, and, in spite of generations of experience, has been almost entirely supplanted by the presumably purer and more potent animal virus. But unless greater care is exercised in the production and preservation of this favorite virus, and intelligent inspection and jurisdiction is exercised over all vaccine farms, the time is not far distant when the advocates of exclusive animal vaccination will see their "vaccine boom" share the fate of the numerous plausible theories which have had a brief existence, but have failed to endure the crucial test of long-continued and careful trial by the profession. A brief recital of my personal experience with animal vaccination, although doubtless identical with that of most, if not all, here present, will not be out of place, and will serve to explain my remarks on this subject. Although entirely satisfied with the purity and efficiency of humanized virus as cultivated and carefully selected by myself, I had, during the past ten years, at first partially, and then entirely, abandoned its use; yielding my experience and convictions in part to the theoretical purity and efficiency of animal virus, and in part to the fashionable outcry for its employment. The uncertainty of the action of animal virus, and the frequently recurring necessity for its renewal, I found wearisome and discouraging. The brief period which elapsed after a successful vaccination before the subject became susceptible to a re-vaccination argued a weak prophylactic power, which argument was not weakened by the occasional occurrence of varioloid shortly after a successful vaccination. But I still persevered, for I felt it my duty to give my patients what was considered the purest and best means of prophylaxis that could be obtained. Still I could not but feel that the entire failure of at least thirty per cent. of all my primary vaccinations was discouraging, and the necessity of going over the same ground again and again was, to speak mildly, monotonous. During the winter of 1881 and 1882, small-pox was epidemic, and its loathsome wave rolled over the entire country. Almost every individual in my section demanded

vaccination, and it was necessary to obtain material from every source of supply within my reach. The result in many cases was the production of an unhealthy and poisonous sore, often plagadænic, and always inflammatory, which gave great trouble and frequently took weeks to heal. These cases all suffered from severe systemic disturbance, which in some cases was not without danger to life. When finally healed, the cicatrix in some cases became the seat of an erectile tumor which resisted all measures of destruction, and was finally removed by extirpation with the knife. Had this experience been personal to myself alone, it would have proved disastrous to my practice and reputation; but it was a common experience to all practitioners in my neighborhood; and the universality of the misfortune was our protection from public reprobation. An experience of nearly thirty years use of humanized virus had shown me that it possessed great protective power against variola, together with certainty of action, and freedom from any such effects as above described. Less than ten years' use of animal virus has led me to believe that it is uncertain in its action, that its protective power is not so lasting, and that at times it was not free from a liability to produce disastrous effects. I have strong doubts whether any protection from variola has been obtained in those cases wherein the inflammatory sore above described was produced; but I have no doubt whatever, that it would now be difficult, if not impossible, to induce the sufferers to submit themselves to another vaccination. So far as I have collected the testimony of the medical men in my vicinity, their experience has been similar to my own, and their faith in animal virus has received a rude shock. I repeat, then, my assertion as to the necessity of expert inspection and control of the sources of animal vaccinia, as a necessary feature of State medicine, and as a protection against the possibility of diseases scarcely less to be dreaded than small-pox itself.

The subject of medical education has been so often discussed before you, that were I to occupy your time with an elaborate presentation of its necessities, I would, I fear, only weary you by a repetition of remarks with which you are already familiar. The importance of a firm foundation being first laid in the preliminary education of the student is recognized by all; and the best means of effecting this, and the standard which shall be required of all who essay in the future to enter the profession, is a subject of consideration and action by you at this session. I have no doubt

that you will arrive at a conclusion both wise and practicable. I simply allude to the subject with a view to making a single suggestion. It is that the importance of establishing a chair of State Medicine and Hygiene be urged upon all our medical schools; that attendance upon the lectures on this subject be made obligatory; and a satisfactory examination thereon be made one of the requisites of graduation. If we use the influence of this Society for the accomplishment of this advance in medical education, we will do not a little to raise the status of the medical man to a higher grade, as well as to greatly increase his usefulness. If in addition to this we can influence all of our medical schools to insist upon not less than three full years of attendance upon medical lectures before a diploma will be granted, we shall have taken a long step forward on the path of improvement in medical education.

The dilatory appearance of the Transactions of the Society in a published form is a subject of great complaint, and it behooves us to see whether some measures cannot be taken to obviate this in the future. Frequent allusion has been made to this subject, and that it is a serious evil is universally acknowledged; but as yet no successful steps have been taken to seek out a better or speedier way of bringing the valuable papers yearly read before this Society into the hands of its members. Many a practical suggestion which seems to meet a daily or frequently recurring want in the practice of some individual member, can be but imperfectly recorded upon the tablets of memory whilst listening to the rapid reading of a paper, and when required for use the recollection of it has become so blurred and vague as to be of little value. Month after month passes whilst anxiously awaiting the appearance of the Transactions, so that he can read and digest at his leisure the numerous valuable papers to which he had listened in such rapid succession that their impressions were blended upon his mind in one panoramic picture, the individual features of which he is unable to fix and retain. But he waits in vain. The impressions received grow dim. The interest excited on special points of importance in his own practice passes away. And when finally he receives a copy of the Transactions just as he is arranging his business, and his linen, to again take his seat in the State Society, his interest in it has vanished, and he lays the work upon his table with regret that its usefulness to him has, in part, gone by. Is there no remedy for all this? Which one of you gentlemen would submit to such delay in the publica-

tion of a work of this size, were it the creature of your own brain and handiwork? What publisher would dream of protracting the issue of so small a volume beyond a period of sixty or ninety days, were *you* or *I*, as individuals, its author, and interested in its publication? Why then should the 1800 members of this Society be obliged to suffer from such delay? But if it is said, and *proved*, that as now published this delay is unavoidable, and arises from sources outside of the printing-house, then we should inquire some better and prompter way of distributing among the members the numerous valuable and practical essays which render our sessions so interesting. One way might possibly be to reduce the number of the committee on publication to one active member, and paying him a suitable compensation for his work, proportioned to the promptness with which it is executed. Another method would perhaps be to learn a lesson from the course about to be undertaken by the National Medical Association. I do not mean that this Society could advantageously establish a journal of its own, nor do I believe any such course necessary. But I think it not impossible that an arrangement could be made with one of the already well-established weekly journals of the State, which would prove of advantage both to the Society and to the Journal. I am informed that the expense of publishing our Transactions in their present form is about \$1600. The payment of but little more than half this sum, together with granting the exclusive privilege of publishing the valuable papers which are read before the Society, would probably be a sufficient inducement to one of our medical journals to lead them to to furnish a copy of their journal either free or at a greatly reduced rate. Increase of circulation and of advertising facilities, together with a liberal supply of the best of material for their journal, would result to the advantage of the journal. The early access in print to papers of personal interest, and a weekly journal at a cheap rate, would redound to the advantage of the members of the Society. Our Minutes could then be published by the Society in a small and inexpensive pamphlet, over the production of which the publishing committee would be allowed to spend 364 of the 365 days which elapse between our sessions, and never hear a whisper of complaint. Neither of the measures here suggested may in your judgment be suitable; but if my remarks shall have any influence in causing you to evolve a feasible means of removing this source of complaint, they will have fulfilled their end.

The action of the medical society of a neighbor-

ing State in throwing down the barriers which have been so long maintained between the science of medicine and legalized dogmatism, received from you at your last session an expression of unanimous disapproval. The renewal of this action by the same Society, together with their refusal to appoint delegates to the National Association, and thus practically seceding from its fellowship, demands that you should again express your reprobation at their persistence in wrong-doing, in language that cannot be misunderstood.

Action which has met with remonstrance, and unqualified disapproval, from every other medical society, cannot but result in placing that society in a position of antagonism to the opinion of the entire medical world. Let us speak then in no uncertain tone of voice when we express our condemnation of action which arrogates to a subordinate body powers which belong only to the highest associated medical authority in our land, and which renews in a medical form a conflict which, in its political aspect—within the memory of every person here present—deluged our land with blood and exhausted the treasures of our country. I wish here to record my personal protest against that action, as being *unnecessary, unjustifiable, and revolutionary*.

And now permit me to pause and say a few words to that portion of this audience who do not belong to the profession, but who have been attracted here to-night either by interest in the progress of science, or by curiosity to ascertain the reason for the assembling of so large a number of the best medical men in the State.

If you have listened with patience to the few remarks that I have made, you have learned that, in the main, our object is to consult together and to devise the best measures that science and thought can contrive, to protect you from the onslaught of disease, and to relieve you from its effects when you are attacked. In this battle of ours, which must be waged so long as "human flesh is subject to human ill," you cannot stand by as idle spectators calmly awaiting the result. Your own interests and those of your loved ones are too intimately blended with our aims, to make it safe for you to show any indifference or indecision in action, when such a vital conflict is in progress. Permit me then briefly to show you how you can aid in promoting the noble aims and objects of this Society, and become co-laborers with us in this conflict with disease.

And first, let me request your aid in the proper education of physicians, so that they may be

thoroughly fitted for the work that lies before them. How can you render efficient help in this direction? I answer: by forbidding and discouraging your sons, brothers, and acquaintances from commencing the study of medicine before they have undergone such careful preliminary education in classics and the natural sciences, as will fit them to understand and fully master the intricacies of the art and science which they expect to make their life-long work. Urge upon them that they become well grounded not only in the elements of a good common school education, but also in mathematics and the natural sciences; and that they also obtain a familiar knowledge of Latin and Greek, and if possible, of the modern languages. All of these studies are but a necessary preparation to the proper study of medicine; and without the preparation of mind by this preliminary education, the student is obliged to accept as dicta of his teachers, by faith alone, much that is beyond his comprehension, and which, being the ground-work of all scientific thought and research, should already be familiar to him. Without this he will be forced to go through life handicapped by a lack of education which prevents his mastering his profession, and renders him unworthy of the full trust and confidence of his patients, because ill-fitted to do his duty by them. With as much propriety could you send a soldier into the heat of battle without cartridges, as a student to a medical college without the broad intelligence and trained habits of thought only to be obtained by a broad academic, and if possible, collegiate education. In the one case you expose the soldier to almost certain destruction; in the other you expose yourself to equal danger from the mistakes of a half-educated physician.

With your sons thus properly prepared to enter upon the study of medicine, encourage them to seek for a mastery of that profession which should honor those who enter it, and be honored by every one of you who are so dependent upon it. To this end discourage in them all desire for the hasty obtaining of a diploma, as a license to attach to their name the empty title of doctor, and be privileged by the mystical letters M. D. to feel a pulse and look at a tongue, before they know the true interpretation of the varied beat of the one, or have learned to translate the language of the other. The day has gone when by the graduate of a medical school, which turns loose upon the world a half-educated licentiate, who has spent a few months in a confused attempt to understand a couple of scanty courses of lectures, can take

rank with the alumni of those schools which demand three and more years of the closest application from their students; and encourage them if possible to devote, at least, two additional years to the study of their profession ere they launch themselves upon the rough sea of professional life. Demand as your right the highest possible education for the physician of this day; and enforce your demand by refusing to entrust your health and your persons in the hands of the uneducated; and by sending your student sons and brothers to those schools only which afford every facility to obtain a complete education, and which exact of their graduates a complete mastery of the course prescribed.

Again, you can assist in the great aim and object of our work by using all your influence, whether social or political, in favor of all legislation which has for its aim the arrest of the spread of contagious diseases; the purification of the sources of water supply; the abatement of nuisances prejudicial to health; the sanitary inspection and control of school-houses and buildings of public accommodation and resort; and the care and cure of those who, by misfortune or disease, have become incapable of self-protection, and so are wards of the people. By so doing you will be helping and protecting yourselves, as well as us. As individuals, our pecuniary interests conflict with the arrest of the spread of disease. But our moral duties, as physicians, demand that every measure within our reach shall be employed by us which tends to promote the health and well being of our fellow-men. We ask of you, then, to insist upon the passage of all well-devised laws which have this end and object in view. Since no political end can be obtained by the passage of such laws, we are constantly opposed and defeated by the legislators of the State, who raise the empty outcry of "war among the 'pathies'" as an excuse to refuse legislation whose sole object is to promote the welfare of the citizens of this Commonwealth. If you will arise to a sense of the importance of such legislation to yourselves and your families, and will bring to our aid all the force of your political, social, and personal influence in demanding such legislation as yours by the divine right of necessity, these laws will be promptly passed; and you will reap your reward in the assured health of your families, and the happiness which is health's sure accompaniment.

Again: Should there happen to be in this audience any persons who, being largely endowed with this world's wealth, are desirous of being

almoners of God's bounty to them, and of promoting the welfare of their fellow creatures by facilitating and cheapening the means of education to our noble profession, it would be the part of wisdom if they were to use such portion of their wealth in endowing chairs in some medical school which has already achieved a well established and deserved reputation, and thus enlarge its usefulness, and lessen the expense of a generous medical education. A few hundred thousands thus bestowed to enlarge the usefulness of such reputable schools of medicine as pertain to the University of Pennsylvania, or to Jefferson College, would be of more widespread benefit than ten times the amount devoted to the establishment of a new college, the necessity of which is only apparent to the mind of the founder, while it would prove to be an equally glorious memorial of the benefactor.

It would be easy for me to add many more hints to the few that I have here outlined, attention to which will make you valuable assistants to us in our efforts of general beneficence, and will return to you in an increase of health and the duration of life, and thus restore fourfold to your bosoms.

Fellow members, in this large gathering of physicians who greet me to-night, it gratifies me to recognize so many individuals, members of each of the two classes of doctors whose labors redound in such honor to our profession.

In the one class are those whose natural bent of mind induces them to pursue the path of minute investigation and research, and with the assistance of the various instruments of precision, chemical analysis, and the numerous measures of physiological and philosophical investigation, carefully search out the secrets of nature, and endeavor to wrest from them the primary cause of sickness and disease. The glorious results of their labors prove beyond a cavil the falsity of the assertion that medicine is not a science. If this were ever true, it certainly is not true in this, our day. A shrewder, more skillful, and more indefatigable body of trained scientists than those who are working in the medical ranks to-day, and so many of whom I see before me to-night, cannot be found in the ranks of any other profession. Full of eager enthusiasm and care-taking determination, they are investigating every branch of their profession, seeking for the primary cause of, and the remedy for, every disease which tends to shorten life. Although sometimes misled when apparently on the right path, there is no discouragement and no retrograding in the general advance. Each one advancing clears some ground

for him who follows, and the aggregate of progress constantly adds to the glory of the profession, as well as to the welfare and comfort of man.

To the other class belong those practitioners of medicine, who, starting from the same goal with the first, prefer to devote their lives to the pursuit of their art instead of the science of the profession. These men are the true healers of the sick, who carefully and industriously study the signs of disease and the methods of its cure. By carefully investigating the physical aspects of disease, and studying the effect of the therapeutic means within their reach, they are enabled to store up and record an amount of practical knowledge that at times seems in its insight to be marvellous, and is really that true and only genius which is the result of labor, observation, and thought. These men test and weigh the discoveries of others, and assign them their practical value in the prevention, the amelioration, or the arrest of disease. Possessed of bold and fearless yet cautious minds, trained to self-reliance and judgment by many a single-handed conflict with the many-sided phases of disease, they accept no person's dictum as law, but welcome every plausible suggestion or theory, and weigh, study, observe, and experiment with it until they are prepared to accept and adopt it as a well-proved truth, or reject it as unable to endure the crucial test of practical application.

These two classes of medical men are necessary corollaries of each other. Each is alike an essential element to the progress of our science and art. And although medical thought, as exemplified in the current literature, will naturally vacillate first in one direction and then in the other, true progress is only found in the steady advance of each, side by side and shoulder to shoulder. At the present moment, the advance of the scientific investigator is perhaps the most rapid. Outside of the surgical branch of our profession, which is making such wonderful progress, the microscopist, the chemist, and the physiologist are probably making the most marked impression upon the medical thought of the age. These men are accumulating material with such rapidity that the others can scarcely sift and test it. But the equilibrium will not be long displaced; and meanwhile let it be our aim, each in his own chosen field, to so do his individual part to advance and sustain the noble science of medicine, that those who come after us will look upon our work with gratitude and reverence, as that of men who did their duty to their profession, and who lightened the labors and the cares of their successors.

ADDRESS IN OBSTETRICS,

Read before the Medical Society of the State of Pennsylvania.

BY GEO. O. MOODY, A. M., M. D.,
Of Titusville, Pa.

If there is any position within the limits of our profession, where the physician should be held rigidly responsible for neglect or incompetency, it is when he stands at the bedside of a woman in the perils of child-birth. He should never be allowed by law or custom to assume the responsibilities of this position until perfectly prepared, promptly and intelligently, to meet every emergency which, without a moment's warning, an attendant in such cases may be called upon to face, with the ever-present conviction that any mistake or indecision on his part may cost a human life, or doom his patient to months, and perhaps years, of helplessness and suffering, with little hope of relief, and too often with little encouragement or sympathy. To give back to her family the wife and mother escaped from these perils is the highest office of the physician, and one to which he should never dare voluntarily to aspire until he not only fully comprehends the principles which must govern him in his duties, but also the peculiar conditions of the organism with which he is dealing. If there is anything of truth in the recent assertion of a distinguished obstetrical writer, that science is constantly recording new facts, which lead us to the conclusion that there is not a single fibre of tissue nor a single drop of fluid in the organism of the pregnant woman which does not pass through some modification, surely the so-called physiological processes of pregnancy and parturition border too closely upon a pathological condition to admit of being neglected or lightly considered. Nor with the conviction that such is the truth, can any intelligent and honest physician convince himself that his responsibilities are at an end when his patient is safely delivered—an idea which custom has made too prevalent in many localities. Not only the thousand external dangers which now surround his patient, and the vitiated state of solids and fluids, but the essential changes through which the organization of every lying-in woman must pass to free itself from the refuse of the excessive material required up to this time for fetal sustenance, demand days of close and intelligent watchfulness to see that every organ is performing its proper duty. To those of my hearers to whom a résumé of obstetrical work may seem uninteresting and unprofitable, I offer these thoughts in excuse for occupying the time kindly but injudiciously granted me by the President at our last meeting, in examining some of the more important subjects in obstetrical practice and endeavoring to gather up a few of the crumbs that have fallen from the tables of our masters since any such review has been offered in this Society.

ABORTIONS.

Abortions, from causes unavoidable and from the hands of those harpies, male and female, who hang on the skirts of the profession and earn their daily bread by the nightly murder of the innocents, unquestionably result in more fatality and leaves behind them a train of more serious conse-

quences than any other accident of pregnancy or parturition. Current medical literature abounds in reports of fatal cases, yet it is undoubtedly true that a very large per cent. are never reported. A recent writer has made the statement that over six thousand women die annually in the United States from attempts at induced abortion. In some such cases death probably results from violence, but there can be no question that nearly all cases of death from abortions, avoidable and unavoidable, are the results of retained secundines. Our standard works on obstetrics almost universally leave too much to the discretion of the accoucheur, as to their immediate delivery, and with such authority, joined with the entreaties of his patient and a fear of harmful interference, an inexperienced attendant is too strongly tempted to adopt an expectant treatment. Obstetrical and other journals have been replete, during the last year, with warnings against the fatality of such a course, and the opinion is rapidly becoming universal among the members of the profession that immediate and complete evacuation of the uterus by dilatation, forceps and curette, if need be, is the only protection against hemorrhage, septic poisoning, and many other accidents liable to arise from their retention. J. Braxton Hicks, in the *London Lancet*, advises this course under all circumstances, except when the patient is utterly exhausted from hemorrhage, which can be temporarily checked, when it is better to wait till the effects of the shock have passed. This able writer utterly condemns our venerable friend, the vaginal tampon, as inefficient, uncleanly and dangerous, recommending in its place the cervical tampon in the form of a sponge tent or some substitute for it. Dr. T. J. Alloway, of Montreal, in the *American Journal of Obstetrics* for February, 1883, also discards the tampon entirely, and strongly advocates immediate dilatation and the use of the curette in all cases of retained placenta in abortion; and in the same journal, Dr. Paul F. Mundé uses this forcible language: "The future safety of the patient demands that the secundines should be at once removed after expulsion of the fetus in every case of abortion in which such removal can be accomplished without force sufficient to injure the woman." In support of this assertion Dr. Mundé reports fifty-seven cases in which he resorted to immediate use of the curette and forceps in thirty-one, and to the tampon in only two. Notwithstanding this high authority, I think a large majority of the profession are still in favor of an early use of the vaginal tampon in abortions, but if not used *early*, all agree it is worse than useless. The general practitioner, as a rule, can have no knowledge of his case until he finds himself confronting a violent hemorrhage, which will admit of no delay. The tampon can readily be obtained, and when properly applied, can be relied upon to control the hemorrhage. It can be easily removed and reapplied as often as cleanliness or disinfection may demand. By pressure and reflex irritation it becomes a safe and valuable aid in dilatation of the os, and in a majority of cases where it is used, before possible danger can threaten, we shall find the entire contents of the uterus lying in the vagina, thus rendering further operative interference unnecessary. If this does not occur within thirty-six or forty-

eight hours, we cannot too strongly urge without further delay the dilatation and complete evacuation of the uterine cavity. I have always found the sensitive and educated finger the safest and most convenient instrument for this purpose when the os can be sufficiently dilated, otherwise I would resort to the curette and placental forceps.

FORCEPS.

Nowhere, unless perhaps in antiseptic midwifery, have we a more forcible illustration of the progress in obstetrical science than in the use of forceps. While a medical student I was told by a distinguished teacher of obstetrics, that in a large practice of more than forty years' duration he had applied the forceps only three times, and I was taught to regard it as a difficult and dangerous operation, only to be attempted as a "*dernier ressort*." Happily the day for discussing their value is passed, and they are universally accepted as among the most efficient aids of the obstetrician, although there is still reason to believe that in some localities too frequently the agonized cry for help—the lifeless form and desolate home—may justly charge its needless suffering and its lost hopes to an almost criminal timidity in their use. I can offer no more forcible argument against too long delay in the use of forceps than a brief reference to the record of my own practice, where I find no less than seven cases, mostly taken from the hands of midwives, in which the child was ascertained to be dead before the forceps were applied. We cannot fail to express our conviction from personal observation, that when greater reliance is placed upon a skillful use of the forceps by every practitioner and less dependence upon the use of ergot, the mortality in obstetrical practice will yet be not a little reduced. Since any review of obstetrics has been given in this society, Dr. Tarnier, of Paris, has offered to the profession a forceps constructed, it is claimed by the inventor, on scientific principles, with separate traction rods designed to facilitate traction in the axis of the pelvis at the point on which the head impinges; while in the handles he claims to have a sure index to that point. Tarnier's forceps, with its modifications, have excited much discussion among obstetricians, and seem to have been received with favor by many, both in this country and abroad, but so far as I am able to glean the opinions of its American defenders, they all agree that the range of its application is very limited. Prof. Lusk says, "For the upper two inches of the pelvic canal they are applicable, but for the inferior strait and the perineal groove they are most dangerous instruments." The eminent teacher, For-
dyce Barker, says, "Tarnier has supplied a want in obstetrical forceps which has never before been supplied, but its application must be limited to just that class of cases where immediate delivery is required and the head is at the brim of the pelvis, or in cases of moderately contracted pelvis. After you reach the curve of the axis of the outlet the instrument becomes a dangerous one, and should be removed." And Prof. T. G. Thomas adds to this testimony: "I have used the instruments where I have had to deliver the head at the superior strait, and have been exceedingly pleased with them, but would not apply them when the head is low in the pelvis under any circumstances. My

plan has been to draw the head well down and then complete the delivery with the ordinary forceps." Robert Barnes, Prof. Simpson, and other English writers cordially endorse a modified form of Tarnier's instrument. Certainly an enthusiastic endorsement from such high authorities of different nationalities, must compel us to acknowledge that Dr. Tarnier has presented to the profession an instrument of unquestionable value, and one which will undoubtedly maintain a permanent place in the armamentarium of lying-in hospitals and physicians of a large consulting obstetrical practice. But the important question to be decided by the general practitioner will be, not whether with Tarnier's instrument he may be able to deliver with less expenditure of his own time and strength, but whether its use is absolutely essential to the safety of mother or child—whether without regard to his own convenience, the same result may not be safely attained with the forceps in ordinary use, to which he has always been accustomed, as with the heavier and more complicated instrument of Tarnier in the hands of one whose experience in their application must necessarily be very limited. To aid him in his decision he has the opinions of a large number of able obstetrical teachers decidedly in favor of the older instrument. Prof. Braun, of Vienna, pronounces the forceps of Tarnier of little practical value, and still clings to his old forceps. Prof. Lazarewitch, speaking of the claim that they indicate the direction in which traction is to be exerted, declares that such direction can be indicated by no mechanism possible in the construction of forceps. Drs. Taylor, of New York, Wilson, of Philadelphia, and Reaney, of Cincinnati, do not recommend Tarnier's forceps to the profession for general use, and J. Matthews Duncan, of London, thinks they will never supersede the older form of instrument. Dr. Albert H. Smith, in an exhaustive paper read before the American Gynecological Society, asserts that the principle of Tarnier's instrument is by no means new, and that all the advantages to be gained by it are possible with the ordinary forceps. He thinks no traction should be made in the length of the handles, but that the extractive force should be expended in a firm and steady pressure with the palmar surface of one hand upon the lock in the direction of, or parallel to the axis of the pelvis at the point on which the head impinges, and a steady lifting upward of the handles in an opposite direction. This simple and comprehensive direction of Prof. Smith certainly commends itself to our consideration, and whether or not he succeeds in convincing the advocates of Tarnier of the truth of his claim, surely in his defense of the simpler form of instrument he will have the sympathy of a large number of the profession, so long as the endorsers of the new forceps unanimously admit, that it cannot replace, but must become an adjunct only, to the older form. So far as I am able to determine from my own experience, I think that the simpler forceps, properly constructed and skillfully used, are sufficient to deliver any case to which the forceps are applicable, without serious injury to mother or child. In a tabulated record of nineteen hundred cases of childbirth and abortion, taken from the private practice of my former colleague, Dr. Geo. W. Barr, and myself, I find forty-one cases of forceps delivery

without a single discovered injury to the parturient canal, except an occasional ruptured perineum. I say *discovered* injury, because we have only been taught within the last few years to search for a lacerated cervix after the use of the forceps; and this accident may have happened without being discovered. Dr. Alexander Duke presented at the meeting of the Dublin Obstetrical Society, in June of last year, an appliance consisting of tractors to be attached to any long forceps; and when additional tractile force is required, he attaches to the tractors a belt to be placed around the waist, and thus bring to the aid of the arms all the force of the whole muscular system.

Dr. Cole, of California, and Dr. Grainger, of Massachusetts, each presented a new form of forceps before the obstetrical section of the American Medical Association at the last meeting.

PUERPERAL CONVULSIONS.

The number and variety of therapeutical measures presented to the profession for the relief of puerperal convulsions is conclusive evidence of the inscrutable mystery which continues, despite all research, to surround this dreaded disease. Venesection, the hot bath and pack, quinine in ten grain doses repeated every two hours, morphia hypodermically in two grain doses, jaborandi, pilocarpin, tincture of stramonium in ounce doses, oleum tiglli, bromide of potassium, chloral hydrate, nitrite of amyl, and veratrum viride, are among the remedies which have been extolled, some of them as specifics, during the year just passed by members of the profession anxious to serve science and mankind, and yet, "*mirabile dictu*," statistics show that the death-rate remains practically unchanged. The theories advanced as to the pathology of the disease are so various as probably to render it quite impossible to decide upon any one which will be entirely acceptable to a majority even of the leading obstetricians. It must, however, be evident to all, that no single cause can account for the phenomena in all cases, although undoubtedly in all cases a predisposition to the attack exists in the abnormal condition of both fluids and solids of the pregnant woman. I infer the opinion predominates among the profession, that there is a form of puerperal convulsions in which the nervous system is mainly implicated, and which generally recovers with almost any or almost no treatment, and the suspicion has sometimes forced itself upon me, that many of the reported recoveries, under the use of remedies for the favorable action of which no explanation is given, may belong to this form. That there is a second form, apoplectic in its character, the brain being the principal seat of the lesion, and in which venesection and cathartics are the remedies *par excellence* although in my own hands, possibly from errors in diagnosis, venesection has been almost universally disastrous.

In the records of our private practice already mentioned, I find the report of fifteen cases of eclampsia, in four of which all the symptoms pointing to the apoplectic form, blood-letting was early and freely resorted to with a fatal result in three of the four cases. I can only claim the consolation of hoping, not on account of, but notwithstanding the treatment. In the MEDICAL AND

SURGICAL REPORTER of January 6, 1883, I find a report of four cases treated by venesection, resulting in two deaths and two recoveries; nor are these the only records that have fallen under my observation during the year, in evidence that venesection is no specific in this disease. A third form, more fatal in its immediate results, and more serious in its remoter consequences than either of the former, is the uræmic puerperal convulsions. Many prominent contributors to recent medical literature, among whom I find Schröder, of Berlin, Ingerslev, of Copenhagen, and Halbertsma of Utrecht, consider a large per cent. of puerperal convulsions to be of this form, due to retention of the urea from pressure or other interference of the renal circulation. I must confess my inability to discover any generally accepted plan of treatment in this form of the disease. I have seen about thirty cases reported during the year, and the variety in treatment has been nearly equal to the number of reporters. Prof. Schröder considers it an extremely dangerous and fatal form of the disease, and most urgently advises to terminate labor at once when albuminuria makes its appearance during pregnancy. (*Amer. Jour. of Obst.*, 1881). A prominent English writer on this subject says, "with our present knowledge of the disease we have no better plan than to follow the same general line of treatment as in uræmic poisoning in other forms of acute nephritis." Carl Breus, of Vienna, expresses great confidence in the hot bath and pack, and reports several cases promptly relieved of the œdema by this treatment, while for the eclampsia he considers chloral hydrate the sovereign remedy. Combined with such remedies as circumstances in each individual case might indicate, I believe no more rational plan of treatment has been proposed for the uræmic form of convulsions. Venesection also has its advocates in this as in other forms of the disease. When our cases can be watched and venesection be resorted to as a prophylactic at the first warning of trouble, I have no doubt, by relieving the blood pressure and thus arousing the organs of excretion into renewed activity, it may be of much value in warding off the attack, but for the relief of an established uræmic eclampsia, I must confess I should approach this remedy as a doubting Thomas. Dr. Barr and myself in our small experience of fifteen cases, have made it our invariable rule when pregnancy was near its term to deliver as rapidly as was consistent with the safety of the patient. We seemed to have obtained better results from large doses of chloral hydrate and bromide of potassium than from any other internal medication, in which our field of experiment has been somewhat extensive. Dr. Thomas Wilson has recently reported in an English journal, the rapid disappearance of albumen and a marked improvement in all the attendant symptoms in two cases of albuminuria in non-pregnant patients following the use of this remedy. This, of course, cannot be accepted as deciding anything, but should further trial confirm the observation, it may lead to an explanation of the favorable action of chloral hydrate in uræmic convulsions.

SUPPORT OF THE PERINEUM.

If to support means to watch over and protect.

from harm, I have failed to observe in recent medical literature any expressed opinion which would lead me to the conclusion that perineal support has any opponents. I have been able to distinguish in the various discussions very little more than a difference in methods to attain the same results.

Dr. Theophilus Parvin advises placing the woman on the left side during the second stage of labor, encouraging frequent respiration, and preventing all bearing down efforts, by anaesthetics if necessary. He objects to the use of the fingers in the rectum, as tending to increase excitability and nervousness, and advocates direct support of the perineum with the naked hand. If rupture seems inevitable, he would resort to episiotomy to save the anal sphincter.

Dr. A. H. Smith finds a solution of the problem in the management of the head rather than in direct support of the perineum. He diverts the strain from the raphé to the lateral parts of the perineum by making pressure with the thumb and fingers upon the presenting part of the head as it presses upon the raphé, thus changing the shape of the head, and relieving the tension at the threatened point. When the danger of rupture is imminent, he does not hesitate to make the lateral incisions, but applies to the cut surfaces a strong solution of carbolic acid to protect against absorption.

Dr. W. T. Howard, of Baltimore, has found nothing in his experience which acts so promptly in relaxing the perineal tissues, and permitting a safe passage of the head, as placing his patient profoundly under the influence of an anaesthetic. I have frequently convinced myself of the value of this plan, but would suggest strongly emphasizing the modifying adverb, lest the inexperienced thereby come to grief. Anything less than profound anaesthesia loses control of the patient's will, and the natural inclination to expulsive efforts becomes uncontrollable and irresistible.

After a fair trial of several plans, I have found no more efficient method to control the head and protect the perineum than that described in this society, I think by Prof. Goodell, of passing the fingers into the rectum, the patient being on her back, and directing the head into the axis of the vulva by pressure on the forehead and face as they are forced down, and at the same time watching the presenting part with the thumb, making backward pressure upon it when required. I think also that we should always recognize the fact that variations in the pelvic formation, as well as in the part presenting, must, in some measure, modify the amount and direction of the counter-pressure used. I do not hesitate to say it has been my experience to observe more serious injuries from the head being forced violently through the vulval orifice with an unprotected perineum, than from a careful use of the forceps. Immediate operation is almost universally advised in torn perineum, and not least among arguments in its favor is the aphorism, "a bird in the hand is worth two in the bush." I now know several women who drag out a weary existence with a floorless pelvis rather than submit to a secondary operation. To obviate this misfortune, Dr. Dyhrenfurth, in two cases of primary union, has powdered the surface of the

wound with iodoform, and immediately reapplied the sutures, with a favorable result.

EXTRA-UTERINE PREGNANCY.

Until within a few years, the unhappy victims of this misfortune were considered almost beyond the aid of science. Early diagnosis was exceedingly uncertain, and later interference a forlorn hope; but thanks to the introduction and perfection of antiseptic measures, a new era has dawned in operative surgery of the abdominal cavity, which is now explored with a boldness and confidence that a few years ago would have been considered little less than criminal, and the successful treatment of extra-uterine pregnancy has been one of its brilliant results.

Dr. A. D. Rockwell, of New York, has recently published an interesting report of seven cases in which the vitality of the fetus was successfully destroyed by the use of electricity.

Dr. Rockwell considers galvanism the preferable form, and thinks the strongest current compatible with the safety of the woman insufficient to induce abortion. Several other cases successfully treated by this method have been reported, but so far as I can learn neither a failure nor an accident.

Dr. Fränkel advises the early destruction and absorption of the fetus by the aspiration of the sac and morphine injections. As this plan in the uncertainty of an early diagnosis must be attended with more or less danger, electrolysis would seem the surest and safest measure yet proposed to destroy the vitality of the fetus, the most efficient to hasten absorption of the foetal tumor, and in case of error in diagnosis harmless to disturb a normal pregnancy. When we consider the slight probability of saving the life of the child, and the magnitude of the dangers which constantly threaten the mother, it becomes our evident duty to resort to this safe and simple plan of treatment at the first suspicion of extra-uterine pregnancy.

From an analysis of twenty-one cases seen by himself, Prof. Thomas recommends the destruction of foetal vitality by electrolysis, if discovered before the end of the fourth month. If operative interference were demanded later, he would resort to laparotomy or elytrotomy. In abdominal pregnancy, he would wait for the full term of gestation, and deliver by the same methods; but when the full term is passed, and the fetus dead, he would allow nature to choose an outlet, standing by to aid or anticipate her as circumstances might demand. In rupture of the foetal nidus, he would still intrust the case to nature, but with the strictest vigilance, and if hemorrhage or blood poison threaten the life of his patient, he would promptly resort to operative interference. The hemorrhage inevitable in the removal of the placenta and the danger of blood poison from its being left behind, renders laparotomy, in the opinion of Prof. Goodell and other operators, extremely hazardous during foetal life.

Dr. Martin, of Berlin, has endeavored to meet this danger by ligating the placental base *en masse* before removal. He then resects, as far as possible, and closes the sac-walls, cutting off all connection with the abdominal cavity, and draining through the vagina.

OXYTOCICS.

The use of ergot as a uterine stimulant in labor can claim few if any advocates in medical literature, although its value in maintaining post partum contractions and hastening uterine involution is attested to by many of our writers. Dr. Chahbazian, of Paris, has described an alkaloid of ergot which, given hypodermically in a maximum dose of one-fiftieth of a grain, is followed by no abscess or induration, and produces certain and firm contractions in from two to five minutes after its introduction. Such an alkaloid, if easily obtained and preserved, would be of great value in post partum hemorrhages, in which ergot, in its usual form, is almost valueless, from its slow and uncertain action.

There has been much and earnest discussion during the year as to the value and danger of quinine during pregnancy and labor. Dr. Bardell, of Colorado, is positive that it is not only harmless during pregnancy, but is one of our most trustworthy resources in threatened abortion, and after a trial in more than sixty labors, he pronounces it the safest and most reliable oxytocic at our command.

Dr. Campbell, of Georgia, after a long experience, writes, instead of withholding quinine from a fear it may produce abortion or premature labor, "I give it most punctiliously to prevent abortion in the malarial district of the south. Others have urged with equal earnestness that it is dangerous during pregnancy, and useless during labor. With such diversity of opinion, it would seem that until the medical millennium dawns, we must mainly rely upon our own experience and observation. I have given it in moderate doses in all stages of pregnancy for more than twenty years without observing a single unfortunate result, and in protracted labor with uterine inertia, I have thought it rendered positive and substantial aid."

LACERATION OF THE CERVIX.

The causes, symptoms, effects and the operation for the relief of this lesion, were so fully treated at a recent meeting of this Society, that no extended review will be in place or attempted by me. The subject has called out much discussion both in this country and abroad, and since Prof. Goodell's able address many data have been collected bearing on the results of the operation. While it seems evident that the operation may have an important influence as a cause of sterility, we cannot, on this account, condemn it, as it is by no means certain that the condition which demands it may not be as disastrous to successful pregnancy as the operation. So far as I can form an opinion from published reports, I conclude the liability to a second laceration in subsequent labor is very little increased. Evidence has accumulated that carcinomatous degenerations frequently take their origin from this lesion, and the possibility of preventing this dreaded disease alone justifies the operation.

To the accoucheur, we briefly suggest, as precautions, the same watchfulness in the use of the forceps within the os, as he employs to protect the perineum—the substitution of tireless patience for the injudicious use of ergot—anæsthetics in precipitate labors, and opium or other sedatives in tedious first stage of labor.

POST PARTUM HEMORRHAGE.

I can offer no more conclusive evidence of the dangers from post partum hemorrhage than the official report that four hundred and ninety-seven women died, in Great Britain alone, during the year 1881, from this accident; and many who survive, says a celebrated obstetrical writer, if they ever regain their health, do so after a long and perilous struggle. Several valuable papers have been added to the literature of this subject during the last year, which rather discuss the remedies already before the profession, and attempt to settle disputed questions as to their value and safety, than to present any new methods of treatment.

In reviewing the literature of the accident, I could but be forcibly struck with the truth of Prof. Thomas' remark, that so many individual remedies for hemorrhage have been brought forward, that the student is utterly dazed when he comes to the scene of action; and even men of large experience are often seized with hesitation concerning the common-sense line of practice by which they should be guided at the bedside. Failing by ordinary means to produce firm uterine contractions, Prof. Thomas carries the hand, thoroughly cleansed and dipped in strongly carbolyzed water, into the uterine cavity, sweeps everything out, and irritates its walls by passing the palps of the fingers over their internal surface. He believes no remedy to be compared to this simple plan in producing prompt uterine contractions, and if resorted to before the nervous system is entirely prostrated, it will check post partum hemorrhage in ninety-nine cases out of a hundred. In one case, where all other means had failed, he produced immediate and firm contraction, and probably saved the life of his patient, by passing a strong current of electricity through the womb, and he urges a more extensive trial of this safe and easily-obtained remedy. He does not favor intra-uterine injections, but when resorted to, prefers tincture of iodine, or still better the common vinegar, as recommended by Dr. Penrose, of Philadelphia, to the iron, as introduced to the profession by Dr. Robert Barnes which he would utterly reject, except as a last resort.

Dr. F. M. Madden, of Dublin, makes the statement of practical value, if supported by other observers, that the condition of the circulation is of much importance as an early indicator of probable hemorrhage. He has never observed a permanently quickened pulse during labor—that is, a pulse not regaining its normal rate during the interval of pains, that post-partum hemorrhage did not follow unless avoided by proper preventive treatment. Dr. Madden admits the dangers attending the intra-uterine injections of iron, but thinks we meet with cases in which the immediate danger of death from hemorrhage outweighs the dangers from the use of the styptic. Many prominent obstetricians still condemn, under all circumstances, the iron injections; but I believe a large majority of the profession agree with Dr. Madden that when other treatment fails and death seems imminent, we are justified in its use, with proper precautions.

PLACENTA PREVIA.

In no emergency which the physician is called

upon to meet in the discharge of his duties can it be said with more truth than in placenta previa, that the first requisite of the accoucheur is an ability to recognize instantly what can and what cannot be done. My own experience in this alarming accident has been very limited, but sufficient to convince me that no fixed plan of treatment can be followed in all cases. Hofmeier, of Berlin, has recently published a report of thirty-seven cases under his care, with the unprecedented mortality of only 2.7 per cent. He rejects the tampon, and relies mainly on the Braxton Hicks method of version, bringing down the feet, checking the hemorrhage by the pressure of the buttocks. In all cases, he gave ergot hypodermically, and washed out the uterine cavity with a five per cent. solution of carbolic acid. Among general practitioners I think eight out of ten still adhere to the tampon, unless special indications point to some other line of treatment. I have seen no more simple plan than the one advised by Prof. T. G. Thomas, of a tampon formed of a conical linen bag, stuffed with carbolized cotton (possibly styptic cotton might take the place of the the carbolized), the apex of which is forced into the os as far as possible, the vagina packed around it, and firm pressure maintained by means of a T bandage. We thus aid coagulation, dilate the cervix, and compress the bleeding vessels. As soon as the os is dilatable, if the hemorrhage is not entirely controlled, deliver at once. When the tampon fails, he resorts to Simpsom's method of removing the placenta, and leaving the child to be delivered by nature.

ANTISEPTIC MIDWIFERY AND ITS RELATIONS TO PUERPERAL FEVERS.

In no other department of medicine or surgery does antiseptis, in its broadest sense, play so important a role as in midwifery. Many physicians with a large surgical practice, embracing severe fractures and lacerated wounds of a character so extensive and serious as to jeopardize life, have rarely, or perhaps never, met with pyæmia as the result of such injuries, while there are very few who have not seen more or less fatality from the justly dreaded diseases, puerperal fever, septicæmia and pyæmia in women who have passed an easy confinement, without prostration or cause for alarm. In seeking for an explanation of the causes for the extraordinary dangers which overshadow the puerperal woman, it at once becomes evident that the external causes are far less potent than some intrinsic condition to be sought for within the organism of the patient herself; and when our attention is turned in this direction, we cannot fail to discover the object of our search. During the months of pregnancy the maternal organism is called upon to perform a double task, of self-support and the providing and elaborating material for the nutrition of the fetus. The increased work of nutrition must necessarily be supplemented by an increased exertion on the part of the excretory organs, to free the system of the excess of débris resulting from the additional demand for constructive material. As the term of pregnancy approaches, these organs, encroached upon by the expanding uterus, are pushed from their normal positions and crowded against the surrounding tissues, their circulation is inter-

rupted, and their energies are paralyzed to a degree that renders the proper performance of their duties impossible; and too often the system, overcome by the accumulated refuse, falls a prey to an attack of eclampsia. If the pregnant woman escape these dangers, the final act of parturition leaves the system prostrated by its preceding herculean labors, the blood under the most favorable circumstances vitally impaired, and if perchance a severe hemorrhage has occurred, in a still more deplorable condition.

The importance of post-partum hemorrhage in this connection, and the accepted fact that puerperal fevers are very liable to follow this accident, is too frequently overlooked in the immediate triumph of having delivered our patient from a present and alarming danger. It would seem that the overworked system might now be permitted to recover its exhausted energies, but physiological laws have otherwise ordained. The processes of building up and maintaining a new life have now been completed, and the material required for this purpose has not only become superfluous, but is rapidly to become an active source of self-poison, unless promptly removed, and the organs of absorption and excretion are required to perform this extra service. We here have an organism in the most unfavorable condition to resist the shock and ravages of an inflammatory process, but in the most favorable condition for the lighting up of such inflammation at the least indiscretion. If I have succeeded, however imperfectly, in reproducing a recognizable picture of the female organism during the pregnant and puerperal state, a slight examination of its salient points cannot fail to discover why a *materies morbi* which a non-*puerpera* will resist with slight disturbance, will in the *puerpera* light a fire which all the skill of medical science may fail to extinguish.

To this disturbed condition during pregnancy, and a failure to maintain a proper balance between the organs of absorption and excretion during the puerperal state, must be attributed most of the fevers of a more or less serious character which are so frequently observed after confinement, and for which we can discover no assignable external cause; and if antiseptic midwifery in its widest significance means an attempt to prevent blood-poisoning, whether *endosepsis* or *exosepsis*, it is evident its surest foundation must be laid during the latter months of pregnancy. Added to these certainly not fanciful dangers, are other important factors. Within the uterus we have an extensive wound with its open vessels, caused by the cleavage of the placenta, and along the parturient canal lacerations more or less severe, probably in nearly all cases present in some degree, all open doors for the unobstructed entrance of any poisons left within their portals or conveyed to them from without by the hand or instrument of the careless accoucheur or ignorant nurse. Dr. Barnes has suggested a still more extensive, and it seems to me, dangerous route for the transmission of poisons, in the whole surface of the mucous tract, denuded of its epithelium and constantly bathed in the infected fluids.

When we seriously reflect on these inevitable dangers, the important question must force itself upon us, how is the lying-in woman to be best

protected from them? and recent experience in medicine and surgery would seem to indicate that it is to antiseptic midwifery we are mainly to look for a solution of the question, preceded and rendered more effective, as I have already said, by the strictest watchfulness during the later months of pregnancy.

Having brought our patient to the moment of labor under the best conditions to resist the effects of poisons from within or from without, we should, during labor, rigidly adhere to the antiseptic laws which govern surgical operations within the abdominal cavity. The hands of the accoucheur and every other instrument which is to come in contact with the parturient canal, during or after labor, should be thoroughly disinfected, and as soon as labor is terminated, the uterus should be firmly and permanently closed by external irritation, oxytocics, and the pad and binder. This Dr. Barnes considers the foremost measure in the scheme of antiseptic midwifery, and says he has for several years been in the habit of giving three times daily for two months after confinement a mixture of quinine, ergot, and digitalis.

The next, and in my opinion by far the most important step, and one which must be taken before putrefactive changes can possibly set in, is the frequent and thorough washing out of the vagina with disinfecting injections of carbolic acid or permanganate of potassium, the application to every fresh rent or fissure in cervix or perineum, where it is possible for septic poison to gain admittance, of a strong solution of carbolic acid; and finally, the closure of the last portal against external infection by a constant application to the vulva of a thoroughly disinfected napkin. These measures are simple, easy of execution, and perfectly safe, and we have abundant proof in support of their efficacy in the reports of several lying-in hospitals published during the last two years. After the second day, Dr. Barnes strongly emphasizes the daily use of intra-uterine injections of a solution of carbolic acid, iodine, or perhaps better than either, sulphurous acid, one part in forty of water, and the same distinguished authority thus summarizes antiseptic midwifery:

"1st. Keep the door shut against the enemy by maintaining uterine contractions.

"2d. Prevent the enemy from forming and collecting by irrigating the parturient canal with antiseptic fluids.

"3d. Eject the enemy as fast as he effects an entry by keeping the excretory organs in activity.

"4th. Guard the lying-in chamber against the approach of foreign poisons.

"5th. Fortify the patient against the attack of the enemy by keeping up due supplies of wholesome food."

The habitual use of intra-uterine injections as a precautionary measure against puerperal fevers, seems to be almost universally condemned in this country, and to number among its opposers many of the leading writers in Germany, where it has been very extensively tested. Hofmeier, in the *Zeitschrift für Geburtshülfe und Gynäkologie*, reports having treated two hundred and sixty cases by intra-uterine injections, many of which suffered from attacks of puerperal fever which he could only attribute to the treatment; and Dr. Max Runge clearly ascribes an epidemic of puerperal

fever in the Berlin lying-in hospital to the same treatment resorted to as a prophylactic measure. But when through neglect or from any other cause septic poison has found access to the circulation, testimony of the favorable results of intra-uterine injections has been so voluminous and positive as to render it impossible to reject it.

Unfortunately, no definite course of internal medication for puerperal septicæmia has yet been proposed, which by its success can claim such universal support from the profession. Opium, stimulants, quinine and iron still hold their pre-eminence as remedies. I have noticed several cases recently reported as rapidly recovering under the use of iodoform and salicylic acid. Of the latter I have had no experience, but that the former too often proves ineffectual has been my bitter experience. I think there are many who do not yet despair that more extensive research into the relation of micro-organisms to septic poisons may lead to practical results in the discovery of a more successful plan of treatment in puerperal septicæmia and pyæmia, and cases have been reported which lend encouragement to this suggestion.

At a meeting of the Obstetrical Society of New York, April 4, 1882, Dr. W. M. Polk reported the rapid recovery of a case of puerperal septicæmia in the lying-in wards of Bellevue Hospital under hypodermic injections of phenic acid, which had failed to improve under the routine treatment of quinine, cold affusions, uterine injections, etc., and at the same meeting Dr. R. F. Weir reported having used the same treatment with the most gratifying results in cases of septicæmia in the surgical wards of the same hospital. Dr. Sloan, of Glasgow, in the *Lancet* for December, 1882, reports a well established case of puerperal pyæmia, despaired of under the usual methods of treatment, which promptly recovered by the hypodermic use of the oil of eucalyptus, preferred by him to carbolic acid as an antiseptic on account of its non-poisonous character. May we not hope that continued investigation in this direction may eventually result in giving us a more reliable and successful plan of treatment with which to contend against these fatal diseases?

How to Administer Santonin.

The *Med. Press*, April 4, 1883, says that Herr L. Lewin, in a recent paper on the above subject, read before the Medical Society of Berlin, finds fault with all the usual methods of administering santonin. According to his views, it should be given in its least soluble form, *i. e.*, in the form in which it will be the least readily absorbed, as the effect desired is not a general, but a local one. An oily solution of santonin undergoes, according to his experiments performed on animals, not the slightest absorption in the stomach, so that under no circumstances is any trace found in the urine. Almost any kind of oil may be employed, coconut oil, olive oil, cod-liver oil, or castor oil. He recommends that 0.2 gm. (3 grs.) of santonin be mixed with 60 gm. (2 oz. *cir.*) of oil and given in four doses. He thinks that a useful addition to the above would be that of an oil contained in santonica, the *oleum cinæ*, æther., for the reason that all æthereal oils have been shown to act as poisons on the lower forms of animal life.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

PUBLIC HYGIENE.

We desire to direct special attention to two subjects treated in the address of the President of the Pennsylvania State Medical Association, which appears in this issue.

1. In reference to a State Board of Health.

He wisely directs professional attention towards its importance, and decries, as all men ought, the flimsy excuse that "war among the *pathies*" has been the cause of its non-creation. He strikes the key-note when he says that it has not been legislated into existence because "there is nothing in it" for our law-makers.

For shame! We must again say, what we have already stated, that our own State and Ohio are the only large Commonwealths in this country that do not possess State Boards. While we are not very strong advocates of state and city health boards, believing that the millennium in hygiene or preventive science can only be reached when we have *national* administration of sanitary matters as we have national control of the postal service, yet, not being sufficiently sanguine to hope that the general public will agree with us, until they more fully realize the value of concerted action in the prevention of disease, we do feel that, under existing conditions, a State Board of Health is a great necessity.

A good physician has great influence with his patients; the State Society has 1,800 members; we do not fear contradiction when we assert that if earnest and conscientious efforts were made, each physician could convince at least one hundred men of the value of a board of health. This would bring conviction to the minds of 180,000 men, who, going about, sowing seed, would soon convince many hundreds of thousands more, until the pressure would be so great, and the public desire so unmistakable, that our legislators would be *forced* to give us what we *ought* to have had long since. We would therefore earnestly urge the members of our State Society to pay special heed to this advice of one in whom they have demonstrated their confidence by electing him their president.

2. Dr. Varian calls upon our medical schools

to make hygiene a part of their regular curriculum. We have repeatedly urged this step, and will continue to do so, until the dream becomes a reality. We have in our ranks many men whose span of life is nearly run; men who, by long, busy and upright lives, have amassed more than a competence. In the past, such men have frequently seen fit to erect during life everlasting monuments to their memories by endowing chairs, presenting libraries, or some similar munificence, to testify their high appreciation of our noble science.

We would suggest to such men, that the opportunity now exists to erect a monument to themselves, before the grandeur of which the famed monuments of antiquity would sink into insignificance. A great niche in history is reserved for the name of him who first endows a chair of Hygiene, in an institution whose field of instruction is as broad as is that of some of our leading medical institutions.

Let all men who realize that their sands of life are nearly run, consider seriously this suggestion of Dr. Varian's.

DIABETIC COMA.

The subject of coma and sudden death in diabetes is at present creating much discussion in professional circles in England. The *Lancet*, for April 7, 1883, gives in a leading article a resume of what has been said on the subject, principally by Professor Frerichs, of Berlin, and closes by saying:

The conclusion at which Professor Frerichs arrives is not, then, very satisfactory, but it shows how much yet requires investigation. There are probably various causes in operation, and the first group of cases differs markedly from the others. In it death takes place from cardiac failure; there are no nervous symptoms, and the characteristic odor of the breath and reaction of the urine are absent. It is due to cardiac degeneration, owing to rapid tissue-waste, and other unknown factors which may operate in preventing tissue regeneration. The symptoms of the second and third groups are those of intoxication. A series of changes take place in the blood, the final products of which—aceto-acetic acid and acetone—are known, but the initial products of such fermentation in the blood itself are unknown and difficult to ascertain, from the rapidity with which the process takes place. The value of the paper is enhanced by two elaborate appendices,

one by Dr. Ehrlich, demonstrating by means of iodine the invariable presence of glycogen in the renal cells at the junction of the medulla and cortex of the kidneys in diabetes, the presence of the same substance in other tissues and in inflammatory exudations being as constant as in the non-diabetic organism; and the other by Dr. Brieger upon chemical researches with respect to diabetic coma, particularly as to acetone and its allies.

While, of course, it will be very interesting to know the nature of the toxic agency, yet what we more especially want, is the knowledge how to combat it successfully.

THE NEW YORK ACADEMY OF MEDICINE AND THE NEW CODE.

When viewed dispassionately, the scene presented at the recent meeting of the New York Academy of Medicine can only be designated as disgraceful.

The by-laws of the Academy provide that no one can become a member who does not give his adherence to the Code of Ethics of the American Medical Association.

There were among the members many who did not recognize this allegiance, the President and Vice President among the number.

Dr. Austin Flint, Jr., offered a resolution calling the attention of the Committee on Admission to this by-law. In the discussion which followed some of the distinguished adherents of the new Code, in their excitement, made use of language unsuited for gentlemen, even though not directed by any code.

The motion was carried, and some of its opponents, recognizing the inevitable, immediately tendered their resignations.

We confess that we can see nothing but eminent fitness in the resolution—for of what use are by-laws if they are not observed?

TANNATE OF CANNABINE.

A few months since M. Frommüller presented tannate of cannabine as a very efficient medication to induce sleep without any disagreeable after effects. The dangers of the abuse of morphine are so great that any other agent capable of inducing similar hypnotic effects would be a veritable boon to the practitioner.

Mr. Hiller has experimented with the medication, and has found that it gives good results, particularly in the milder forms of sleeplessness. Its effects are less marked in serious cases of delirium tremens, in mania, and in subjects already habituated to narcotics. It may be ordered in powders:

R. Tannate of cannabine,	gr.xv.
Sacch. alb.,	gr.xx.
M. et divid. in cht. No. iv.	
S.—One or more at bedtime.	

NEWS AND MISCELLANY.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

The thirty-fourth annual session of the Medical Society of the State of Pennsylvania was held in Norristown, May 9, 10, and 11.

The Society was called to order on Wednesday, May 9, at 9 a. m., by the President, Dr. William Varian, of Titusville.

After prayer by the Rev. Joseph McCaskey, the address of welcome was delivered by Dr. Hiram Corson.

Reports of committees, officers, and delegates to other bodies were made, after which Dr. Oscar H. Allis, from the Committee on Schedule of Subjects for Medical Examiners, presented the following report:

Schedule of Subjects and Requirements of the Medical Society of the State of Pennsylvania. Designed as a Guide to Medical Examiners in Ascertaining the Fitness of Candidates for the Study of Medicine.

The following resolutions from the Committee on Medical Education were adopted by the Medical Society of the State of Pennsylvania, May, 1878:

Resolved, I. That all county medical societies now existing under the regulations of this Society, or which may hereafter be organized, shall, at the next meeting to elect officers, following the adoption of this resolution, or the next meeting of officers, when such society shall have been organized, and annually thereafter, be required to elect three members, to be called Medical Examiners, whose duty it shall be to examine all applicants for admission as students of medicine, under the tuition of members of this Society, and said committee shall withhold their certificate from any applicant, unless he be of good moral character, possess a good English education, and a sufficient knowledge of Greek and Latin to enable him to pursue his studies with advantage. And no member of any county society shall receive any person as a student of medicine unless he present a favorable certificate from this committee.

Resolved, II. That every member of a county society organized or which may hereafter be organized under the regulations of the Medical Society of the State of Pennsylvania, before receiving any person as a student of medicine, shall require him to enter into a contract to pursue his studies for a period not less than three years, and it shall be the duty of his preceptor to present him a certificate, countersigned by the secretary of the local society of which he is a member, setting forth the facts as above stated.

Resolved, III. That it shall be the duty of all members of the profession, holding allegiance to the Medical Society of the State of Pennsylvania, to recommend their students to attend only such medical colleges as rigidly enforce the full three years' course

of study in their curriculum, and otherwise conduce to elevate the standard of graduation.

DR. A. M. POLLOCK,
DR. J. L. STEWART,
DR. I. PIERCE,
DR. S. M. ROSS,
DR. D. P. MILLER,

Committee.

With a view to bring the foregoing resolutions again before the Society, and to devise means to make them more effective, a paper was read May, 1881, entitled,

"In what should preliminary examinations consist, and what steps should be taken to make them uniform throughout the State?"

At the conclusion of the paper, a resolution was adopted for the appointment of a committee to report at the next annual meeting a *schedule* of subjects, on which applicants for permission to study medicine shall be examined by the Board of Examiners of County Societies.*

The chair appointed Drs. Oscar H. Allis, Traill Green, W. R. Finley, J. B. Roberts, W. B. Ulrich.

REPORT OF THE COMMITTEE.

Requirements.

I. A written statement, previously prepared, setting forth the candidate's course of study.

II. An essay.

III. Writing from dictation.

IV. Spelling—oral, written.

V. Reading.

VI. Geography—Descriptive, physical.

VII. Political Economy.

VIII. History—Ancient, Modern.

IX. Geology.

X. Botany.

XI. Chemistry.

XII. Natural Philosophy.

XIII. Mathematics—Arithmetic complete; Algebra, through quadratic equations; Geometry, through plane geometry.

XIV. Languages—English, standard school edition of English Grammar; Latin, Cæsar's Com. 4; Virgil, 4; Cicero's Orations, 2; Greek: The Reader; Gospels; Xenophon's Anabasis, 2.

At the conclusion of the report, a resolution was offered referring the whole matter to a sub-committee, who should have power to act.

No report was called for from Examiners of County Medical Societies, as many of these were stated to be waiting for the report on Schedule of Requirements.

The amendment to Rules of Order offered by Dr. Mills was adopted, as follows:

Resolved, That Rule IX. of the Rules of Order be amended so as to allow a suspension of the rules by a two-thirds vote of the members present.

Under "New Business," Dr. H. H. Smith, of Philadelphia, offered a resolution designed to express the confidence of the State Medical Society in the *old* code, and to likewise express their decided disapproval of any departure therefrom.

The balance of the morning session was consumed in the reports of committees and the transaction of routine business.

WEDNESDAY AFTERNOON.

Dr. James Tyson, of Philadelphia, selected for the subject of his address in medicine,

"MALARIAL HÆMATURIA,"

chiefly as it occurs in the Middle States, although he completed his subject by a brief picture of the malignant form of malarial hæmaturia, as it occurs in our Southern States. His paper was based upon a study of seven cases, one of which was an instance of the so called hæmoglobinuria or hæmatinuria, in which there are no red discs in the urine, but simply the coloring matter of

*See Trans. Vol. XIII., Part II., pages 517 and 636.

the blood, resulting from their disintegration and solution. This patient was a negro; the remaining six were white men.

This interesting disease, mainly confined to men, is almost invariably traceable to malarial exposure, and is characterized by the paroxysmal or continuous flow of bloody urine. It may or may not be accompanied by other symptoms of malarial disease, as chilliness, coldness of the hands and feet, pallor and blueness of the face, sense of weariness, etc.

The urine is usually acid in reaction, sometimes neutral, rarely alkaline, always albuminous and contains blood discs and blood-coloring matter, or the latter alone. In the latter case, a granular debris, probably the result of disintegration of the blood discs, is present. Casts of the uriferous tubules are frequently, but not always, present; they may be hyaline, blood-casts, or red and granular, the latter being formed of the granular debris referred to.

The pathology is theoretical, the malarial poisons being supposed to cause the alteration in the blood and blood-vessels, which permits the transudation of the former. The morbid anatomy is also undetermined, although there is reason to suppose that changes suggesting inflammation are found in the kidney.

The disease has to be distinguished from cancer of the kidney and calculous disease attended with hemorrhage, and from other infectious diseases in which there is hæmaturia and hæmoglobinuria, as well as from the effects of poisons introduced into the blood. The history of the case, and the absence of pain and cachexia distinguish it from the first two, and the other symptoms of infectious diseases and poisoning from the latter. We must first determine whether the hemorrhage is from the bladder or kidney. The presence of casts, when present, point definitely to the kidney as the source of the blood; but they are not always present. Clots of blood rarely attend hemorrhage from the kidney, while they are common in hemorrhage from the bladder.

If the diagnosis is accurately made, the results of treatment are often brilliant. It is that for malaria. Quinine, in doses of three to five grains every three hours when the hemorrhage is continuous, until it ceases. Or, if intermittent, sixteen to twenty grains sufficiently anticipating the paroxysm, should be given. Mercurials may be combined with quinine. Iron, arsenic, and astringents have not been found of much service. The natural waters containing iron and alum may be expected to be of service, such as the Orchers Acid Springs of New York, and Bath Alum and other springs in Virginia, and some have a reputation in hæmaturia.

The "malignant" form of malarial hæmaturia, of which many more cases have occurred in the Southern United States during the past fifteen years, than previously, is much more serious and more fatal. The hæmaturia is here sometimes ushered in with a chill or two, or the bloody urine may appear at once. Large quantities of bloody urine are passed, it is said one or two gallons in twenty-four hours. The urine is porter-like, and the sediment sometimes almost tarry in consistence. There is obstinate nausea and vomiting of bilious and dark matter resembling black

vomit. Intense jaundice rapidly supervenes; sometimes in an hour the whole body is stained yellow. The jaundice is hæmatogenous. There may be fever, hot skin, and temperature of 104° to 106°, but the strength rapidly declines, and the patient often dies in from twenty-four to sixty hours, and if he recovers, convalescence is prolonged. The negro seems to be exempt.

Autopsies show the same intense coloration of the internal organs, and sometimes the spleen is enlarged.

The only curative treatment is by quinine aided by mercurials. Morphia and carbolic acid have controlled the vomiting. Stimulants are necessary.

Dr. R. L. Sibbet, of Carlisle, followed with a paper entitled

"OBSTETRIC NOTES."

The inexperienced graduate in medicine enters upon this department of professional work with a greater degree of trepidation than any other. As surgeon he may call in an assistant, as physician he may deliberate or prescribe a placebo, but as an accoucheur he must be prompt. He has no time to refer to books, nor can he, except in rare cases, ask for a consultation. For these reasons and others which might be given he has need for all the information he can obtain from his preceptor, from lectures and from carefully prepared works on the subject before entering the lying-in chamber.

This paper, specially addressed to the young practitioner, is based upon one hundred consecutive cases of confinement. To show the importance of careful study, as well as the percentage of accidents to the mother and to the child, this number will answer our purpose.

The statistics are as follows:

Number of confinements	100
Primiparous cases	22
Severe labors	7
Rapid deliveries	5
Instrumental deliveries	6
Placenta previa	1
Adherent placenta	1
Inversion of the uterus	1
Unusual hemorrhage	4
Rigid perineum	2
Rupture of the perineum (slight)	1
Puerperal convulsions	1
Puerperal mania	1
Case of twins	1
Mammary abscess	1
Number of deaths	1

The Children.

Number of males	53
Number of females	48
Cephalic presentations	96
Left and right occipito-anterior positions	94
Left and right occipito-posterior positions	2
Foot presentations	2
Breech presentations	1
Left elbow presentations	1
Both hands	1
Cord around the neck causing death	4
Craniotomy	1
Decapitation	1

Syphilitic taint 2
Deaths in utero or soon after delivery 11

These results in a hundred consecutive cases in town and country practice may surprise some who are not in the habit of noticing the particulars of each case as it occurs, whether important or unimportant. I confess that it requires an effort to state before you that even one per cent. of mothers and eleven per cent. of children died in these cases of confinement. It is well known that many physicians never speak of cases which terminated unfavorably in their practice. But how can we be useful to one another if we withhold the essential facts? How can we advance medical science if we do not give the statistics correctly? If practitioners would take notes of their cases, and permit them, as here indicated, in groups of one or more hundreds for publication in our Transactions, very valuable information would be secured. The percentage of accidents would be seen at a glance; inspection and comparison would not be so difficult; the study of statistics in the aggregate would be less irksome.

The most important of these cases may be given in brief; others may be referred to.

The first I shall mention is the case of placenta previa; both hands presented. It was a second child. With the use of anæsthetics and by version, delivery was effected. There was hemorrhage before and after delivery. With the use of restoratives and careful watching, the mother rallied; the child was dead. Profuse pyæmia followed, with the absence of the mammary secretion. Dr. G. W. Reily assisted.

A case of very severe labor occurred, with normal presentation, but contracted superior strait. It was also a second child. I used anæsthetics, and delivered with the Hodge forceps a large lifeless child. I immediately placed it in a bowl of hot water, and used whisky on the bruised scalp. With perseverance in the use of hot water and rubbing, a bright crimson color came to the face and limbs, and respiration was established. The mother and child are living and well.

Another case of severe labor did not terminate so favorably. A young woman of lymphatic temperament, primiparous, distant in the country and neglected by her husband and friends, took, some weeks before her time, diabetes insipidus, which produced eczema of the vagina and pudendum. During these weeks she had neither sleep nor rest. When I was called, there was no time to do much for either complaint. Tedious labor came on, and as soon as possible, I used anæsthetics, and with great effort partially delivered the head of a large child, using the Hodge forceps. I cut the cord, which was twice around the neck, and applied a noose by which an assistant made traction until delivery of a dead child was effected. The placenta was removed without difficulty. Two hours afterwards the mother died from exhaustion.

The case of decapitation, which was also primiparous, may be given. The feet presented. The midwife, making traction too soon, perhaps, succeeded in delivering a large child, except the head. Late at night I was sent for and had to ride three miles. I found a rigid perineum and an unyielding coccyx. It was impossible to produce rotation with the blunt hook, the occiput

being under the pubis, so I removed the body with the small blade of my pocket-knife; still I could not produce rotation. I then resorted to a blacksmith in the neighborhood, and succeeded in extemporizing a pair of forceps, with which I produced rotation, and removed the head.

The case of craniotomy may be mentioned. The face presented behind the pubis. The head lodged in the superior strait, and I found it impossible with the strong contractions to produce rotation. To save the mother, I punctured the head and used the craniotomy forceps. The child was removed with great difficulty. Dr. S. P. Ziegler assisted.

The other case of face presentation resulted more favorably. It was primiparous, and the labor severe. Instruments were not used. The mother and child are living and well.

One of the cases of rapid delivery referred to resulted in inversion of the womb. The mother had no time to get into bed, and knelt at the side of it. In this condition I found her. The cord was short. There was profuse hemorrhage, but the patient rallied. Steady and firm pressure upon the fundus restored the womb to its normal conditions.

Another case of rapid delivery produced a slight rupture of the perineum. Fifteen months previous an extensive rupture had occurred, which had not been recognized by the attending physician. The patient had suffered during this time. I removed the epithelium and restored the perineum, using three large silk sutures. Dr. S. P. Ziegler assisted.

These cases are sufficient to lead the young practitioner to reflect upon the responsibility of the work in which he is about to engage. His first duty, after a careful study of the subject, is to prepare for any emergency. In a country practice, he should carry with him a strong pair of obstetrical forceps, and if distant from professional assistance one or more pairs of craniotomy instruments. These should be reserved until the life of the mother is in danger. It will be noticed that I used instruments in only six per cent. of cases, and I do not now think I should have used them more frequently. Some practitioners use the obstetrical forceps in one-fourth or one-third of their cases, but I cannot endorse this practice. If they would set forth the results of their work, as indicated in this paper, we would be able to judge better of the propriety of making such frequent use of them. The lancet and the hypodermic syringe should always be carried, though in these one hundred cases I had no use for the former. In plethoric cases of puerperal convulsions, the lancet should be used first. In the case referred to, I used the syringe and the sulphate of morphia, and with good results. The repetition of the dose within five or six hours, should always be in diminished quantities. Sulphuric ether and chloroform in the proportion of two or three parts of the former to one of the latter, by weight, are indispensable. A small piece of sponge saturated with a mixture and placed in the hands of the female is convenient and safe, and is generally sufficient. Should the anæsthetic produce jerking of the limbs, it would be well to discontinue it, as I have seen one case of this kind, not included in these cases, which resulted in tetanus

and death. Ergot has been regarded as a necessary part of the accoucheur's armamentarium, but in my hands it has an uncertain value. In cases in which I desired its reputed effect, it has not given satisfaction. It is probable, that in many cases action is slow.

Thus prepared for professional work, how should the practitioner behave at the bedside of the parturient female? To this question there is but one answer; he should be a gentleman. He should be polite, agreeable, and hopeful. He is called on business of the most important character, and for the time being, he is master of the house. Inappropriate conversation should not be indulged in; the reading of a newspaper may betray an indifference which might not be pardoned. On the other hand, there may be too much attention. Digital examinations are not to be made more frequently than are necessary to determine the progress of labor.

The exposure of the female, except in extreme cases, should be avoided. The efforts which have been made by some practitioners to overcome the supposed rigidity of the perineum by the introduction of one or both hands into the vagina, before the descent of the head into the pelvis, should be limited to the half-bred Indians of New Mexico, among whom this practice seems to have originated. Nor does it appear that the support of the perineum, recommended by more respectable authority, is of much account. We should rather assist nature in her efforts to expel the product of conception unless there is great danger of a rupture. Inunction and rubbing, when the head of the child presses firmly upon the floor of the pelvis, may be useful if the parts are rigid; and in extreme cases, a lateral incision of the vulva might be made. When the head has passed into or through the inferior strait there should be no delay. The accoucheur should pass his forefingers and thumb around the neck of the child and makes steady and firm traction. It may require the strength of a strong arm. A short cord around the neck may make delivery more difficult. Three things may call for immediate attention; syncope, contraction of the womb, and respiration of the child. The application of cold water with the hand is a good remedy for all. The placenta should be removed as soon as the condition of the mother will allow of it; in cases of hemorrhage it should be removed immediately. A firm contraction of the womb should be secured before leaving the patient. Her soiled clothing should be drawn away, and a binder applied if she has suffered much, and she desires it. The babe should be made comfortable in a soft woolen slip, long enough to protect the arms and the legs. Cow's milk, and no other food, except the mother's milk, should be given to it.

A few words in conclusion on two points which belong rather to the after treatment. Puerperal inflammation is a serious affliction which carries off a large percentage of mothers annually. I have seen this contagious in the hospitals of Europe, where it has prevailed to an alarming extent in the practice of others, and in three cases of abortion produced, as I believe, by the females themselves, and one of them died. My senior preceptor, highly respected and honored, gave me the particulars in one of his lessons of instruction, of

three cases that he lost in less than a month by this disease. He changed his clothes, and washed himself from head to foot. He had a large practice at the time, but he had no more cases of puerperal peritonitis. I have since known a respectable practitioner to lose also three cases of this disease within twenty-four days. He too had a large obstetrical practice. Let us note also the fact, as given by Dr. Tanner, that forty cases of this fearful malady occurred in the practice of one obstetrician and his student, as an epidemic (so-called) in England. We need not look for the cause of this disease in the bacilli and micrococci of Pasteur and Lister and Koch (strain at a gnat and swallow a camel) when the causes are obvious and easily removed. The busy accoucheur, napping in his closed carriage between calls, or lolling upon his lounge in his office, is most likely to drop into careless, filthy habits. But let me say to the young practitioner, that you may be caught sleeping: you may have made an autopsy; you may have dressed some foul ulcer; you may have attended a case of erysipelas on the day previous to your call to the lying-in chamber. Would you obey such a call? There is a strong temptation. I have declined, and sent for another physician.

Agreeing that puerperal inflammation may spring up independent of any of the causes referred to and extend to the adjacent organs, what shall we use to prevent it? The old treatment of a hundred years ago—a dose of castor oil on the third day—is a miserable delusion. At no time have we greater need for our knowledge of pathology, physiology and therapeutics, and less need for routine practice, than in the treatment of the parturient female.

It has been my practice to administer from the first hour of labor, or as soon as called, cholagogues and anodynes in small quantities, often in very small quantities. These may be given in an agreeable form, in powders, in granules, in parvules, or in pellets. There should be no time fixed for the movement of the bowels. To give a compound cathartic pill or two immediately after delivery might be the best thing to do. It would certainly help to arrest any tendency to inflammation of the uterus or the mammary glands by relieving the organs of secretion, and the distended blood-vessels. The natural channels which carry away the excrementitious products of the body should certainly not be closed when several important organs are undergoing such rapid change.

Abscess of the mammary glands would very rarely occur if evacuants were used instead of tonics and stimulants. In the case referred to the mother of the parturient female thought it would not be necessary to make a third visit, and undertook the treatment with castor oil. The result was, that several extra visits were made by myself and a neighboring practitioner.

This paper is respectfully addressed to the younger members of the profession with the hope that some, at least, will be encouraged to collect statistics and to present them, as here indicated, for publication. These statistics would be specially valuable if collected from a private practice.

Dr. Hugh Hamilton, of Harrisburg, the

read a very valuable paper on "Artificial Alim-entation," which will appear in full in our next issue.

Dr. R. H. Chase, of Norristown, followed with a paper entitled

"INSANE ASYLUMS IN SOME OF THEIR RELATIONS TO THE COMMUNITY."

The principal portion of this paper is occupied in the refutation of the popular delusion that persons of sound mind are frequently sent to institutions for the insane, through sinister motives, and there indefinitely detained. The writer regrets that this erroneous belief has become disseminated to an incredible extent, even in the medical profession.

A number of distinguished alienists are cited whose experience confirms his statements. A typical example in point, from his own practice, is given in detail—considerable importance having become attached to this case from its recent publication in the *Phila. Med. Times*.

He also briefly alludes to the jury system of commitment, which is advocated as a remedy for this alleged wrong; the progress made in mental science is pointed out, and he speaks confidently of the advance that will be made in psychiatry in the near future.

He refers to the revision of the lunacy laws of the State, and closes with a short plea setting forth the relations which insane hospitals bear to the causes of mental disease, remarking upon the melancholy fact that the work of hospitals in restoring the insane tends to spread the disease by the mysterious laws of heredity. Yet this need give no cause for alarm, he says, for at the proper limit nature will station her forces of contro-
 version.

"CLUB-FOOT—A FEW SIMPLE REASONS FOR ITS EARLY RELIEF,"

was the title of a paper read by De Forest Willard, M. D., Lecturer on Orthopædic Surgery of University of Pennsylvania, Surgeon to Presbyterian Hospital.

Dr. Willard discussed the subject of congenital talipes from the standpoint only of the necessity for early treatment, and the great harm which would result from neglect. Moderate degrees of deformity became severe ones while the physician was wasting precious time in waiting for the child "to be old enough for operation." Corrective measures should be adopted from the day of birth, and the foot should never be allowed to remain in the deformed position. Manipulation and hand pressure were capable of curing the majority of moderate cases of club-foot, but as the hand could not be constantly employed, all possible adjuvants should be brought to bear. The foot should be forced into as nearly the normal position as the child's endurance will permit, a dozen or more times each day by the mother, firm traction being exercised upon all contracted tissues, whether muscular, fascial, or ligamentous. This force combined with massage and electricity, would develop the awakened muscles and elongate the contracted ones, while the opposite results

would occur if the weight of the clothing were suffered to lie upon the unsupported foot: especially if the child be allowed to rest upon its feet would most serious deformity of the bones occur.

To assist the manipulations described, it was necessary that the foot be prevented from assuming its abnormal position. Various methods of securing this end were demonstrated, all simple, inexpensive, and easily attainable. Sole-leather, cut roughly to the shape of the foot and leg, fitted while wet, and then dried in position, would answer well, and was capable of easy removal for frictions, shampooing, and stretching. Felt, binder's board, or tin, would answer the same purpose. Plaster of Paris also was of great use, especially when through ignorance or inattention the proper manipulations would be neglected. At first the limb should be fixed in a position as nearly straight as it is believed the parts will sustain the pressure. When dry, the plaster case could be sawed open, and then removed three or four times a day for stretching. New casts could be applied as rapidly as rectification of the foot advances. Silicate of soda, or starch, or any stiffening material, will answer, but are not equal to gypsum, as the foot must be held in proper position during the "setting" of the material, and nothing equals plaster in rapidity, especially if table-salt is added to the water.

To secure elastic traction, which next to the hand-pressure is most efficacious, it will be found best in infants to surround the leg just below the knee with a band two or three inches in width of "printer's blanket," "two-ply," as it is known in the rubber trade—simply gum with cloth facing; this cut to the proper length and with eyelets inserted, is laced in position, and a similar band is applied to the sole of the foot. Between the two is stretched a gum band, the size being graduated according to the strength of the child—sizes: 0 $\frac{1}{4}$, 00 $\frac{1}{4}$, 000 $\frac{3}{4}$, 0000 $\frac{3}{4}$, 5-inch, and 7-inch. Such as are used in holding large bundles of papers will be sufficient. The advantage of this substance consists in the fact that it does not absorb urine or fæces, that it can be easily washed, and that at the temperature of the body it is sufficiently adhesive to remain in position without slipping. Should the dressing show an inclination to turn upon the foot or leg, a strip of rubber "soling," "thin" or "medium" grade, can be used in its place, the roughness of which would effectually prevent any such tendency. "Gutta-percha sheet," one-eighth inch in thickness, also answers nicely, if dipped into hot water, and moulded to the parts. Any of these articles can be obtained by writing to either the Goodyear or National Rubber Co.'s stores in any city, and the cost would be trifling.

The great advantage of this form of dressing is found in the fact that it is capable of being frequently removed for stretching and friction, that it is light, and can be worn inside a shoe, by simply cutting a slit for the strip. Sole leather would answer for the encircling bands, but it is more absorbent, and hence not as cleanly for infants.

Another very important element in the use of this form of apparatus consists in the fact that without renewing it, the mother can, whenever holding the child in her lap, constantly exert her curative power by forcing the foot into its proper position. The pressure of the encircling leg band retards circulation less than would be the case in immovable apparatus.

Barwell's dressing, by means of which points for the attachment of a rubber band are secured, is a good principle, but can be better carried out by the plan just mentioned. Since the regular Barwell cannot be daily removed, and as it is very liable to be soiled in young infants, it is only applicable to older children. At the point of origin of a muscle, a strip of tin containing a loop of wire is fixed in position by adhesive strips and bandages; at the point of insertion another eyelet is made fast in a similar way. The rubber strap extending between these points should be as the circumstances require, an infant needing no more than a gum band used for papers, No. 0000 $\frac{3}{4}$ or 5-inch; others will call for elastic webbing or tubing into the ends of which hooks are inserted.

Neill's treatment could be also used, but is objectionable for more than temporary use, since ready removal for hand traction was a most important element in any dressing.

Elastic tension has the advantage of acting constantly, whether the child be asleep or awake, and in the course of a few months, by the proper combination of manipulation with the means already alluded to, it will be found that such great advance has been made in the treatment that tenotomy, at first perhaps considered inevitable, will now be dispensed with. Even in the severe cases, where section of the tendon is necessary, this preliminary treatment will prove to have been of great benefit, and the operation will be far less likely to be followed by relapse.

Where patients can afford a shoe, the same principle can be carried out by the simple plan adopted by the author, of riveting an arm to the ordinary stirrup used in steel uprights for club-foot shoes, at the end of which arm is an eye through which plays a catgut cord attached to an elastic webbing, running up to be fastened to a button at the top of the upright. The attachment to the foot is made in the shoe opposite the heads of the metatarsals. An inexpensive joint is formed opposite the metatarsal articulation, which permits motion in every direction as readily as a ball-and-socket joint, by simply paring down the sole for a half inch in front of the stirrup, to the thickness of a sheet of paper. If the child is not walking, and there is consequently no trouble from the admission of dirt, the toe portion of the shoe can be made separately from the heel, being joined to it in the sole only, and there by means of a strip of soft "upper leather." Such a shoe costs but little, and fulfills most simply and perfectly the indications required, *i. e.*, the rectification of the deformity at the calcaneo-cuboid and astragalo-scapoid articulations, and the stretching of the contracted calf-muscles and plantar fascia. Should the case be too greatly deformed to yield to these measures, tenotomy

can be subsequently performed, or other operative measures instituted, but the present discussion is purposely limited to early simple means of correction.

"THE WEARING OUT OF VACCINE PROTECTION AND THE EFFICACY OF RE-VACCINATION."

Was the title of a paper read by W. M. Welch, M. D., Physician to the Municipal (small-pox) Hospital, Philadelphia.

Jenner not only believed in the identity of small-pox and cow-pox, but even entertained the fanciful notion that cow-pox in the animal, was the original or parent form of small-pox in man. According to this view, vaccinia in man was believed to be small-pox in its primitive and mildest form. Hence the protection which resulted from vaccination was regarded as permanent; or, at least, as permanent as that afforded by once undergoing small-pox.

This pleasing but illusory doctrine was long entertained; but time and greater experience have developed an accumulation of facts which lead to a very different conclusion.

It is my purpose to show, *first*, that the susceptibility to small-pox, however thoroughly destroyed by vaccination, may subsequently return; and, *secondly*, that re-vaccination can be depended upon to destroy again this return of susceptibility to the disease.

Among the most valuable statistical data proving the first proposition—valuable, because there is no room to doubt the reality and efficiency of previous vaccination—are those collected in the British army from 1834 to 1838 inclusive. The regulations of the army required every individual connected therewith to be thoroughly vaccinated, excepting only those who had had small-pox; but re-vaccination was not then enjoined. The average strength of the army during this period was (including men, women and children) about 105,000; of this number, 1,025 were attacked by small-pox, and 122 died, giving a death-rate of 11.9 per cent.

The statistics of small-pox hospitals show that a large proportion of the cases of the disease occur among persons vaccinated in early life. During the great epidemic of 1871-2, 2,377 cases were admitted into the Municipal Hospital of Philadelphia, and of that number, 68 per cent. occurred in persons vaccinated in early life. During the recent epidemic—1880-81-82—there were 1,659 admissions, and 54 per cent. of these were post-vaccinal cases. The proportion of such cases is seen to be 14 per cent. less in the late epidemic; the explanation of which is, I think, that re-vaccination was more extensively employed then in Philadelphia, than ever before.

I shall endeavor to show still farther that the deterioration of vaccine protection is progressive—increasing up to a certain period of life with the distance of time from the primary vaccination. To prove this, I submit the following table, containing a classification of 2907 cases of post-vaccinal small-pox, which have come under my own observation: showing the

relative numbers and ages of persons attacked by the disease after vaccination, also the ratio of deaths to the numbers attacked at the various ages :

		Cases.	Deaths.	Percentage of Deaths.
Under 5 yrs of age.	{ good cicatrix,	1	0	
	{ fair	4	1*	
	{ poor	5	1	
	Total	10	2	
5 to 10 years . . .	{ good cicatrix,	11	0	
	{ fair	9	0	
	{ poor	26	8	30.73
	Total	46	8	17.39
10 to 15 years . .	{ good cicatrix,	45	2	4.44
	{ fair	18	2	11.11
	{ poor	36	4	11.11
	Total	99	8	8.02
From 15 to 20 years of age		388	47	12.11
" 20 to 25 " " " " " " "		745	96	12.88
" 25 to 30 " " " " " "		580	92	15.86
" 30 to 35 " " " " " "		356	64	17.97
" 35 to 40 " " " " " "		249	51	20.48
" 40 to 45 " " " " " "		154	38	24.67
" 45 to 50 " " " " " "		105	22	20.95
" 50 years and over		175	63	36.
Grand Total		2907	491	16.89

Doubtless, very many cases classified in the table under the headings of "poor cicatrix" were never successfully vaccinated.

The table, while it certainly shows a very gradual increase in the number of cases of post-vaccinal small-pox during the earlier periods of life, proves that the maximum numbers occur at the periods immediately following puberty; thus indicating that at this eventful epoch some change is brought about in the animal economy that lessens or entirely destroy the protective influence previously exerted by vaccination. This may be the case even where the vaccination had been most thorough and complete. I have seen small-pox occur in persons presenting more than twenty typical vaccine marks; and I have known deaths to occur when as many as twelve such marks were present. The sooner, therefore, the profession and the public fully recognize the necessity of re-vaccination in all persons at the age of puberty, if not earlier, regardless of the quality or number of their vaccine scars, the sooner shall we succeed in the noble work of preventing small-pox, or of cutting short epidemics of the disease.

If then vaccination of the highest degree of excellence fails to confer permanent protection against small-pox, how much less must be the protection which comes from vaccination of an inferior character—such, for instance, as results from the use of partially deteriorated virus. The deterioration or diminished efficacy of vaccine virus by long humanization is a question which has been variously regarded by different observers: being accepted by some as an axiom, and rejected by others as a mere fancy. For myself, I have no hesitation in saying that it is my belief that vaccine virus not only loses much of its vigor through a long series of human transmissions, but that it also

suffers in the durability of its prophylactic power.

Typical vaccinia, or that type of the disease which should result from the use of animal lymph or lymph of recent humanization, requires for its fullest development and completion not less than twenty-one days, and sometimes a much longer time; while long humanized virus not unfrequently induces a form of the disease which runs its course in about two weeks. The former is followed by a permanent, well-defined and characteristic scar; the latter, by a superficial and ill-defined scar.

It is true that vaccinia of short duration will destroy the susceptibility to small-pox. I have had ample proof of this. Furthermore, I would say that for vaccination after exposure to the variola contagion my preference is for humanized virus somewhat remotely removed from the heifer, on account of the more speedy development of the vesicle and the earlier appearance of the areola. But the point I wish to emphasize is, that the protection which results from vaccinia of short duration is not so durable as that which results from vaccinia of a perfectly typical character. Or, in other words, the prophylactic power exerted by long humanized virus, is less durable than that exerted by bovine lymph, or lymph of recent humanization. To prove this, after what has been said, it is, I think, only necessary to show that small-pox is more fatal among persons showing poor, or even fair vaccine scars, than among those showing good scars. My statistics show the death rate to be 9 per cent. among patients having good cicatrices; 16 per cent. among those having fair, and 27 per cent. among those having poor cicatrices.

Having shown the necessity for re-vaccination, it yet remains to say something about its efficacy. Let me say first, however, that undoubtedly there is a great deal of confusion in the minds of practitioners as to what constitutes successful re-vaccination. Many believe that unless the vesicle pursues the course of typical vaccinia, the disease is spurious and without value. But, certainly, there is no more reason why the disease induced by re-vaccination should be true and typical. As varioloid differs in various degrees of severity from true small-pox, so does vaccinoid differ from true vaccinia.

Some of the most conclusive proof of the efficacy of re-vaccination is furnished as the result of experience in various armies. During the Franco-Prussian war, the Prussian army, in which re-vaccination was carefully and systematically performed, lost by death from small-pox, under circumstances of great exposure to the disease, only 263 men; while the French army, in which re-vaccination was not enjoined, lost 23,468 men; and the latter army was at no time much more than one-half the size of the former.

During an experience of more than twelve years in hospital work, I am enabled to say that only very few patients have been admitted to the hospital with varioloid, who presented evidence of having been successfully re-vacci-

* This case, not at all severe, occurred in a very delicate child—a foundling—one year old.

nated, and these few have had the disease in so mild a form that death has not occurred in a single instance. No person entering the hospital in any official capacity—as a resident physician, steward, matron, nurse, laundress, or other employé—who had taken the precaution to be re-vaccinated before entering on duty has suffered from smallpox in any form whatsoever. But, on the other hand, I have seen a few employés in whom re-vaccination was for some cause omitted, become infected by the disease.

With such facts as these before us, the conclusion seems inevitable, that if vaccination were efficiently performed in infancy, and re-vaccination at puberty, if not earlier, we should begin to realize the truth of Jenner's assertion, viz., "*that vaccination is capable of extirpating small-pox from the earth.*" But whether vaccination will ever be so universally and wisely employed as to confer on mankind its greatest possible benefits is doubtful.

After the transaction of routine business, the Society adjourned.

In the evening, at 7.30, the President delivered his annual address (see page 505), after which the Society was entertained at a banquet by the Montgomery County Medical Society.

THURSDAY MORNING.

After prayer by the Rev. H. M. Kieffer, Dr. A. Craig, of Columbia, delivered the address in "Surgery," which will appear in our next issue.

Dr. E. O. Bardwell, of Emporium, followed with a paper entitled

"SOME REMARKS ON SCARLET FEVER."

I have been led to prepare a short paper on scarlatina, not so much by the fact that I have made a careful study and analysis of 176 cases, as by the fact that this study has confirmed me in the adoption of some views concerning this disease somewhat different from those held by many of the profession.

I shall not attempt to give a complete history of the disease, but merely a few points in the history of these cases, and the deductions drawn therefrom.

During the winter and spring of 1878-9, 150 cases of scarlatina occurring in and about Emporium were treated by Drs. DeLong, Heilman and myself, it being convenient and interesting for us to do so. We met nearly every day and compared notes and made urinary examinations. Dr. DeLong, the microscopist of the party, is well known throughout Cameron and the adjoining counties as a physician of skill and ability in the use of the microscope.

Of the 150 cases the urine from 80 was carefully examined, and in every one without a single exception was found either albumen, blood globules or tube casts: in 21 cases albumen was found without other abnormalities, in the remaining 59 cases epithelial cells from the tubuli uriniferi. Blood globules or tube casts were found, either with or without albumen. In 9 cases only, albumen was found during the first 4 days of the febrile movement,

but in no instance were tube casts or other microscopic abnormalities discovered before desquamation had commenced.

The disease as it prevailed at this time and place was neither mild or unusually severe, the temperature averaging at its maximum 105 degrees, reaching in several cases which recovered, 107 degrees, and the pulse 140, reaching in at least one case, which recovered, 200.

The throat affection was a source of much anxiety in some of the cases, and in all required some attention. Many cases were complicated by enlargement of the submaxillary and parotid glands, five of them to such an extent as to make the use of the bistoury necessary.

April 23, 1879, I was called in haste to see a case twelve miles distant, and the train being on time, I reached the house within an hour, when I was met at the door by the information that I was too late; the patient, a girl of twelve years of age, was insensible, and strongly convulsed every few minutes; her eyes were in a state of nystagmus, the pupils insensible to light and the heart pulsating at the rate of 200 beats per minute: she had voided no urine for twelve hours previously, and very little for two days; she had had an attack of scarlet fever three weeks before, but it had not been thought necessary to call a physician. The patient had been in this condition since 5.30 p. m.; it was now 8 p. m. I immediately ordered water to be made hot, and forced down her throat a large dose of compound jalap powder in solution, together with ten drops tincture digitalis. The digitalis with five grains of bitartrate of potassa was continued every half hour until 11 o'clock. The water was brought in as hot as I could bear my hand in it, and the patient was placed therein; she had her last convulsion while in the bath the first time. She was taken out shortly, wrapped in flannel blankets and a mustard plaster applied to the lumbar region. This process was repeated five times from 8½ until 11 p. m., at which time she recognized her father. At 12 o'clock a watery evacuation from the bowels took place, and her recovery from this time on was gradual but complete.

A similar case occurred about the same time, but it had been treated by a quack with irritant diuretics, and although regular medical attendance was at last called and much the same treatment pursued, the patient died comatose.

Soon after I was called to see Mrs. C. B., aged 33 years. In four days her temperature had reached its highest point, 106½°. It then gradually declined until the seventh day, when it commenced to rise again, and albumen began to appear in the urine. Her improvement was very slow, and she suffered much from insomnia. During the third week, against my better judgment, I administered morphia. She rested better the night following, but the next day she had excessive cephalalgia and uræmic vomiting. No urine being voided that day, I used the catheter, getting about two ounces, loaded with albumen, and also containing tube casts and blood globules. The next day small abscesses made their appearance in different

parts of the body. She was treated with hydragogues and hot fomentations as seemed to be required, and braced up with tonics, but improved very slowly. The ninth week, with a director, I evacuated a large deep-seated abscess in the left axilla. From this time on her recovery was continuous, though very slow, it being six months before she had entirely recovered her strength, which she finally did, however, and is now perfectly well in every respect.

I have noticed that in those cases where the temperature being high and the pulse rapid, the eruption has remained rather scanty; that the symptoms referable to kidney and mucous membrane lining the bronchial tubes, stomach, and intestines has been much increased in intensity, not as I believe by metastasis, but by a natural selection of those situations for the chief elimination of the morbid principle in that particular instance.

The pain in the chest, stomach, and bowels frequently met with would seem to indicate a certain amount of efflorescence in those cases in which it concurs, while the microscope furnishes irrefragable proof of the existence of inflammation and subsequent desquamation of the mucous membrane lining the tubules of the kidney.

The treatment of the whole number of cases was very much the same, varying only in minor details as the exigencies of the case seem to demand, but all based on the theory which the subsequent history of 176 cases supports to a marked degree.

By the study of these cases my opinion has been verified that the nephritic lesion is not a sequel, but a concomitant, and that it obtains in every case of scarlet fever to a greater or less extent. If this is true, then the kidney lesion is the most important feature to bear in mind, and is the primary source of danger, leaving out those exceptional cases where the throat affection assumes a diphtheritic character, or when the pyrexia is so excessive as to paralyze the nervous system and cause death by asthenia. Understanding the action of the kidney, and believing it contains a dangerous element, our treatment is in all cases, regardless of non-severity or malignancy, addressed to some extent to this factor.

In all febrile disorders the cardiac organ is weakened, the pulsations are weaker than normal and usually faster as well. As a direct consequence the muscular walls of the renal arterioles are lax, the high arterial tension which favors osmosis and the consequent separation of the urinary elements from the blood is wanting, and the amount of urine secreted is abnormally small. During defervescence in other pyrexia the urinary secretion becomes augmented as the condition of the circulation improves, and no bad results follow. In scarlet fever, however, the case is different: if proper remedies have not been used when the urinary secretion begins to be increased, the uriferous tubules may be so blocked up with desquamating epithelium as to prevent the passage of any urine into the ureters, and fatal uræmia rapidly result.

Theoretically, then, we desire from the first a remedy which shall increase arterial tension in the Malpighian bodies, mildly stimulate the secreting element of the kidney, and at the same time have a demulcent effect in passing over the irritated epithelium of the tubules. We have no one remedy which meets these indications, but in digitalis and potassium acetate we have a combination which will do the work required, and more—for the digitalis slows the heart's action, and perhaps has some apyretic properties as well. Belladonna increases arterial tension, but does not slow the heart, and is not so much to be depended on. The potassium is slightly stimulating, demulcent, and increases the secretion of urea.

From a scientific standpoint, this treatment is a natural corollary from the study of the pathology of this lesion, and it is fully borne out in practice. For the throat complication, the muriated tincture of iron is an excellent remedy, and its action on the kidney is favorable, as it increases the elimination of urea. For the cephalalgia, which is frequently excessive, potassium bromide should be used, as it is not only efficacious, but has a slightly diuretic action. Morphia or any of the preparations of opium should be carefully avoided, as after the first transient effect they decrease the urinary secretion and the elimination from the blood of all its constituents. The increase of temperature will usually need attention for several days, as the insomnia, jactitation, and other nervous phenomena which may exist, are caused by the excessive pyrexia. Quinia has to be given in large doses to produce any lowering of temperature, and it is then only temporary unless the natural time for defervescence has arrived. Such doses irritate the stomach and decrease the elimination of urea. Quinia in scarlet fever is worse than useless.

In tepid water we possess an apyretic, which is harmless and of decided benefit: it may be employed either by sponging the surface or by use of the bath or pack, according to the urgency of the case. During its use, the temperature falls, the nervous symptoms disappear or are mitigated, and the patient is soothed and restful, often falling into a quiet sleep immediately thereafter. When the temperature rises again, water may be used again, and the temperature be thus kept down to a point compatible with ultimate recovery.

In treating any complications which may arise, if I am correct in my views, it is important to administer only such remedies as will not have a deleterious effect on the kidney.

During the four years following this endemic, I have attended twenty-six cases of scarlet fever, with mortality *nil*. As far as the clinical history is concerned, they may as well be classed with the others in every way, as they were of about the same severity, followed the same course, and received the same treatment, and there is no reason for wearying you with their history in detail. As before stated, the 176 cases all received essentially the same treatment—that briefly sketched above. Of the whole number, five died: the one treated primarily by a quack, two which succumbed

within twenty-four hours, overwhelmed by the intensity of the attack at the onset, and two which died from the effects of diphtheritic complication.

A quack who pretends to be a homeopathist, had during this time, as nearly as I can estimate, about thirty cases, six proving fatal, not including the one which concluded to die on a physician's hands. Now if he used Hahnemann doses, it would look as though the let-alone treatment was not the proper thing in this disease; while if he used appreciable doses, as I am inclined to believe he did, it would appear that improper medication must have been injurious and fatal.

While I fully appreciate the value of rest, diet, and cold water, still my experience with scarlet fever, unlike that with many other diseases, leads me to believe that sometimes medication is markedly beneficial.

I am fully aware that the majority of these cases would have recovered without any medical attendance; but on the other hand I am equally certain that the medical agents employed saved some lives.

A mortality of 5 in 176 cases is rather low, and I believe that treated from a false pathological standpoint no such results can be obtained; and if the pathology is correct, then the above is the rational plan of treatment, and the science and practice of medicine have met in the treatment of scarlatina as they have in few other diseases.

Dr. E. A. Wood, of Pittsburgh, read a paper entitled

**"A DEFORMITY WHICH SOMETIMES FOLLOWS
DISLOCATION OF THE FOOT OUTWARDS
AT THE ANKLE-JOINT."**

After a severe injury, as a blow or a fall, by which the foot is dislocated outward, and by which the distal end of the tibia is contused, split, or impacted, but in which the luxation is the only condition manifest, it sometimes happens that the ankle is deformed by enlargement of the distal end of the tibia, by increased malleolar space, by turning of the foot outward as in *talipes valgus*, and by the foot presenting outside the axial line of the leg.

Injury of the end of the tibia is likely to be followed by inflammation and enlargement, and the degree of each will be proportionate to the severity of the force which caused the same. Enlargement must widen the malleolar space—space which the astragalus cannot fill. In this case, deformity is obvious. But there are other elements which add to the deformity. In the case before us, the internal lateral ligaments are completely severed, while the external lateral are not. When the internal malleolar space is widened, the intact ligaments which bind the foot to the fractured lower end of the fibula will keep the foot in contact with the latter bone, while the internal malleolus will project inwards. This distance between the internal surface of the astragalus and the internal malleolus, will retard or make impossible the repair of the internal lateral ligaments.

It will be seen that the deformity may not be apparent when the dressings are removed, say at the end of two months, but when the patient attempts to walk on the injured member, he finds it weak and tender. When he persists in bearing his weight thereon, he will soon begin to notice that the foot is not right, and the surgeon will then see that that member is turned outward, is outside the leg axis, and that the internal malleolus forms a very prominent tumor, almost touching the floor when weight is borne on the unsound foot.

If the surgeon is observant he will now see why the deformity exists; the intermalleolar space is abnormally widened, making repair of the internal lateral ligaments impossible or insufficient.

The only way to arrest the trouble and make the deformity the minimum, is to keep the foot in suitable dressings for a long time, and that time may be a year or years. At the shortest and the best it will be a long time.

Dr. William Pepper read a paper entitled a

**"CONTRIBUTION TO THE CLINICAL
STUDY OF TYPHLITIS AND
PERITYPHLITIS."**

After alluding briefly to the usual favorable course of ordinary cases of this affection, he dwelt upon the extreme importance of pursuing treatment embracing absolute rest and carefully restricted diet, until complete cure was effected, so as to avoid the very strong tendency to subsequent relapse. Allusion was made to the ulcerative and perforating forms, and he dwelt upon the importance of the early recognition of the tendency to abscess. Exploratory puncture should be made, followed by operation for evacuation if abscesses be detected. Cases were quoted illustrating some of the difficulties of diagnosis, and the advantage of operation. Especial stress was laid upon the strong tendency of cases of typhlitis to recur, and finally, unless treated with great care, to pass into a chronic form. Several illustrative cases were given, bearing on this point, which further showed that even where very frequent relapses had occurred, a complete and permanent cure might be obtainable.

Dr. S. W. Gross, of Philadelphia, read a paper on
**"THE THOROUGH REMOVAL OF CARCINOMA
OF THE BREAST,"**

in which he advocated the amputation of the entire breast with its superjacent skin and fat, no matter how small the growth may be or how sound the skin may appear, along with the removal of the fascia of the pectoral muscle, and opening the axilla, with a view to cleaning it out if the glands are found to be invaded by the disease. This mode of operating is indicated because the remains of the breast, the fat, the skin, pectoral fascia, and axillary glands, are the seats of recurrence, or rather of the continuous growth of portions of diseased structures which are left behind in the operations as usually performed. For these reasons, the operation which he suggests is alone adequate to effect riddance of the tissues in which reproduction takes place.

Dr. Gross has operated in the manner indicated

in twenty cases, of which only one died. Excluding one case, in which all diseased structures could not be removed, and three in which the history ceased with the recovery of the patient, he gave a synopsis of the remaining sixteen. Of these, nine, or 56.25 per cent., were failures, one having died, one having been incomplete, and seven having recurred within a year; and seven, or 43.75 per cent., were successes, the patients having remained free from recurrence for periods varying from eleven to fifty-six months, or twenty-seven months and a half on an average. Three of these living cases were presented to the Society, of which one was free from reproduction for sixteen months and a half after operation, one for three years and eight months, and one for four years and eight months. In the first and third cases the axilla was cleaned out, while in the second it was explored with the finger, but as it was free from disease, its contents were not disturbed. In all of these patients the cicatrices were soft, pliable, and freely movable on the pectoral muscle.

"THE TREATMENT OF PURULENT PLEURAL EFFUSIONS,"

was the title of a paper read by James C. Wilson, M. D., of Philadelphia, Professor of Diseases of the Chest, in the Philadelphia Polyclinic; lecturer on physical diagnosis at the Jefferson Medical College, etc., etc.

The changes that have taken place in the management of pleural effusions in the last two decades constitute an important advance in practical medicine. In its present form the treatment of these diseases, though less striking, perhaps, than the treatment of some other affections, is capable of results, in diminishing human suffering and prolonging life, not inferior to those of the most brilliant triumphs of modern surgery in other fields.

Thanks to the wide diffusion of the art of physical diagnosis, the recognition of considerable collections of fluid in the pleural cavity is no longer beset with difficulties in any case. Thanks to the courage of Trousseau and Bowditch, to the clinical studies of Traube, Fraentzel, and others, and to the ingenuity of Dieulafoy and Potain, the indications for the removal of effusions, when necessary, are now definite, and procedures at once effectual and safe are at our command. Great, however, as has been the improvement in the treatment of these disorders, it is evident, upon the most cursory review of the literature of the subject, that the progress of knowledge here, as elsewhere, has often been retarded by the weight of authority and the mutations of fashion in medicine. Notwithstanding this fact, the tendency has been in the direction of the recognition of the essential pathological condition and simplification of appliances and their use. It is with a view to furthering this tendency that I venture to lay before this Society the details of the plan of treatment that has proved in my hands very satisfactory, and to indicate at the same time the pathological considerations upon which the plan is based.

The physical signs of pleural effusions may, in general terms, be referred to two series; First, those relating to the absence of the lung in certain regions of the chest, such as absent or restricted respiratory movement, absent or greatly enfeebled respiratory murmur, enfeebled vocal resonance, and fremitus. Second, those relating to the displacement of the organs upon which the pressure of the accumulating fluid exerts itself. These are in the order in which they occur: vesiculo-tympanic or otherwise modified percussion resonance on the affected side above the line of the effusion and due to compression of the lung; signs indicative of downward displacement of the liver or spleen, and immobility of the liver upon first respiratory efforts; signs indicative of displacement of the heart toward the sound side; fixed enlargement of the affected side, especially in its antero-posterior diameter; and finally widening and fullness of the intercostal spaces, most marked at the base of the chest.

Besides the signs comprised in these two series there are others, as for example, egophony, which are neither constant nor necessary to the diagnosis.

Aside from hæmorrhagic effusions and those passive effusions affecting both sides known as hydro-thorax, with neither of which we are at present concerned, inflammatory fluid exudations into the pleura are of two kinds: on the one hand a fibrino-serous fluid, poor in cellular elements, and on the other, a thoroughly elaborated or even ichorous and fetid pus.

But the pathological distinction between these fluids is less marked than their gross characteristics. A few weeks ago I withdrew by aspiration at a single sitting from the right chest of a man who had been for a long time confined to bed, a large quantity of fluid. Of this, the first that flowed was of a straw color, and only slightly turbid; gradually, the as cavity contracted, and the tip of the canula was depressed into the more dependent part of the thorax, the fluid became more and more opaque until finally it presented the appearance of thin creamy pus. In fact, with few exceptions, pleural effusions are not primarily purulent, but serous. They become purulent by degrees, resorption not taking place, and the inflammatory process continuing. From the clinical point of view, however, the distinction between fibro-serous and purulent exudation is of the highest importance. Serous exudations into the pleura are capable of resorption; pus is not.*

The methods of physical diagnosis enable us to determine the presence of fluid, not its character. When, however, to the signs indicating the presence of fluid are added certain symptoms, such as great pallor and rapid emaciation, irritated fever with sweating and diarrhoea, the presumption that the fluid is pus becomes very strong. Nevertheless, large purulent exudations occasionally occur without any of these symptoms. The nature of the fluid may always be determined by an exploratory

*The limits of this paper do not permit me to note the exceptions to this general statement.

puncture. For this purpose a hypodermic needle is commonly employed. My own preference is for the use of the aspirator, the operation causing no more pain, and having the advantage of permitting the withdrawal of a portion of the fluid at once. It frequently occurs that the removal of a few ounces of fluid is followed by the resorption of large serous exudations that have resisted medicinal treatment.

If the exudation be found to be purulent, the treatment must be determined by the age of the patient. In young children repeated aspiration of the pus as it re-accumulates, frequently results in permanent cure. I have seen one case in which a single aspiration of a distinctly purulent pleural exudation effected a cure in a child four years old. In adults, however, the case is altogether different. After aspiration, the pus rapidly re-accumulates; repeated aspirations exhaust the patient, without tending to the obliteration of the cavity. It is vain to hope to effect a cure in an adult by means of aspiration. The diagnosis of empyema being determined, it becomes necessary to establish a thoracic fistula. To the question when? I reply, with as little delay as possible. If the exudation be large, a host of dangers imperil the life of the patient. He may perish of exhaustion from the constitutional disturbance, or of septicæmia. Heart-clot may form as a result of mechanical interference with the blood-stream in the great vessels by reason of the displacement of the heart. If the lung be long compressed, it will expand slowly and imperfectly, sometimes not at all. Necrosis of the pleura may occur and the pus find its way into a bronchus or through the diaphragm. Suffocation is in the former event a possibility, in the latter fatal peritonitis a certainty. It may find vent by an indirect or tortuous sinus through the chest wall, an accident not likely to save the patient the ordeal of an operation except at the cost of years of invalidism. Sub-pleural abscesses may form, and finally we must not overlook the risk of gangrene of the lung, of amyloid disease, of tuberculosis.

To the question, How is a thoracic fistula to be made? the answer is not so ready. We must consider the pathological condition and the real purpose of the operation. We must give heed to the dangers that are said to attend it, and distinguish those that are to be dreaded as real from those that are traditional, and, therefore, from those that are to be disregarded. The disease for which this simple procedure is curative, is one of the most serious of the inflammatory affections, and lends to the operation much of its own importance. I am not among those who make light of tapping the chest.

Finally, we must divest the procedure of unneeded complications, and seek to render it as simple as is consistent with the attainment of the object in view and the safety of the patient.

First, then, we have to do with an extensive abscess, occupying a serous space, the walls of which are pyo-genic. This pus-containing cavity exists at the expense of the surrounding organs, which are displaced to give it room,

and which tend to resume their normal position. This tendency, viewed in connection with the disposition on the part of the pus-forming pleural surfaces to adhesive inflammation and the formation of granulations when allowed to come together, and to again form pus when again separated, indicates the real purpose of the operation. This purpose is the obliteration of the cavity by the elimination not only of the fluid already formed, but also by continuous drainage of that formed after the operation. To permit the opening to remain closed, even for a few hours, is to retard the progress of the case by dilating the cavity, and thus again converting, at some point and for the time being, a reparative inflammatory process into a destructive one.

It is proper to state at this point my conviction that it is not in all cases possible to determine whether the empyema be primary or secondary, and that this question does not in reality affect the propriety of the operation if the collection of fluid be at all extensive.

The dangers of the operation may be divided into immediate and remote. The immediate dangers differ greatly according as we employ the bistoury or the trocar. As I believe the trocar to be the best instrument in all cases, I restrict myself to the consideration of the dangers attending this instrument alone. And as I likewise believe that a single opening properly made is better than the two openings of *through drainage*, I dismiss the consideration of *through drainage* with the remark that all the immediate dangers of making a single opening through the chest wall are greatly increased by making two.

The real dangers directly attendant upon the operation may be briefly enumerated.

First, the adherent lung may be wounded if the puncture be made at a point too high, or the diaphragm if at a point too low.

This danger is to be obviated by determining the areas of dullness at all points of the affected side, and the level of the base of the sound lung as a guiding line. The point of election is in the sixth or seventh interspace, in the line of the posterior axillary fold. To the objection that this is not the most dependent region of the cavity, I reply that as the pus escapes the diaphragm rises, and that a line some distance above the floor of the cavity before tapping speedily corresponds to the level of its floor after the operation. At the point indicated, the muscular wall of the chest is not so thick as farther back, nor are the integuments so sensitive as farther forward. Furthermore, in the recumbent posture this point is favorable to drainage by gravity.

Second, collapse may result from the too sudden withdrawal of a large collection of fluid.

This danger is to be averted by two expedients. Of these, the more important is the preliminary withdrawal of a portion of the pus by aspiration, a procedure which I practice in all cases for the following reasons, namely:

(a) To determine the resistance of the intercostal structures at the position of choice for the radical operation.

(b) To ascertain the precise character of the fluid.

(c) To reassure the patient by exhibiting to him the fluid thus withdrawn and to inspire his confidence by the temporary relief aspiration affords. And finally,

(d) For the purpose indicated, that is, to obviate the risk of collapse by the previous withdrawal of a part of the exudation. When the circumstances permit it, the preliminary operation should be practiced two or three days prior to the radical operation. The second expedient is the temporary arrest of the flow by mechanical means if collapse is threatened. It is needless to say that an opiate, preferably morphia hypodermically, and stimulants, are given prior to the operation to anticipate this danger.

The danger of striking against a rib, spoken of in the books, scarcely demands our attention; its avoidance is a simple matter of operative adroitness. When, however the ribs fall close together or overlap in consequence of the partial drainage of the cavity through a previously formed spontaneous fistula in the chest wall or a bronchus, it is occasionally impossible to complete the operation until after the resection of a rib.

The danger of wounding an intercostal artery by the trocar, is not to be feared. The relation of the artery to its rib and the shape of the trocar are such that it is difficult to conceive how such an accident should occur.

Of the remote dangers resulting from the operations I shall allude to two only. These are septicæmia, from infection through the freshly-abraded tissues, and sudden death in the course of subsequent treatment.

The operation by the trocar possesses, over that by the bistoury, important advantages in respect to the danger of purulent infection in the track of the wound, because the former instrument compresses the tissues and compels them into close contact with the drainage tube, thus preventing their immediate exposure to contact with escaping pus. The efficient disinfection of the instrument and the use of disinfectants to wash out the chest at once tend also to avert this danger, which is, in truth, one of the most serious attendant upon the treatment of empyema. On the contrary, the wound made by the knife exposes more extensive absorbent surfaces to immediate contact with the outflowing stream of pus.

Of the danger of sudden death during the after treatment, I can only say that it is of sufficiently frequent occurrence to invest the care of these cases with an enormous responsibility. It occurs in most cases from heart-clot; less frequently, as Bartels suggested, from sudden alteration in the position of the heart in such a way that the ascending vena-cava was bent upon itself and its emergence through the foramen quadratum; and occasionally from causes that are as yet wholly beyond conjecture.

The internal administration of the salts of ammonia during the course of the treatment, to lessen the danger of heart clot, and the habitual exercise of due caution in all the details of washing out the cavity, are all that our pres-

ent knowledge suggests in the way of averting the catastrophe of sudden death.

Finally, the operative treatment of empyema may be greatly simplified. It consists, in fact, of the perforation of the chest wall, the elimination of the fluid, and the use of a proper tube to effect continuous drainage and serve as the means of washing out the cavity with suitable disinfectants. Yet it has been complicated by various devices in nowise needed to secure the end in view—by some that have proved in fact positive hindrances to the attainment of that end. I have alluded to the dangers of *through drainage*. I hold that the cavity of the chest cannot be properly washed out or disinfected by means of a drainage-tube passing into the chest at one opening and out by a second. Certainly, it is impossible to apply, under such circumstances, Callender's principle of distention, by which alone the disinfectant solution can be brought in contact with all portions of the cavity-wall; whereas, if there be a single opening, this may be done with due caution at every sitting. Double canulæ also prevent the gentle application of the principle of distention, and are not available to cleanse or disinfect the cavity. All appliances designed to exclude the air are useless, and belong to the past. Metal canulæ, with ingenious caps or valves intended to retain the pus on tap, so to speak, are as irrational as they are ingenious. The drainage must be continuous, and the freest communication with the external air is desirable.

The operation does not call for general anaesthesia, nor is the administration of an anaesthetic always safe. The common practice of applying ice to the skin to produce local anaesthesia is to be condemned: it prolongs the procedure; it probably does not lessen the necessary pain, and it is painful in itself.

The thorough disinfection of all instruments, it has been stated, is essential, but neither the spray nor antiseptic dressings are needed. The statistics of this operation, to the present time, show no better results under Listerism than without it.

The main steps of the operation, and the subsequent treatment, may be briefly outlined as follows:

The preliminary aspiration. The puncture, by means of short trocars (not exceeding in length two inches), the canula being retained only until the pus ceases to flow, when a soft rubber catheter (Nelaton or Jacques) is slipped into position, and the metal canula withdrawn. Catheters are preferable to sections of drainage-tube by reason of the ease with which they can be introduced into the sinus by means of a probe. It is occasionally necessary to change the catheter, or to remove it to clean it.

The washing of the cavity by means of a ball syringe and a system of soft rubber tubing, the connections being made by sections of tapering glass tubes. This operation is to be repeated once or twice a day. The temperature of the water injected should be figures 1 or 2–50° F. and the amount of force used very slight indeed. At the first sitting no more should be

injected each time than one-fourth the volume of the pus withdrawn. This injection is to be repeated at each sitting until the water returns only slightly turbid or clear. After having used for this purpose many of the disinfectants in vogue, I have settled upon the mercuric bichloride as the most efficient and convenient. At first I used one part to 15,000, then one to 8,000, and finally one to 5,000.

In the intervals of the dressings, the patient wears a large pad of oakum to absorb the discharge.

As the cavity contracts and the discharge diminishes, the interval between the washings may be much prolonged; when the discharge becomes serous, and does not exceed two fluid drachms, the tube should be withdrawn and the sinus permitted to heal.

If a spontaneous opening has formed in the chest wall, the plan of treatment is not thereby modified. Such sinuses are badly located, oblique, often tortuous, and always ineligible for operative purposes. In such cases, proceed as though no spontaneous opening existed. After the operation, such openings speedily heal. Bronchial fistulae are equally without influence in modifying the treatment.

Since I have adopted the plan indicated in the foregoing sketch, namely, during the past six months, I have had under treatment five cases of pyemema—three in the Hospital of the Jefferson College, one in the Philadelphia Hospital, and one in private practice. Of these, three fully recovered, one died of heart-clot, and one is at present under treatment.

Following this, Dr. Charles K. Mills, of Philadelphia, read a paper on

"THE MEDICAL SERVICE OF INSANE HOSPITALS."

He discussed some of the best methods of rendering the medical service of these hospitals more efficient. Instead of having, as at Norristown, for instance, four physicians for more than 900 insane patients, there should be at least double that number. The individual examination of every patient should, in some way, be provided for, so that those suffering from mental diseases in the institutions receive the same attention, so far as diagnosis and treatment are concerned, as do other patients in general hospitals or private practice.

It is an old story, but one which cannot be too often repeated, that the physicians, superintendents and assistants, are compelled to do too much regular and irregular non-medical work.

Every large hospital for the insane should be provided with a board of competent and conscientious "consulting physicians," which should have an existence in more than mere name.

Dr. Mills referred to the appointment of a staff of visiting or consulting physicians to the Norristown State Hospital, giving as his view, that such should have been selected only from those who would agree to do the necessary work. He believed, with Prof. Seguin, that

the duties of such should resemble, as nearly as possible, those who were called upon as consultants in private practice.

Such staffs should be constituted, in the first place, of a few well-known alienists and neurologists, and secondly, of a limited number of physicians and surgeons representing the various branches of medicine—a surgeon, a gynaecologist, an ophthalmologist, aurist, etc.

Every large hospital for the insane should be provided with a competent pathologist and microscopist. Preferably, these officers should be residents of the hospital, but where the hospitals were situated near large cities like New York and Philadelphia, the services of competent and even eminent men in these lines might be secured, who could be summoned by telephone or telegraph to perform autopsies, or to whom specimens could be referred for investigation and report.

Some of the suggestions and provisions embodied in the report and act, framed by the commission appointed by Gov. Hoyt in 1882, to examine into the present system for the care of the insane in the State, were commented upon, and advocated as measures designed to promote the greater efficiency of the medical administration of institutions for the insane.

Dr. Henry H. Smith was chosen President of the Society for the ensuing year.

Philadelphia was selected as the place for next meeting.

After the transaction of routine business the Society adjourned.

The Microphyte of Yellow Fever.

The *Brit. Med. Jour.*, March 3, 1883, says that Dr. Carmona del Valle believes that he has detected the microphyte characteristics of yellow fever, and proposes to name it *peronospora lutea*. The germs of the cryptogam are found in the patient's excretions, and in the fluids of the organism, especially the blood and the serous discharge resulting from blisters. Dr. Carmona del Valle has also discovered in the matter vomited, besides spores, a large quantity of mycelia of various colors, black predominating. The vomito negro (black vomit), according to this author, is due to the presence of these black mycelia; and the blood has not any influence on the color. In urine, he has observed small yellowish granules, which give birth to spores. If rabbits or dogs be injected with this urine, they exhibit febrile symptoms, with increase of temperature, which last two or three days; and the urine of the animals under experiment presents the same kind of granules as those observed in that of yellow fever patients. Animals which have once been subjected to injection resist the effects of a second. In order to render an animal exempt from yellow fever, it is sufficient to inject into it a small quantity of distilled water containing the specific fungus of the disease. The spores of the *peronospora lutea* are present in the urine of yellow fever patients for a length of time after their recovery. Their presence, Dr. Carmona del Valle believes, is the reason why such patients are not subject to a second attack. To test the amount of danger of prophylactic injection, Dr. Carmona del Valle

performed it on himself without any bad result; his urine, however, for some time contained the characteristic granules.

Medical Association of Central New York.

The sixteenth annual meeting of the Medical Association of Central New York will be held at Association Hall, Nos. 55 and 57 E. Genesee street, Syracuse, Tuesday, May 15, 1883, at ten o'clock a. m. A resolution was adopted at the last meeting requesting the secretaries of the county societies in affiliation with this Association, to forward the names of deceased members in their respective counties to the Secretary, on or before the 1st of May and 1st of November, in each year. Also that members intending to present papers at the meeting, should report their titles to the Secretary instead of the President, as heretofore.

Among other subjects of interest, Dr. A. Clifford Mercer will exhibit specimens of bacilli tuberculosis under the microscope.

Lead Poisoning from a New Cause.

Silken thread, sold by weight instead of length, is sometimes adulterated with sugar of lead. A seamstress was recently admitted into the Leeds Infirmary suffering from evident lead poisoning. Upon questioning her it was found that it had been a common practice with her, when at work, to hold silk as well as other kinds of thread in her mouth, and that she had done this the more readily with silk, inasmuch as it often had a sweet taste. It will be found that the silk thread of the best makers is tasteless, whereas some inferior threads are sweet.

A Throat Electric Lamp.

At a recent meeting of the Leeds and West Riding Medico-Chirurgical Society, Mr. Margetson, of Dewsbury, exhibited an incandescent lamp, designed by himself, and used by him since October last in examining the mouth and throat. The globe was about half the size of a walnut. It can be held in the mouth for two minutes without discomfort from the heat.

The Philadelphia Polyclinic.

The Philadelphia Polyclinic and College for Graduates in Medicine has received for the various classes, in the last two and a half weeks, the fees of twenty-six members. Some of the departments are full, and will receive no more pupils unless by special arrangement for extra hours. The by-laws prohibit the admission to the classes of *free* pupils or of medical students.

To Detect Starch in Milk.

The adulteration of milk by starch can be readily detected by the following method: Add a few drops of acetic acid to a small quantity of the suspected milk; boil the milk, and after it has cooled, filter the whey. If there is any starch in the milk, a single drop of iodine solution will give a blue tint to the whey.

Women's Medical College.

At a meeting of the corporators of the Woman's Medical College held April 23, 1883, Dr. W. W. Keen was elected to the Chair of Surgery in that institution.

Items.

—Fluid extract of cocoa is said to cause anaesthesia of the pharynx when brushed upon the mucous membrane.

—"Don't be going to the funerals of your patients," said a physician's wife to her husband; "it looks too much like a tailor carrying home his own work."

—The alkaline tannates, *e. g.*, the tannate of sodium, is said by Prof. Pribram to be a very efficient diuretic, and useful in dropsies from nephritis.

—The Munich Medical Society has presented a petition to the Bavarian Government asking that the course of medical studies be prolonged from four years to five. The petition is widely signed, and appears to be favorably received.

Had cremation been made legal in France, the body of M. Gambetta would have been burnt, as his name appeared in the list of senators and deputies who intended to lay the subject before Parliament on the earliest occasion.

—At a large anti-vivisection meeting recently held at Manchester, England, three resolutions successively proposed by the originators of the movement were voted down, owing to the effect of a temperate speech on the aims of physiologists by Professor Gamgee, who was present.

—According to Ruggi the operation of excising the knee-joint has been performed in Italy forty-six times: thirty-nine for disease, five for angular ankylosis, and one for traumatic lesion. Thirty-two of the patients recovered, nine died. Secondary amputations were performed in the other five cases.

—Some alarm has been caused in Burslem, England, in consequence of the crier being employed by a chemist in the town to announce that a customer had by mistake been supplied with poison instead of magnesia. It is not yet known whether the person who made the purchase has been made aware of the mistake.

—The Russian Press notices a new step taken by General Tcherniaieff, at Tashkend, in establishing a hospital for Mussulman women, presided over entirely by Russian female doctors. This, it is said, is the first time that Russian doctors of the fair sex have been admitted to separate and independent practice.

MARRIAGES.

EGGERT—LEONARD.—April 25, 1883, at the residence of the bride's father, John B. Leonard, by the Rev. J. M. Bray, Geo. L. G. Eggert, M. D., and Miss Adda M. Leonard, both of Parker City, Pa.

MADEIRA—SHEARER.—On April 26, 1883, at the residence of the bride's father, Dr. James Y. Shearer, Sinking Spring, Pa., Dr. James D. Y. Madeira and Miss Alva J. Shearer.

FREUND—YOUNG.—On Wednesday evening, April 25, 1883, by the Rev. A. Spaeth, D. D., Dr. H. H. Freund to Miss Kate E. Young, both of Philadelphia.

DEATH.

WHITING.—April 16, 1883, at Pensacola, Fla., Dr. John Cary Whiting.

JENSEN'S CRYSTAL PEPSIN,

Strictly Inodorous and Tasteless, and Perfectly Soluble in Water without Acid.

(gr. j. of it will dissolve the boiled whites of two or three eggs.)

ADDRESS IN SURGERY,

BY ALEX. CRAIG, M. D.,
Of Columbia, Pa.,

Read before the meeting of the Medical Society of Pennsylvania at Norristown, Pa., May 10, 1883.

In the busy rounds of a general practice, where we are expected to keep apace with every branch of our profession, it would be impossible to note all the improvements and discoveries that leave their impress upon the rapidly-revolving wheel of progress; and yet, as I accepted the honor of presenting this report, I have endeavored to record a few of the most valuable as they came to notice during the year.

Much that is written, and that fills the pages of our journals, is composed of first impressions, and an impulsive desire on the part of the author or discoverer to place something new before the profession; and it is probably less my duty to bring before you the things that are new than to cull out those that have been fairly tried and awarded a place in the list of valuables.

In this we meet with some difficulty and diversity of opinion as to what is good and what is not.

In the hands of Ole Bull, the violin was full of harmony and sweet music, whilst in many others its sounds are as unpleasant as his were charming.

So it is with many of the late discoveries. There is a certain amount of skill or aptness required in their use, and what I offer you to-day will be my idea of general opinion, possibly colored somewhat with my own.

As an example of extremes, I know of none

more decided than that of the Esmarch bandage. But a few years ago its merits were beyond description. The idea of a bloodless amputation, with empty arteries inviting the ligature, relieved a terrible operation of much of its terror.

Later, we read of the sloughing flaps, the tendency to after-hemorrhage, and a number of other disadvantages that follow its use; and the question arises, is it an appliance of value, or is it not? From my own experience in its use, I would say it is very much as we make it. If judiciously used, it will perform its part most admirably; otherwise, it may be followed with unpleasant complications.

More recently, the theories of Professor Lister have been filling our journals to overflowing, which, like the Esmarch bandage, finds much of its real worth through the manner in which it is used. While no one doubts the efficacy of the various antiseptics, which have been so thoroughly tested of late, and their value amply proven, yet, in the many operations that require immediate attention, it would be almost impossible for the general practitioner to go prepared with a full outfit, as recommended by Professor Lister. The greatest fault to his plan of operating and to his mode of dressing wounds is that it is too cumbersome and complicated for general use. Its redeeming feature and the prominent principle contained in Listerism, and the one that can be used everywhere, and is of real value both to the surgeon and to the patient, is the perfect cleanliness it requires in performing all operations and dressing all wounds.

In the hospital, which should be supplied with all modern conveniences and improvements, and

where cases present themselves daily for surgical treatment, the atomizer, the medicated dressings, and everything that belongs to this doctrine, might well be a part of the paraphernalia, that the patient could have the benefit of it.

While on the subject of antiseptics, I feel it my duty to say a word in favor of the hydrate of chloral as a local dressing. I know it is not new, but in my hands it has proved so valuable, and is so seldom mentioned in this capacity, that I wish to introduce it anew to your consideration. Its chief advantages are its freedom from unpleasant odor, its power to arrest the secretion of pus, thus protecting against fetor, and its stimulating qualities, both to the raw surface and to the contused parts surrounding recent injuries.

Corrosive sublimate has recently been used in the capacity of an antiseptic, and is highly recommended and strongly endorsed by those who have tested its virtues. The strength of the solution used is from one part in a thousand, down to one in five thousand.

I take pleasure in referring to the efforts that are being made to teach the laity to give rational and useful aid to persons accidentally injured, prior to the arrival of skilled assistance. When we consider the thousands who are constantly exposed to bodily injury in the mines and on the railroads, and in our workshops, that even the ground is tilled and the crops harvested by machinery capable of doing bodily injury, then we can realize the importance of the proper education and training of the public.

In the heat of battle, where destruction is the order of the day, the surgeon is there prepared and ready to administer to the wants of the wounded; but not so in private life. There we expect to escape injury, and hence go unprepared for it. However, exposed as we are, I can readily see the value of a certain course of general training. From the time of injury until the arrival of the physician, the moments are often very precious, and frequently decide the fate of the injured one.

My reference to this subject is based upon some sad personal experience, and I confess I refer to it somewhat feelingly. Only recently I was obliged to amputate a hand which should and would have been saved if the patient had been properly cared for in the outstart. Indeed, if he had received no attention from his excited companions, it would have been better for him. The case was one of compound fracture of the forearm. Anxious to ascertain the extent of the injury, his associates exposed the affected parts by forcing up the numerous surrounding sleeves. The result

of this was free venous hemorrhage from the compression of the veins. To arrest this, the field tourniquet (a dangerous appliance for unskilled hands) was applied with sufficient force to prevent arterial circulation, and kept applied for some hours. Notwithstanding every possible effort was made a few hours after the accident to re-establish circulation, gangrene of the thumb and fingers followed, and amputation at the wrist soon became a necessity. The want of a little knowledge in this business cost this poor man one of the most valuable members of his body.

Although it is said by one of our leading journals "we take no roseate views of the great advantages resulting from elementary surgical instruction to the laity," I confess my faith in the principle, and sincerely trust that the efforts being made in this direction may be crowned with success.

The advantages to be derived by the physician in general practice from the post-graduate lectures offered us by competent teachers is a valuable step forward, and deserving of favorable mention here. Much of their teaching is calculated to illuminate the pathway of the general practitioner through the field of surgery.

As a thorough knowledge of anatomy is an absolute necessity to the surgeon, and as its study from the cadaver is in a manner prohibited by the laws of our State, I do not think it amiss to solicit the influence of this body to procure the passage of a statute that will permit its study without the risks and experience of the past. A law that would be of great service to the physician and surgeon, as well as to the public, is now pending, and deserves our combined influence and encouragement to secure its passage.

Many interesting and daring surgical operations have been reported to us during the past year, of which a large proportion are probably too hazardous to ever become practical. However, where it is the only hope for recovery, and death is otherwise inevitable, I believe the surgeon's knife is as much entitled to a place in the list of remedies as any other, and is justifiable, even though the bowel, the stomach, the liver or heart, are the parts requiring its use. Although the cases of this grave character do not present a large percentage of recoveries, yet enough are reported to justify such operations under certain circumstances.

Cardiac aspiration has been performed during the past year, but I have failed to read of a case that was benefited by it, and look upon it as too hazardous to be entitled to a place in the list of justifiable operations.

Reference is made in the *Medical Record*, for March 10, 1883, to a case of "Extirpation of the gall-bladder" which made a good recovery. For a fuller account of these operations than time will here permit, I will refer to the late report in surgery to the American Medical Society, made at St. Paul, Minn., for the year 1882, by Dr. Wm. A. Byrd, of Quincy, Ill.

Within the past few years one of the most important and valuable operations is that of *nerve stretching*. It has been especially beneficial in chronic sciatica, locomotor ataxia, and certain forms of paralysis, and in the treatment of such cases is entitled to consideration when other means have failed. The operation is a simple one, and not generally followed by any unpleasant results.

The surgeon meets with few more perplexing tasks than the cicatrization of burns, sloughs, or indolent ulcers. For this purpose the art of *sponge grafting* is taking a conspicuous place recently. A very pleasant and satisfactory account of the preparation of the sponge, and of the operation of grafting, will be found in the *MEDICAL AND SURGICAL REPORTER* for March 10, 1883, quoted from the *Brit. Med. Journal*.

The quality of the sponge, the manner of preparing, and the method of using it, are so well told in the article above mentioned, that I would refer you to it. The *New York Medical Record* for October 7, 1882, page 402, reports a number of interesting cases of this kind, with their treatment and results. The same journal for July 1, 1882, page 11, also gives an account of *skin grafting*, where some of the grafts employed were obtained from the rabbit, while others were human. Those taken from the rabbit adhered more promptly than the others, and showed no trace of their origin.

There is probably no class of injuries more common and certainly none more general than fractures, and none more likely to bring us before the public through the courts of justice; hence, while I may have nothing new to offer, I think it well to keep their consideration constantly before us. The principle of extension and counter-extension, with perfect approximation of the fractured extremities, holds good in all cases; but how to accomplish this is the question to be decided at the patient's bedside. Here we are often obliged to resort to some of Dr. Levis' "Surgical Expedients in Emergencies."

Next to the fractures involving the joints, there are probably none more unpleasant to manage than those of the femur. This is owing largely

to the difficulty we have in procuring perfect and continued rest of the parts; also to the action of the strong muscles surrounding, and to the fact that there is but one bone. Experience has taught me that the more simple the dressings to wounds of all kinds the better, so long as we can accomplish the desired end. So far as possible, I think it well never to disturb the original dressing of a fracture.

Get the parts properly and neatly approximated in the start, and endeavor to keep them so. If the seat of fracture can be kept exposed to view it is a great convenience, as you can carefully watch the progress of the case.

I borrowed the idea of a fracture bed from Dr. Truesdale, of Rock Island, Ill., quite a number of years ago, which has yielded such good results in my hands, and especially in fractures of any part of the femur, that I think it worthy of mention.

It is so constructed as to be readily converted into a triple inclined plane—the middle, or thigh plane, being an extension one. The patient is placed on the bed, with the pelvis so fastened to the body plane by means of a belt constructed for the purpose as to prevent any rolling, or lateral motion of the body. The foot of the broken limb is then attached to a suitable foot-piece, and placed in its normal position. The bed is now put into its triple inclined shape and the middle plane extended, by the aid of a cog-wheel and ratchet, until the normal length of the fractured bone is obtained. The lower part of the extension plane is provided with a trap-door for the accommodation of excrement.

By this arrangement it is unnecessary for the patient to be disturbed throughout the treatment, and very rarely have I found it necessary to use either a compress or bandage to the fractured limb.

Like the ordinary double inclined plane, the extension is made at the knee, while the counter extension is made by the weight of the body.

Another unpleasant fracture to manage is that of the patella. My best results in these cases have been treated with the aid of elastic belting. Placing the leg upon an inclined plane, the fragments are approximated, and held as closely as possible by the aid of adhesive strips crossed above the upper fragments, and below the lower one, (as the bone is usually broken transversely) and drawn forcibly together, attaching the ends of the strips to the sides of the knee. Next fix a solid compress immediately above the upper fragment, and another in like manner below the lower, with the aid of adhesive strips, and also with the aid

of adhesives fasten a double thickness of a rubber bandage, similar to the Esmarch roller, below the lower compress, bring it up over both, and fasten it carefully above the upper one, first drawing upward upon the bandage, and pressing the upper piece of bone down to its normal position. This completed, another adhesive strip should be drawn across the patella between the compresses and under the rubber, and attached to the sides of the knee.

The constant contraction of the rubber will soon overcome the retraction of the muscle, and union will follow with but little or no perceptible space between the fragments.

I have always made it a rule in amputations to save a joint when possible, provided I can preserve it with complete motion. I do this first, because the natural joint is better than the artificial one, even though the stump may be shorter than desirable, and also because the farther we operate from the body, the better are the patient's chances for recovery.

To amputate the leg immediately below the attachment of the ligamentum patella, only the head of the fibula will remain, which is likely to turn outward as union of the parts is completed, thus making a prominence that is both unpleasant and annoying when it comes in contact with the side of the socket of the artificial limb. I call your attention to this, because I have not seen it referred to in any work on surgery. The remedy is quite an easy one, for at the time of operating the head of the fibula, having no connection with the knee-joint, can readily be removed, leaving a neater stump, and thus obviating all the troubles above referred to.

Marked progress has been made in the past few years in the treatment of diseases of the eye, the ear, the throat, the skin, etc.; but as many have made their management a special study, and contributed liberally to the profession through the various journals on the different branches, I will not occupy your time farther, but will refer you to their writings.

A PAPER ON ARTIFICIAL INFANT ALIMENTATION.

READ BEFORE THE MEETING OF THE MEDICAL SOCIETY OF PENNSYLVANIA AT NORRISTOWN, PA.,

MAY 9, 1883.

BY HUGH HAMILTON, M. D.,

Visiting Physician to the Harrisburg, Pa., Hospital, lately Analyst to Pennsylvania State Agricultural Society.

The inattention artificial infant feeding receives,

and the valuable foods for sale, suggested a rational basis for such diet.

The explosive cry of the newly-born, the heaving trunk, the flattened nostril, prehensile lip, and pouting lower one, form a complete mechanism for the hydro-pneumatic problem of primitive existence through which the infant must pass.

The remarkable changes in the circulatory apparatus:

INFANT ASSIMILATION AS SHOWN BY PROPORTION OF BLOOD CORPUSCLES. AGED 15 TO 20 DAYS.

Time.	Corpuscles.	
	White.	Red.
Before 1st meal	1	150
$\frac{1}{2}$ half hour after 1st meal	1	155
3 hours after 1st meal	1	145
$\frac{1}{2}$ hour after 2d meal	1	100
3 hours after 2d meal	1	142
$\frac{1}{2}$ hour after third meal	1	92
3 hours after 3d meal	1	158

PROPORTION OF BLOOD CORPUSCLES IN INFANT DIET $2\frac{1}{2}$ TO 3 HOURS AFTER MEALS.

Age in Days.		MILK DIET.			
		Mother's.		Cow's.	
		Human Corpuscles.	Red	Human Corpuscles.	Red

61 to 90		185		160	
91 to 120		191		172	
121 to 150		210		180	

The new function of respiration and the assumption of assimilation by the digestive tract are subjects which, contemplated in detail, afford a fertile field for investigation. The processes in the alimentary canal form the main points of our thesis—namely, artificial infant alimentation.

Directing our thought to, first, the development of these functions in infancy; secondly, the progressive natural diet offered for its nourishment; and, thirdly, the artificial aliment which fulfils best the essential conditions of natal life.

The saliva is excreted slowly.

EXCRETION OF INFANT SALIVA.

Age.	Time.	Amt.
21 days	30 min.	15 grs.
56 days	2 min.	15 grs.

Of an alkaline reaction, its diastasic power is therefore limited.

CONVERSION OF STARCH TO SUGAR BY ACTIVE ADULT SALIVA OF EQUAL AMOUNTS.

Source.	Time.
Potatoes	2 to 4 hours.
Peas	1 to 2 "

Source.	Time.
Wheat	$\frac{1}{2}$ to 1 "
Barley	10 to 15 min.
Oats	5 to 7 "
Rye	3 to 6 "
Corn	2 to 3 "

The stomach juices, but partially excreted, are only those able to break albumen into readily assimilated forms.

The liver is slow to assume its functions, as illustrated by the icterus of early babyhood, and that bile is not excreted quickly is known by the constipation then frequent.

At the age of four or five months, the pancreas begins to secrete *trypsin*. The bowel juices are alkaline if normal. When teething commences, the liver and pancreas are often so swollen as to draw attention to the abdomen. The bile is then rapidly secreted, causing healthful evacuations, to the relief of the now plethoric sensorium.

The colostrum is at once of exceeding utility; its excretory cells irritate the stomach to peristaltic action, compelling the rectum to expel the meconium. See Fig. A.

FIG. A.

Ganglionic Nervous System of *Corydalis Cornu*.—Leidy & Haldeman.

The quantity of fats and sugar in it is immediately absorbed, supplying the necessary hydrocarbon for the rapidly living and growing organism, and its albuminous fluid contains an albu-

minoid especially formed to assist primary digestion. See Fig. 2.

(Mott.)

Like the product of the cow, the bovine curd is, however, of a much more permanent character; the reason, until recently, was undiscovered.

Meissner's classical researches upon digestive products developed a series of *a*, *b*, and *c* peptones, respectively known as syntonin, *para*-peptone and *dys*-peptone.

In 1875, Schützenberger, by a number of experiments, divided albumen into certain approximates. Albumen, when treated with dilute sulphuric acid, gave a gelatinous precipitate, slightly yellow, of weak acid reaction, insoluble in water, alcohol, or ether; of the empirical formula C₂₄H₄₂N₆O₁₂+H₂O, named by him HEMI-PROTEIN.

In the filtrate there was found an amorphous material of a very weak acid reaction, having the formula C₂₄H₄₀N₆O₁₀, designated HEMI-ALBUMEN—

the filtrate from this substance vigorously reduced Fehling's solution.

Keuhné, in 1876, presented a scheme upon the digestion of albumen as follows:

SPLITTING UP OF ALBUMEN BY GASTRIC JUICES.			
Albumen.			
Anti-Albuminose.		Anti-Albuminose.	
Anti-pep- tone.	Anti-pep- tone.	Hemi-pep- tone. Leucin. Tyrosin, etc.	Hemi-pep- tone. Leucin. Tyrosin, etc. Due to action of Trypsin.
Anti-albumid (the Hemi-protein of Schützenberger) is insoluble in gastric juice, but soluble in a dilute solution of soda, then it is easily digested by trypsin.	Anti-albumat (the Parapeptone of Meissner) is an abnormal result of digestion due to insufficient pepsin; it is, however soluble in gastric juice, but not absorbable until in alkaline contact with trypsin.	Anti-albumose, or syntonin, is unaltered by stomach juices or trypsin, therefore is a true anti-peptone, and readily absorbed upon reaching the alkaline stage of digestion.	Hemi-albumose (Schützenberger's Hemi-albumin). It is difficultly soluble in cold, easily in hot water, in dilute alkalies, also in pepsin and through trypsin readily changed to Hemi-peptone, when it separates into Leucin and Tyrosin, etc. Hence it is observable that albuminous matter is parted by gastric juice into two groups, allowing early and late digestion. The anti-group is slowly absorbed, while the hemi-group is readily broken into further approximates.

Anti-*Albumid* (the Hemi-protein of Schützenberger) is insoluble in gastric juice, but soluble in a dilute solution of soda, then it is easily digested by trypsin. Anti-*albumat* (the Parapeptone of Meissner) is an abnormal result of digestion due to insufficient pepsin; it is, however soluble in gastric juice, but not absorbable until in alkaline contact with trypsin.

Anti-*albumose*, or syntonin, is unaltered by stomach juices or trypsin, therefore is a true anti-peptone, and readily absorbed upon reaching the alkaline stage of digestion.

Hemi-*albumose* (Schützenberger's *Hemi-albumin*). It is difficultly soluble in cold, easily in hot water, in dilute alkalies, also in pepsin and through trypsin readily changed to Hemi-peptone, when it separates into Leucin and Tyrosin, etc. Hence it is observable that albuminous matter is parted by gastric juice into two groups, allowing early and late digestion. The *anti*-group is slowly absorbed, while the *hemi*-group is readily broken into further approximates.

Albumin.	
Anti-Group.	Hemi-Group.
Anti-Albuminid (Heminpro- tin)	Hemi-Albuminose and pep- ton.
Anti-Albumat. (Para- peptone).	Hemi-pepton.
Anti-Albumose (Syntonin).	
Anti-pepton.	

Dr. T. Schmidt, in his inaugural dissertation, *Moscow*, 1882, thinks the amount of *hemi-ALBUMOSE* in human and cow's milk forms the main difference between them. From his experiments, if five (5) volumes of 2% solution, hemi-albumose, is added to one (1) of neutral cow's milk, rennet extract does not coagulate it for at least twenty-four hours. Should the reaction of the milk be acid, the mixture gives a flocculent precipitate, with no tendency to agglutinate or shrink, the serum remains milky as in human milk, when treated with rennet without hemi-albumose.

THE AMOUNT OF HEMI-ALBUMOSE IN HUMAN AND COW'S MILK AND AN ARTIFICIAL MILK ON THAT BASIS.

Milk Proteids.	Human	%	Cows	%	Theory requires %	Artificial
Casein ;	.6573	49.8	3.1666	87.3	Constant.	87.3
Albumin	.3382	25.7	.2970	8.2	+37.3	45.5
Hemi-albumose . .	.3224	24.5	.1672	4.5	+38.3	42.8

(T. Schmidt.)

HEMI-ALBUMOSE has the quality of being soluble in an alkaline liquid at 55° C. (131° F.) charged with carbonic acid gas.

The chemistry of albuminous digestion leads us to see the reason that human milk is so admirably adapted to the little body dependent upon it.

If, from imperfect female development, the mother is unable to nourish her offspring, the acute causes of disease prevent, or its sad results deprive the babe of suitable nutriment; then intelligent medical advice is of vital moment. What to recommend? What to avoid?

Dr. Hiram Corson, in 1870, published a pamphlet in favor of *undiluted* cow's milk for infants.

To physicians not in cities a certain fat percentage in cow's milks may be relied upon. The task of forming infantile diet, is comparatively easy from the recent chemical information obtained.

Concerning the milk from *one* cow, in an exhaustive paper before the American Academy of Arts and Sciences, Prof. S. P. Sharpless, of Boston, says: "A uniform diet for a child will be much better secured by mixing the milk of a number of cows than when it is attempted by trying to secure that of a single one. Since, as we see (my friend gave the results of 2,209 analyses of cow's milk, from 10 countries, by 20 different analysts), the milk of any one cow varies very considerably."

DIFFERENCES IN COW'S MILK.
Cow's Milk.

R. Rear . .	2.73	3.61	4.72	61.
L. " " . .	2.13	3.48	4.88	64.

(Sharpless.)

A leader in a late London medical journal re-

marks upon the discrepancy of human milk analyses, and how misleading they are when only proportions between casein and albumen are deemed sufficient to account for the unsatisfactory behavior of some animal milks:

RELATION OF CASEIN TO INFANT MORTALITY.

	Human	Asses.	Goat.	Cow.
Casein to 100 parts				
Albumen	122	155	173	2.37
Living Infants . . .	100%	73%	20%	17%
No. Used		38	42	6
No. Dead		10	34	5

The problem is yet exceedingly questionable, to suggest a suitable diet for infants.

The variation in the product of milch cows is notorious; what must it be in a sensitive animal like the human female?

The mortality in infant institutions is a pointed comment on our progress in this direction, and a matter of vital importance to our national existence.

Dr. A. V. Meigs, of Philadelphia, after a careful survey of the subject, advises condensed milk diluted with six (6) volumes of water, while the proportion of fats is completed by the addition of cream. He states in a foot-note that his cream had but 12 per cent. of fats. Where will he get his fats to add to the condensed milk liquid?

Dr. Keating, in an able lecture, depicts his difficulties in the effort to substitute *gluten*, a vegetable diastase, for the animal diastase, *saliva*. A matter here demands attention, namely, that *vegetable* albumen, gluten, and maltose are not animal

albumen, saliva, and lactose, though like unto them—because of the relation they sustain to assimilation by an organism.

CHEMICAL ISOMETRISM.

Cellulose.	Cane Sugar.	
Starch.	Milk " (lactose.)	
Dextrine.	Malt " (maltose.)	
$C_{12}H_{20}O_{10}$.	$C_{12}H_{22}O_{11}$.	

Possibly better illustrated by the disposition of the letters T, A, and R, when being transposed to read TAR, RAT, ART, words of very dissimilar significance.

If nothing but these artificial vegetable foods are procurable, a child may exist until able to take substantial animal diet.

Artificial foods, microscopically, which divided themselves into the following classes:

1st. Those containing MORE *gluten* than ordinary flour:

Franklin Mills Entire Flour.

Hawley's Liebig's Food.

Arlington Wheat Meal.

Mead's Milled Wheat Flour.

Baby Sop.

Those containing *gluten* EQUAL to ordinary flour, which has GLUTEN 3.50%, STARCH 63.64%:

Gluten Flour, N. Y. Health Food Co.

Savory & Moore's Food.

Horlick's.

Those containing LESS *gluten* than flour:

Ridge's Food.

Mellin's Food.

Victor's Baby Food.

Gerber's Food.

Potato Starch.

N. Y. Food Co.'s Flours—several brands.

Prof. A. R. Leeds examined these foods chemically. See table on page 543.

Upon these two bases you can judge microscopically and chemically respecting these foods. One of two conclusions forces itself upon our minds—that Liebig's theory of necessary change of starches to sugar is essential to assimilation; or, that the miscellaneous experience of the profession finding successful results, even from these foods, shows there still exists an unknown factor that brings to households sorrow and to the nation loss. We do, however, reach this conclusion: *That the use of mixed healthy cow's milk, rendered alkaline by bi-carbonate of soda (BAKING SODA, not powder) with the addition of a tablespoonful or two of good cream to one-half pint of milk, then heated to 55° C. (131° F.) and afterward sweetened by a strong, freshly-prepared syrup of milk sugar (lactose) forms the most admirable ARTIFICIAL INFANT ALIMENT now known.*

HOSPITAL REPORTS.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Purpura Hemorrhagica.

This is the man with pleuro-pneumonia who was before the class on November 3d (see page 402), and was at that time suffering from pretty high fever. Since then the case has not progressed at all favorably, as his present condition and the history shows.

History.—November 10. Since the last record the patient's temperature has at no time fallen below 102°, nor has it risen above 103°. The heart has been regular, and the pulse for the past week has ranged from 80 to 100 per minute. The physical examination shows anteriorly slight expansion of the right lung at the apex, but a

want of expansibility on both sides at the base. At the left apex the vesicular murmur is loud and prolonged; over the right apex is heard a blowing sound during inspiration and expiration, and the voice sounds are muffled. Posteriorly over the right side there is dullness on percussion, extending from the spine of the scapula above to the base of the lung below. *Ægophony* is obtained at the inferior angle of the scapula. Patient was aspirated, and a quantity of turbid serum containing some leucocytes withdrawn. Brandy and quinine were administered.

December 6. Since the last record patient has been doing very well.

December 14. One week ago patient began bleeding at the nose, and epistaxis from the right nostril has continued ever since. In order to stop it, iced lint was put into the nostril; but it was not successful. Then the posterior nares and the anterior nasal passages were plugged; but without producing any beneficial effect, for the blood oozed out along the sides of the plugs, and it showed no tendency to coagulate.

On the third day of the hemorrhage, the right half of the nose became greatly distended and swollen. Ergot was administered to check the bleeding, but without effect. Then gallic acid was tried, and large doses of morphia were given, but to no purpose. He had lost about twenty ounces of blood during the past week. Yesterday it was noticed that his face became purplish in places, and small patches formed upon the cheeks and under the eyes. This morning similar hemorrhagic spots of a purple hue were found scattered over the thighs. His nose and face are so swollen that he cannot open his eyes. The patient now lies in a semi-unconscious condition, and evidently very much enfeebled from exhaustion, and he takes no notice of what is going on around him. His face is of a dark hue, and much disfigured, and is spotted with purple hemorrhagic patches scattered about, but especially under the eyes and on the cheeks. The right side of the nose is much swollen, and from the nostril projects a large plug covered with blood. He breathes through the mouth, and his breath has a very offensive odor. Hemorrhagic spots are to be seen in small streaks and patches just beneath the epidermis upon both thighs.

Gentlemen, you remember this man as a patient with pleuro-pneumonia, whom you saw convalescent in the wards some time ago. Eight days ago he began to bleed from one nostril, and all the efforts to check it which have been made since have been unsuccessful. The bleeding has been confined to the nostril for the most part, so far as we know, until within the last three days, when, as I had expected, he developed cutaneous hemorrhages, the blood collecting just under the epidermis, in some instances producing blood blisters, and in others indelible stains upon the face and limbs, and, I presume, on the back more freely than anywhere else.

The case is one of purpura, and of that variety called purpura hemorrhagica. Purpura is a term often applied to a simple cutaneous hemorrhage, but purpura hemorrhagica is only applied to those cases where the hemorrhage is not only upon the cutaneous integument, but also upon the mucous integument anywhere. It may be from the mu-

cous membrane lining the gastro-intestinal tract, or from that of the bronchial or genito-urinary tract, as from the vagina, uterus or bladder. There is no part of the tegumentary structure which is free from these hemorrhages. You will see cases of purpura hemorrhagica under various conditions, but much more frequently where you have an opportunity to see many cases of scorbutus.

Twenty-five years ago, when I was on duty in the Marine Hospital, sailors used often to come in with scorbutus, and some of these would then develop a purpura hemorrhagica. But this condition may also arise under other circumstances. You may have it during the course of cerebro-spinal diseases, and this, too, in patients who give no venereal history, and who are not of intemperate habits. And it sometimes occurs in connection with splenic leucæmia, and in other dyscrasic conditions, in which there is first a deterioration in the quality of the blood, and then a degeneration of the walls of the blood-vessels, and following this, an escape of blood into the surrounding tissues. This is a very different malady from that milder form of purpura, which is sometimes seen as a generalized eruption upon the skin. This milder variety is often found in persons who are apparently enjoying good health, and especially in those with a gouty or rheumatic habit, in whom, however, there appears to be a good condition of nutrition. But in such cases as this, from some unknown cause, we have a change in the constituents of the blood, and a deterioration in the walls of the blood-vessels, which allows the blood to escape into the surrounding textures. It is not important, however, that we should find these visceral hemorrhages into the stomach, lungs, liver, spleen, or kidneys, or into the pleural cavities, or possibly, in the meninges of the brain, in order to establish the diagnosis. In this condition the ordinary hæmostatics appear to do little or no good. Ergot and gallic acid have been tried here, but these have not acted so as to give relief, and the applications which have been made to the nostrils have also failed.

It has been said that this kind of hemorrhage is more readily arrested by the terebinthine applications. For example, it is said that a hæmoptysis depending upon a hemorrhagic dyscrasia is most satisfactorily treated by preparations of turpentine. I have used these to some extent, but I cannot say that my success with them has justified this statement. It has become common, however, to administer turpentine in cases of hæmoptysis, and it is thought by some to be most efficient where it is dependent upon a hemorrhagic dyscrasia, and not upon any local pulmonary lesion.

It is to be noted that in this patient the temperature has kept up. It went up the day the hemorrhage began, and it has since ranged from 103° to 103.8° and at the present time it is 103°. The fever under these circumstances may be explained as arising from the absorption of the elements of decomposing blood, or possibly hemorrhages into certain of the viscera are there acting as foci of infection, causing thus a septicæmia which is manifested by this continued rise of temperature. I do not see any other reasonable explanation of this high degree of fever.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, March 22, 1883. The President, Dr. Tyson, in the chair.

Dr. J. P. Crozer Griffith exhibited a case of

Chondroma of the Skull.

The patient, aged twenty-nine, had been admitted to the Presbyterian Hospital, Philadelphia, June 1st. He was and had been suffering from persistent and very severe frontal headache, and held his head thrown back upon his shoulders to the farthest extent. Examination revealed a tumor the size of a walnut upon the anterior portion of the vault of the skull. This had been recognized by the patient for from one and a half to three and a half months. Just how long was uncertain, as his headaches were very much cerebrous. He had suffered from headache for twelve years. Ophthalmoscopic examination revealed double choked discs.

While in the house the tumor grew with great rapidity and a new growth sprang up beside it. The larger one became soft and tender in spots. The patient became delirious, but coma and paralysis developed only three days before death, nineteen days after admission. The post-mortem examination revealed a large tumor upon the anterior portion of the vault, consisting of a soft red mass, but full of bone spicules; and to the right, and connected with it, a smaller dense hard white growth. Apparently distinct capsules enclosed and separated the two. The periosteum covered both tumors. The entire growth was irregularly oval, four and a half inches long by four to five broad, and with one and a half inches for its greatest thickness. Removal of the calvarium showed that the greater part of the tumor was internal. Here it was divided into three lobules, of which two resembled the larger tumor in structure, while the third was more like the smaller external growth. The dura mater covered the internal projection. At points it was attached to the brain, and bone spicules penetrated into the brain substance. The length of the entire internal growth was four and one half inches, width four inches, and the greatest depression upon the brain, two inches.

The tables of the skull within the tumor were destroyed, and the bone around the edge eroded for some distance. The brain structure did not appear to be altered. Microscopic examination showed it to be a reticular chondroma with a large amount of imperfectly fibrillated, and rather translucent connective tissue forming small meshes in which were cells; seven embryonic, but very many cartilage cells. The bone spicules were evidently newly formed, and the older tumor had evidently undergone an ossifying metamorphosis, and then had become vascularized, forming a soft mass in which the spicules were imbedded. Clinically the case was of interest from the existence of so great a depression of the brain, with so few signs of disturbance of its functions.

Dr. Wetherell asked what was the condition of the lymphatic system; were the glands enlarged?

Dr. Griffith replied that only the post-cervical were affected.

Dr. Formad had examined the sections about a year ago; it is true, as he says, the predominant cells are those which resemble those of fibro-cartilage. There were, however, many young cells, cells like giant-cells, but the majority of the sections had more the appearance of fibro-cartilage. The conclusion to which Drs. Tyson and Formad came at the time was that it was one of the varieties of chondroma. As the specimen appears now, it is too soft for chondroma, but seems rather to be a chondro-sarcoma. To this would point the rapid growth and age of the patient. It is certainly not gummatous.

Case of Metastatic Pneumonia following Pistol-shot Wound of Temporal Bone.

Presented by Dr. H. M. Fisher.

The patient, H. G., æt. 26, from whom the specimens I present to-night were taken, was admitted to Dr. Levis's wards at the Pennsylvania Hospital, October 31, 1882, suffering from a pistol shot wound of the right ear. The following clinical notes of the case were presented by Dr. J. H. Wills, resident surgeon to the Hospital:

Examination of the wound with the Nélaton probe showed that the ball had passed through the posterior wall of the external auditory canal, and was firmly embedded in bone about one inch from its point of entrance.

The seat of the ball was distinctly located by the marking of the lead on the porcelain of the Nélaton probe.

A prolonged effort to extract the ball was deemed inadvisable, on account of its close proximity to the lateral sinus. On account of the inflammatory œdema of the tissues around the wound, poultices were applied. Ptosis of the right lid, and slight depression of the right corner of the mouth, were noticed.

The patient remained in the hospital four weeks, during which time his general health appeared fairly good. He was permitted to go out on a pass, returned the following day with well-marked pleuro-pneumonia, and died ten days later.

The autopsy showed that the ball had penetrated the tympanic cavity and passed into the jugular fossa, where it was found embedded. There was marked periostitis in the neighborhood of the wound, but no inflammation of the walls of the lateral sinus, nor of the internal jugular vein, was noticed.

I am inclined to believe that the infarcts found in the lungs and pleura owed their origin to numerous small thrombi that had been formed in the diploë of the petrous portion of the temporal bone; the venules of the diploë having become plugged as a result of the periosteal inflammation. These thrombi becoming loosened in consequence of increased blood-pressure, were washed out into some one of the adjacent sinuses, and so into the pulmonary venous circulation. The case is, I think, an interesting one, as showing the danger attendant upon such injuries to the temporal bone, apart from any incidental injury to the brain or its membranes.

Sections of the heart, liver, spleen, and kidneys showed marked amyloid infiltration of these organs. Whether such marked changes could be induced in all these organs in the short period

that elapsed from the receipt of the injury to the date of the patient's death, is a question I would leave to other members of the Society to decide. At any rate, so far as I could ascertain, no previous history of suppuration was elicited from the patient during the time of his sojourn in the hospital.

Appended are the notes of the microscopical examination of the different organs:

Lungs.—Vessels everywhere greatly dilated and present numerous infarctions; the alveolar capillaries are also greatly distended, and their endothelium is swollen. Inter-alveolar spaces packed with lymphoid cells and embryonic connective tissue cells. The alveoli contain accumulations of epithelioid highly pigmented cells. These cells are generally found associated with exudation corpuscles in a delicate reticulum. These catarrhal intra-alveolar accumulations show in places a tendency to become organized.

The *pleura* is greatly thickened, its vessels dilated and infarcted.

Heart.—Muscular fibres show commencing fatty degeneration, and there is marked amyloid infiltration of the walls of its smaller nutrient vessels.

Liver.—Cell nuclei alone take carmine staining. Islands of liver-cells found in a translucent nearly homogeneous basement tissue. Evident amyloid infiltration of the walls of the finer hepatic arteries and biliary ducts.

Kidney.—The Malpighian corpuscles show stiffened capillary loops and little shrinkage from the action of the alcohol. The lumina of the arterioles are patulous.

Homogeneous translucent spaces are seen between the smooth muscular fibres of these vessels.

Spleen.—The lymphoid corpuscles of the pulp appeared to me to present an unduly homogeneous translucent appearance. The smaller vessels show distinct amyloid infiltration of their walls. The Malpighian bodies also show a notable infiltration, having in some cases been converted into amorphous masses, which are semi-transparent, and show interspersed among them a few connective tissue nuclei.

Case of Erysipelas Neonatorum.

Presented by Dr. H. M. Fisher.

Was called on March 3d, to see a colored infant one week old.

The child was said to have presented no sign of indisposition until the day previous to my visit, when it suddenly became much agitated, refused to nurse, and was found to have difficulty in micturition. The tissues of the scrotum and penis were found to be swollen, and in a few hours a faint erysipelatous blush was found pervading their surface.

When first seen the child was apparently moribund. I could detect no radial pulse, its lips were blue, its extremities cold, and it was in a semi-comatose condition. In the hasty examination I made in the small, badly-lighted attic in which I found the child, I observed but did not attach due importance to the erysipelatous blush I found extending from the scrotum to the lower part of the abdomen. From the history furnished me, and from the cedematous infiltration of the legs, thighs and eyelids, as well as of the scrotum and penis, I was inclined to look upon the case as

one of primary acute nephritis, with secondary erysipelatosus involvement of the oedematous tissues.

With this view of the case, I ordered that the child should at once be placed in a hot bath, and after the bath, applied flannels wrung out in hot infusion of digitalis to the patient's loins, and administered a small hypodermic of pilocarpine. Marked temporary improvement followed this treatment, the child emerged for a short time from its semi-comatose condition, cried lustily, and urinated and sweated freely, and marked reduction of the oedema was also noticed.

The improvement was, however, of short duration; the child soon relapsed into its former apathetic condition, and death occurred at 11 p. m.

The autopsy, made by Dr. McIlvaine, resident surgeon, eighteen hours after death, revealed rigor mortis pretty well established.

Oedema of the tissues of the lower extremities, scrotum, and penis, was noticed. There was a livid discoloration of the skin of the anterior inner aspects of both thighs, and slight sloughing of the skin of the lower part of the scrotum. The bladder contained about half an ounce of light yellow opaque urine. The urine obtained by tapping the bladder post-mortem showed, on examination, an apparent volume of albumen equal to about one-eighth of the column of urine in the test tube. Microscopically, blood and pus

corpuscles were found in abundance, and a few highly granular tube casts.

The kidneys were somewhat congested and lobulated, but their capsule was not adherent, and they did not, at least to the naked eye, present any other evidence of disease.

The liver weighed six ounces, and was highly congested.

The spleen weighed one and a half ounces, and was likewise congested and its surface mottled.

The lungs were pretty evenly congested throughout, but were everywhere crepitant, and floated on water.

The heart weighed two ounces, and presented on the whole a healthy appearance, but its posterior mitral cusp appeared somewhat thickened.

The post-mortem appearances leave, I think, but little doubt that the disease was peripheral in its origin, or, in other words, that the erysipelas was the starting-point of it. Probably some comparatively trifling cause, such as a slight abrasion of the scrotum, sufficed under the very unfavorable sanitary conditions in which the little patient was placed, to light up the train of the disease, with all its complications.

The progress of the disease seems in this particular case to have been unusually rapid. If the mother's statements can be trusted, only thirty-six hours elapsed from its first onset until the fatal termination.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Spleen in Syphilis.

The *London Medical Record*, February 15, 1883, tells us that Dr. Haslund, of Copenhagen, begins a paper on this subject (*Hosp. Tidende*, Nos. 2 and 3, 1882; and *Viertelj. für Derm. und Syph.*, Heft 2, 1882), with some remarks on the difficulty of determining the changes of the spleen in syphilis; firstly, because it is an organ which during life is only imperfectly accessible to physical examination; secondly, because its function is but little known; and, thirdly, because syphilis, when it does cause death, is generally so mixed up with other pathological conditions, that it becomes a matter of difficulty in any given case to decide whether the change is really due to the syphilitic dyscrasia or to some accidental complication. At the bedside a swollen spleen can sometimes be made out, but, in the author's opinion, only in the early stage of syphilis, and in cases where the prodromata are so severe that they resemble the symptoms of typhoid fever. In such cases, Dr. Haslund has twice made out an increased area of splenic dulness, but this speedily disappeared as soon as the febrile symptoms had departed. Thus the author does not accept the views of Jullien, Bäumler, Weil, and Wewer, who think splenic en-

largement a rather common occurrence. It is more frequently the case that a spleen tumor in the early stages of syphilis turns out after death to be due to amyloid degeneration. This change, however, is not due to the syphilis itself.

In order to form an independent opinion on syphilitic affections of the spleen, Dr. Haslund examined the *post mortem* records of the Communal Hospital of Copenhagen for a period of fifteen years (1866-80). Among these he found 154 cases of children who died with inherited syphilis. In ninety-six the spleen was healthy. In the remaining fifty-eight cases the spleen was diseased, the change being due to hyperplasia in fifty-five; in fourteen of these the consistence of the tissue was normal, in thirty-one the organ was harder, and in ten softer than natural. Further, one case of infarct was noted, one of fibrinous deposit on the serous surface, and one in which there were thickening of the capsule adhesions. In none of these three is there mention of alteration in size or consistence. Among the fifty-five cases of hyperplasia, fibrinous deposits on the surface of the spleen were noticed nineteen times, scattered patches of thickening of the capsule four times, and adhesions to neighboring parts once. Finally, in three cases there were miliary tubercles in the spleen, associated with tuberculosis of other organs. As regards the significance of these changes,

the author is of opinion that the simple hyperplasia must be considered to be in direct relation with the general disturbance of nutrition caused by syphilis; but whether it be a cause or a consequence of the cachexia must remain doubtful until the functions of the spleen are better understood. The other changes noted are considered to be not directly due to syphilis. Among the 154 cases there was not one of amyloid degeneration, and in only one were gummata mentioned in the report.

The author also examined the *post mortem* records of forty-four adults who died during the course syphilis in the same department of the hospital during the same series of years. In three of these there was amyloid degeneration of the spleen. This change, Dr. Haslund thinks, is always dependent on chronic suppuration either in the superficial tissues, in the bones, or in the internal organs. Of the three cases just mentioned, there was old necrosis of the scapula and clavicle in one, ulcerated gummata of the skin in another, and suppurative pyelonephritis with calculi in the pelvis of the kidney and left ureter in the third. Among the forty-four cases there was no instance of gumma. In ten the spleen was healthy; in twenty-seven there was more or less hyperplasia, the organ being softer than natural in eleven, and firmer than natural in sixteen; scattered thickenings of the capsule were noted in two cases, and adhesions to the surrounding parts in four cases.

Prolonged Antiseptic Baths.

From the *Med. Times and Gaz.*, March 31, 1883, we learn that in a recent *thèse* by Dr. Jannin he gives an account of the antiseptic baths first introduced for the treatment of surgical affections by Prof. Verneuil in 1870. Their application would be difficult for the lower extremities, but they are easily employed for any wound of the hand, arm, or elbow. The antiseptic solution, consisting of from 1 to 2 per cent. of carbolic acid, is employed tepid for about two hours at a time, and repeated two or three times a day—the parts being covered in the intervals with compresses wetted with the water of the bath. The writer concludes from his cases that the bath often renders immenseservice, and that in circumstances under which unfavorable prognosis has usually been drawn. That its employment in most cases suffices to prevent traumatic fever, and to cause the disappearance of painful symptoms. That when symptoms of septicemia are present, we can often arrest them, and cure the patient, and preserve the functions of the limb. In cases of bites from horses, and in contused wounds accompanied by much detachment and crushing, if the parts can be easily submerged, the prognosis, which is generally so bad, will be greatly improved, the patient in a few days becoming sheltered from accidents which so often prove fatal. In gunshot wounds, also, Prof. Verneuil has obtained several proofs of the great utility of the baths.

Injurious Effects on Health of Aniline Dyes.

A subscriber writes to the *Lancet*, March 3, 1883, as follows, giving some startling and valuable information:

"Speaking to a German gentleman recently, I was informed that an agitation was on foot in Germany having for its object the suppression or limitation of the use of aniline dyes in the manufacture of articles of clothing. These dyes have been found to be highly prejudicial and even dangerous in some recent remarkable instances, and strong feeling in opposition to their use has been a set up in certain quarters, which is likely to take the form of what we should call Parliamentary action.

"I should like to invite your powerful influence to raise a discussion on the subject in this country, where the use of these dyes is becoming so universal. My impression is, although I advance it with all humility, that a great deal of impaired health and unaccountable ailment may be traced to the use of clothing, especially underclothing, into the manufacture of which aniline dyes and their ingredients largely enter. Much was said some time ago about arsenical wall-papers and their prejudicial consequences; and seeing that aniline dyes are "fixed" with the same fatal poison, how much more serious must be the effect of a garment upon the wearer whose body is all day long in contact with its subtle and deleterious influence."

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—An interesting article on otitis media purulenta, by Dr. Dudley S. Reynolds, of Louisville, Ky., has appeared in the form of a neat reprint.

—The details of two typical cases of aphasia are given by Dr. Philip Zenner, of Cincinnati, in recent reprint from the *Lancet*, of that city.

BOOK NOTICES.

Lectures on Orthopedic Surgery and Diseases of the Joints. By Lewis A. Sayre, M. D., etc. Second edition, New York, D. Appleton & Co., 1 vol., 8vo. cloth, pp. 569.

This excellent treatise appears in this edition almost entirely rewritten and greatly enlarged. The illustrations are extended to a total of 324, one of them colored, facing the title, most of the others photo-electrotypes. Various new and improved methods of treatment are described, especially on the subjects of spondylitis and lateral curvature.

There is no higher authority on deformities and chronic diseases of joints than Dr. Sayre among living surgeons. His words contain the results of almost unequalled observations, and we doubt not this treatise will be received as the most complete expression of our knowledge of this branch of science for a long time to come.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

ABDOMINAL PULSATION.

Patients, particularly women, somewhat advanced in years, seemingly in good health, will frequently complain of an annoying beating, throbbing or pulsating in the abdomen.

This condition has sometimes given rise to a suspicion of aneurism of the aorta, but careful examination has failed to substantiate the suspicion.

Dr. Alfred Wiltshire has given considerable attention to this annoying symptom, and gives some valuable information on the subject in the *Medical Press*, April 11, 1883.

As a rule, the chief complaint is of an incessant beating in the abdomen, which becomes troublesome because of its persistence. Some patients complain that the beating shakes them so that they cannot sleep; others become alarmed and restless at the unwonted commotion in their bellies.

When asked to indicate the seat of their trouble, they usually point to a spot in the centre of the abdomen, a little above the umbilicus, sometimes higher, rarely lower.

When we have decided that aneurism does not exist, we must look carefully to the condition of the vascular system, since incompetence of the aortic valves permits regurgitation of blood backwards into the heart; the arterial system gets an impulse, often of exaggerated character, from ventricular hypertrophy, which fails so quickly as to produce a sense of back-thrust from the collapsing of the unsustained current, the vessels being inadequately filled. This condition may unaided excite the worst form of abdominal pulsation, but it is intensified by atheroma and poor blood. A kind of hammer-pulse is produced, and in thin people, whose abdomens are shallow, the violent beating causes distress.

A combination of aortic valvular incompetence, with the secondary cardiac mischief sooner or later ensuing (hypertrophy and dilatation), rigidity of the walls of the vessels, and impoverishment of blood, may produce the gravest form of morbid abdominal pulsation. Inquiry should therefore be made into the integrity of these parts. True

aneurisms are rare in women; and even the "fusiform dilatation" so often assumed to exist is rarely found *post-mortem*. Degenerative changes, however, may be observed.

The treatment must depend, of course, upon the cause, but clinical experience justifies the broad statement that in the majority of ordinary cases a vascular sedative, such as potassium iodide, is most efficacious. This applies equally to neurosal as well as aneurismal cases. But no case should be treated empirically.

Dyspeptic symptoms should never be neglected, for a distended stomach may intensify the trouble. Bismuth, charcoal, and soda are therefore useful. Aperients are of considerable importance, but they should be *laxatives* rather than purges, *e. g.*, decoction of aloes, or rhubarb, or magnesia, rather than salts. An excellent combination for many cases is R Potassii iodidi, gr. v. or x. in dec. aloes co. ʒj. bis die. Belladonna often forms a valuable addition to internal treatment; while a full-sized belladonna plaster over the seat of beating helps to soothe and calm the patient. Digitalis proves useful in certain cases.

In vascular disturbance due to renal inadequacy the kidneys demand attention, and the adjuncts of aperients and sudorifics should not be forgotten. Agents that influence arterial tension may here prove serviceable, such as amyl-nitrite, nitro-glycerine, bromides, etc.

But the chief agent in relieving abdominal pulsation is iodide of potassium. Its great value in arterial disorders, particularly aneurism, has been ably shown by Dr. Balfour; and my experience of its action in most cases of uncomplicated abdominal pulsation warrants the holding of a high opinion of its merits. The dose should not be less than five grains to begin with, and double this, or more, may occasionally be requisite. It is well to combine with it a little carbonate of ammonia, or potash if the urine be lithatic. It goes well with decoction of aloes when the latter is indicated. Should coryza be complained of, small doses of tincture of opium may be added when not otherwise contra-indicated.

Of the bromides, those of sodium, lithium, and

ammonium are somewhat less depressing than that of potassium, but it is not often that large doses are called for.

Digitalis may be useful in cases of cardiac incompetence, and when symptoms of renal disorder are present.

FILARIAL DISEASE.

Dr. Manson has recently made some interesting researches in Filarial disease, which he contributes to the *China Imperial Customs Gazette*.

The statement that *Filaria* are found in great numbers in the blood of an infected individual during the night, but are absent during the day, has been now substantiated by numerous observations.

On puncturing a gland in the groin, in a case of lymphatic œdema of the legs, Dr. Manson found in the lymph thus obtained not only the usual embryo *filaria sanguinis hominis*, as seen in the lymph and blood, but ova of the parasite containing active and perfect embryos. Since the parent *filaria* is not oviparous, how was the presence of the ova in this case to be accounted for? It was long before he succeeded in finding a similar case. But at last he was able to repeat the observation in a case of lymph-scrotum. He pricked a vesicle, and found *filariæ* in the fluid. The following day, when the lymph which had been drawn the previous day was again examined, *filariæ* were again to be seen. The feeble coagulum was now broken up by stirring. It rapidly disappeared, the small quantity of red deposit and some white cloudy flocculi subsiding. In this sediment were many embryos, and in nearly every slide ova with active embryos struggling vigorously to stretch through the chorionic envelopes.

Here, then, are two cases in which the ova of the parasite are found in the lymphatics; and, as Dr. Manson remarks, the parent *filaria*, like other animals, is liable to miscarry. This accident, he states, is fraught with danger, and is in fact the cause of the elephantoid diseases, and the key to their intimate pathology. Whilst the out-stretched embryo is only about $\frac{1}{3000}$ of an inch

in diameter, the ovum measures $\frac{7}{30}$ th $\times$ $\frac{1}{30}$ th, and is much too large to pass the glands. The embryo rolled up in its envelope cannot aid itself; it becomes, in fact, an embolus. The gland or glands directly connected with the lymphatic in which the aborting female is lodged, are thoroughly obstructed. An anastomosis for a time will aid the passage of lymph, but the anastomosing vessels will carry the embolic ova as well as the lymph. The corresponding glands will then in their turn be invaded, and so on, until the entire lymphatic system, connected directly or indirectly with the vessel in which the parent worm is lodged, becomes obstructed. Dr. Manson has examined lymph from the scrotum, the glands, and from the urine, in two hundred cases; yet, in this limited number of observations, evidence of premature birth of ova was obtained twice. Therefore, the accident cannot be of very rare occurrence; although, to have examined the lymph at the proper time, and in a suitable case, must be regarded as a fortunate circumstance not often to be encountered.

The novelty of the theory, and the apparent strangeness of the facts, says the *British Medical Journal*, naturally suggest a certain degree of caution before the explanation can be regarded as definitely established. But it must be remembered that the metamorphosis of the filaria in the mosquito, the phenomenon of filarial periodicity, and other discoveries made by Dr. Manson in connection with this subject, have all now been confirmed by many independent observers; and we can have little doubt that this last, the explanation of the causes of elephantoid disease by plugging of lymphatics by abortive ova, will also in time receive similar confirmation.

NOTES AND COMMENTS.

Hot Water Retrojection in Gonorrhœa.

This method of treatment is highly recommended by Dr. H. Holbrook Curtis in the *Med. Record*, April 21, 1883. An ordinary wooden arm-chair is half-mooned in the front of the seat to admit a tall cuspidor. A pulley is rigged on the ceiling by means of which a tin pail, with a

lamp beneath, is elevated. A rubber tube, provided with a stop-cock and connection leads from the pail, and at any time may be fitted to a No. 8 English flexible catheter. When the water reaches a temperature of say 120° , the catheter is vaselined and introduced to within an inch of the prostate, connected with the tubing, and the pail elevated to such a height that the flow is brisk. The lamp under the pail will keep the temperature slowly increasing. When the water becomes uncomfortably hot, the lamp may be extinguished. After some time a syringeful of the following injection is thrown in, and the catheter withdrawn:

R. Acidi tannici,	āā.	℥ij.
Iodoformi,		℥j.
Glycerinæ,		℥ij.
Aquæ,		℥ij.

This should be repeated twice daily. Internally he uses compressed tablets of five grains of bicarbonate of soda, ten daily. He has repeatedly passed as much as ten quarts of water from behind forwards in this way. From a careful study of more than forty cases, he claims that this treatment will shorten the duration of the disease by at least two weeks, that there is absence of chordee and pain in urinating, and that stricture is improbable.

Femoral Hernia.—Rupture of Coverings.

Dr. Bernard Pitts records in the *Lancet*, April 7, 1883, the case of a woman aged 46, who had had a right femoral hernia for twenty years. She had been once operated upon. One evening upon sneezing, the skin over the tumor, near to, but not in the line of the cicatrix, gave way, and a foot of intestine escaped. She was brought to the hospital three hours later on a cold, frosty night. The exposed intestine was congested, dirty, bruised and cold. Taxis failing, the wound in the skin was enlarged, the crural ring was nicked, and by manipulation the bowel was returned. The thickened sac was dissected out and removed, drainage for peritoneal cavity provided, and the edge of the sac brought together by very stout catgut, the edges of the wound by silk sutures, and carbolic gauze used as a dressing. The patient did well.

Digital Divulsion of the Pylorus.

This new operation, which seems to promise much, has been performed four times, twice successfully, and once so recently that no conclusion can be formed, by Prof. Pietro Loreta, of Bologna, Italy. Dr. Robert P. Harris gives a report of the operation, as received from Loreta, in the *Medical News*, April 21, 1883. It is recommended in

stenosis of the pylorus as a result of chronic gastric ulcer, but it is not supposed to be of any use when the stenosis is the result of carcinoma. The operation is performed as follows: When the stomach was exposed an incision was made into it, between and at equal distances from its two curvatures, commencing $1\frac{1}{4}$ inches from the pylorus and extending $2\frac{3}{8}$ inches in length. By careful rotation, the index finger of one hand was inserted through the aortic valve, to be followed by the other, when, back to back, the stricture was widely stretched without laceration. The serous surfaces of the stomach wound are brought into apposition by the continuous suture of Gely, which throws up a long ridge on the inside of the stomach; any water pressure shuts the lips of this ridge tighter together, and no gastric juice or liquid food can escape into the peritoneal cavity.

Did Syphilis Exist in America before the Discovery by Columbus?

In refutation of the affirmative, which has been asserted by some, Dr. William F. Whitney (*Boston Med. and Surg. Jour.*, April 19, 1883), concludes that the evidence presented thus far does not as yet clearly prove the existence of syphilis in this country previous to the landing of the Spaniards. The conclusive proof is still to be furnished by an extensively and symmetrically diseased skeleton, or by a skull presenting a typical case of caries sicca, as described by Virchow, in his Archives, vol. xv., p. 243. The exostosis noted on the bones of the legs of skeletons found in Indian burying-mounds and preserved in museums, might have been readily caused by violence and many other agencies than syphilis.

The Pathology of Diabetic Coma.

Dr. Stephen Mackenzie read a paper on this subject at the last meeting of the British Medical Association (*Brit. Med. Jour.*, April 7, 1883), in which he discusses the various ideas that have been advanced concerning the nature of the causative agent of diabetic coma, and concludes as follows: That no one of these theories is applicable to all cases of the coma of diabetes, though each explanation may fit particular cases. Though the evidence in favor of acetonæmia is at present quite inconclusive, yet, intoxication by some such poison, with a special affinity for the sympathetic system, developing in the blood or tissues, seems to him the most likely direction in which we will have to search for the cause of diabetic coma.

A Simple Instrument for removing Foreign Bodies from the Ear.

Dr. Louis B. Couch, of Nyack, N. Y., describes the following ingenious device in the *Med. Record*, April 21, 1883. He drills small holes into either end of a piece of eight-sided brass wire. Into one he solders a small twist drill, $\frac{1}{32}$ of an inch in diameter, and into the other a sharply cut screw $\frac{1}{25}$ of an inch in diameter. A hole is drilled into the foreign body, the drill is removed, the screw is inserted, and the article must come.

CORRESPONDENCE.

EDS. MED. AND SURG. REPORTER:—

In your issue of April 14th, page 417, is an article from Dr. I. H. McClellan, of Pittsburgh, commenting upon Dr. A. A. Smith of New York. Dr. McC. writes like a so-called homœopath. I think, according to the tenets of Hahnemann, that he does not know the principles of *his dogma*. I don't know what his practice is.

The first principle of Hahnemann is that the human family is affected with psora, which you and I know we have not.

The second, that like produces like. Who ever heard of tincture of aconite producing fever, or belladonna scarlet fever? There is a rash sometimes in the last, but that is not the essential of scarlet fever; etc., etc.

Third—comminution and trituration and dilution increases potency. There is no need to dilute on this, but Dr. McC. seems to think he has Dr. Smith on the hip because he uses *small doses*. Why! Dr. McC. ought to be appalled at the large doses of Dr. Smith. According to the third principle of homeopathy, I look upon him as anything but a beaming disciple. If we use small doses we use *appreciable doses*, not infinitesimal ones, according to the homeopathic manner—when the thirtieth dilution is considered awfully powerful, to say nothing of the gigantic proportions they obtain from the mere whiff over the mouth of an empty bottle which has held one of their potentized articles. X. Y. Z.

(Our correspondent, a distinguished physician, for satisfactory reasons does not desire his name made public.—EDS. REPORTER.)

Pyrogallic Acid in Eczema.

EDS. MED. AND SURG. REPORTER:—

In the April number of the *Compendium*, Dr. Jarisch is quoted as having seen "eczema marginatum cured by applying a 5 or 10 per cent. ointment of pyrogallic acid." For several years I have used R. pyrogallic acid and raw linseed oil, aa, in nearly all cases of this kind, and have seldom had occasion to change the medication or renew the prescription for the case, provided proper constitutional treatment was carried out as directed.

F. R. MILLARD, M. D.

San Diego, Cal. April 20, 1883.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

(Continued from page 535.)

THURSDAY AFTERNOON.

At the afternoon session the Committee on Nominations reported the following for the ensuing year :

For President, Henry H. Smith, of Philadelphia.

For Vice Presidents, Ellis Phillips, of New Haven; H. B. Vanvalza, of Clearfield; J. W. Kerr, of York; S. Schultz, Danville.

Permanent Secretary, Wm. B. Atkinson, of Philadelphia.

Recording Secretary, Morris S. French, of Philadelphia.

Corresponding Secretary, John G. Lee, of Philadelphia.

Treasurer, Benj. Lee, of Philadelphia.

The Medical Society of Pennsylvania to meet in Philadelphia.

On motion, this report was received and adopted, and the Committee on State Board of Health was continued.

After Dr. Moody's address in Obstetrics (see page 513).

The address on Hygiene was read by Dr. Henry Leffmann, of Philadelphia. It touched briefly upon the earlier notions of the causation of disease, and made passing allusion to the present popularity of the germ theory. The subject of disinfectants was then considered, the reader of the address expressing himself as in general opposed to the various disinfecting and germicide preparations now so extensively advertised. One in particular was mentioned, which consisted of nothing but charcoal and sulphur, and was sold at an exorbitant rate as an "ozone powder." The great importance of physicians endeavoring both by example and teaching, to eradicate the prevailing errors in regard to the effects of ordinary exposure, was dwelt upon at length, and accounts given by eminent writers on hygiene, etc., were cited to show that conditions of exposure which, according to common opinion, should have proved most injurious, were actually found to be beneficial. The lecturer took the ground that more harm was done by fear of exposure to "drafts" and to "night" air, than by actual exposure to these influences.

Dr. Samuel Ayres, of Pittsburgh, for several years first assistant physician to the hospital for the insane at Dixmont, Pa., read the next paper, entitled

OUR ASYLUMS AND OUR INSANE.

The more general agitation in our country of late years, of matters relating to the care of the insane and the management of asylums, has produced good results. It has led to examination into the methods of these institutions, and their manner of treatment, and to improvement in their system, through recommendations and enlightened legislation.

The New York Neurological Society took the initiative in this more recent alienistic movement, followed by the National Association for the Protection of the Insane and the Prevention of Insanity—the growth of which body has been re-

markable, and its influence in promoting the study of insanity and ameliorating the condition of the insane, widely felt.

The writer believes the lunacy problem is not yet fully solved, that there is need for improvement in many branches of the subject, and that fair and intelligent discussion of its different phases will admit more light and lead to needed reforms.

Reference is made to the increasing dissatisfaction with the management of asylums, and to the distrust in their efficiency as places of cure for the insane, and the admission is made that there is much ground for this want of confidence, owing to the peculiar administration of their affairs and the defects in their system.

Those defects relate to

1. Superintendents.

Though asylums may be palatially built, perfect in all their appointments, vigilantly inspected, with faithful boards of managers, yet if the superintendents be not humane and scientific physicians who give their *entire time* to the immediate medical interests of their patients, the above will amount to little, the percentage of cures will be reduced, and the chief end for which these institutions are erected—viz., the cure of the curable and the best care of the incurable—will be in a great measure defeated.

The chief medical officer of an asylum cannot be at the same time purveyor, farmer, florist, paymaster, clerk, steward, financier, lobbyist, etc., etc., and practicing alienist. It is utterly impossible, and yet it is daily attempted with lamentable failure.

It would often appear that the growth of cabbage and currant interests this officer more than morbid growths in the encephalon; that the location of a turnip or a potato patch interests him more than the localization of cerebral lesions; that he takes more pleasure in making his asylum a grand insane boarding-house, than a hospital for the study, treatment, and cure of mental diseases.

By thus endeavoring to perform so many duties, he becomes involved in endless details, his attention is diverted from the patients, and he finally loses, to a great extent, medical interest in them.

The remedy is simple. Let the physician-in-chief be a man of high medical attainments, qualified from special preparation in the treatment of insanity. Let him devote himself exclusively to the care and treatment of his patients, and have nothing to do with the farm, garden, and household affairs. These matters should be entrusted to proper officers, who shall report to executive boards.

2. Assistant Physicians.

When chairs upon nervous and mental diseases are established in our medical colleges, these officers will be somewhat prepared to enter intelligently upon their duties. In the meantime, they should receive from superintendents all possible instruction in the nature and treatment of the cases under charge. It occasionally happens that superintendents are not competent to scientifically instruct their assistants—in which event, if these also be indifferent physicians, we cry, Good Lord, deliver the patients!

The physician-in-chief, accompanied by his medical assistants, should visit the male and female departments on alternate days, and thus see all the inmates every two days, and direct their treatment.

There should be increased medical service in asylums, at least one assistant physician to one hundred patients; and where many recent and curable cases are received, this ratio should be much greater.

3. Consulting Medical Staffs.

Every asylum should have such a staff, consisting of five able physicians—two experienced in nervous and mental diseases, one a surgeon, one a general practitioner, and one agynecologist. And such a board should be *real*, and not merely nominal.

The alienists should visit the hospitals at least once a week, examine all recent cases, and consult fully upon their diagnosis and treatment with the resident staff. The other members need not pay regular visits, but be called in whenever cases are presented involving questions in their respective branches.

4. Asylum Therapeutics.

A routine prevails both in prescribing and dispensing medicines which would surprise the active general practitioner. The administration of appropriate drugs in certain forms and stages of insanity, is attended by effects as pronounced as in any other disease. Pathological processes let alone or carelessly attacked, generally leave their victims hopelessly insane.

The subject does not receive nearly the attention its importance demands.

5. Pathological Work.

Very little of it is attempted. It is a matter of profound regret that the vast quantity of valuable material for this study furnished in these institutions, is lost to science.

There is no reason why the work should not be undertaken even in a small way in every asylum. Its neglect results from the system in vogue, and the inexperience of superintendents in pathological investigation.

6. Gynecological Treatment.

It is often asked why this treatment is not conducted in all asylums, and very unsatisfactory answers are given to the question—such as do not become earnest and conscientious physicians.

Cases of insanity in women caused by disease of the reproductive organs are constantly to be found at asylums. And yet the subject receives little or no attention. Such neglect is culpable, well nigh criminal in superintendents. There are some obstacles, it is true, to this treatment, but they can be surmounted if it is resolved they must be.

7. Employment of the Insane

Is next dwelt upon, and the evils of idleness contrasted with the advantages of suitable occupation.

The matter is fortunately engaging the attention of our asylum alienists, and in a few of the institutions from 50 to 85 per cent. of the inmates are employed in one way or another.

8. Overcrowding

Is often carried to an alarming extent, as many as

five patients being packed for the night in a room 8x13, poorly ventilated. This evil increases the suffering, sickness, and death-rate of these unhappy beings, and prevents the recovery of many otherwise curable.

It should not be permitted by managers under any circumstances, notwithstanding the demand for more asylum accommodations.

9. Unjust Commitments.

Much has been said of late in the secular press about the incarceration of sane persons in asylums by interested relatives. But these rumors, when thoroughly investigated, are usually found to be emanations from the brains of unrestored ex-inmates. However, to prevent even its rare occurrence, the laws should be very stringent on this point, and the severest punishment visited on those who would conspire to this end. Moreover, asylum physicians should be required to give their opinion as to the sanity or insanity of all patients within one week after admission, and procure the prompt release of any one improperly held.

10. Prolonged Detention of the Cured.

From the failure of superintendents to give their undivided attention to the inmates, it occasionally happens that the restored are detained unnecessarily long; and that others, through the solicitations of friends, are discharged before they ought to be.

11. Restraint.

The subject of mechanical restraint in the care of the insane has been freely discussed. The dungeons, shackles, and chains of the past have given place, in the march of civilization, to the asylums, cribs, and straight-jackets of the present; while these severe forms of restraint are fast yielding to the milder methods of management, suggested by science and humanity. The writer is not sure but in very rare cases, mild coercion might be employed with advantage; but since it is liable to be so badly abused, he advocates the entire abolition, as has been done in so many of the foreign asylums and in some of our own.

12. Cruelties.

The reports of cruelty inflicted upon the insane in asylums are, unfortunately, often true. These patients are frequently the victims of abusive treatment at the hands of heartless attendants. It is not argued that this practice can be wholly prevented, because kind and intelligent nurses can not always be obtained. But it can be much reduced, if mechanical restraint is discarded, and superintendents and assistants will constantly supervise their patients. The most abuse occurs, though, in the absence of superior officers. And to break this up, the writer advises resort to a detective system. A male and female detective in the guise of patient or nurse should be employed, who should shadow the suspected attendant. If he is found guilty of violence or brutality, he should be prosecuted for misdemeanor and punished to the full extent of the law. A mere discharge from service will not answer. In this way it is believed cruelty could be reduced to a minimum.

The second part of the paper is devoted to a

brief consideration of the non-asylum insane, and the importance of reducing the supply to the increasing insane population, which now numbers about one hundred thousand in the United States.

(a) *Prevention of insanity* and (b) its prompt cure when developed, will accomplish this most desirable end, and are the two vital practical questions of the day for all alienists.

The people should be taught how they may prevent the approach of insanity, and avert it when threatening. A due observance of the laws of physical health in relation to mental conditions should be impressed upon them through popular journals and manuals on the subject.

The importance of treating cases in the incipient stage is especially urged, when there is every chance of cure. And this may be undertaken at home with many advantages, if physicians will acquaint themselves with the methods of the plan. It is practicable, and has proved successful in the hands of the writer and of many others. If for valid reasons this cannot be conducted, prompt consignment to private hospitals or asylums is advised.

The Treasurer, Dr. Benjamin Lee, then read his report.

Treasurer's Report.

Balance May 11, 1882	\$1,965.68
Receipts during year	2,269.91
	\$4,235.59
Expenditures during year	1,871.75

Dr. Peter D. Keyser, of Philadelphia, read a paper entitled

"SOME OPHTHALMOLOGICAL OBSERVATIONS DURING TEN YEARS' SERVICE (1872-82) IN WILLS EYE HOSPITAL."

During which time he had attending his clinic 5,243 patients, classified as follows: Affections of the lids, 390; of the lachrymal apparatus, 164; muscular and nervous affections, 202; anomalies of refraction and accommodation, 913; diseases of the conjunctiva, 1,211; of the cornea and sclerotic, 1,146; of the iris, ciliary body and choroid, 454; of retina and optic nerve, 211; of the crystalline lens, 230; of the vitreous body, 57; of the eye-ball, orbit, etc., 165. The number of operations performed during the same period was 1,282, among which were 148 extractions of cataract, 36 decisions of soft cataract, with four suction by Bowman's pump; 164 iridectomies, 5 iridotomies, 11 Passavant's operation for posterior synechia, 1 Streatfield's for the same trouble, 92 tenotomies of recti muscles, 106 operations on the lachrymal apparatus, 200 operations on the lids, 87 enucleations of the eye-ball, 3 optico-ciliary section, 4 drainages after De Wecker, and 422 sundry operations on the cornea, conjunctiva, lids, etc. In the affections of the lids all the general forms of disease were more or less met with, and in the treatment of tarsal inflammation many cases were much benefited by De Wecker's method of the use of his pomade antiblepharitique, the odor of which, however, was so unpleasant that he (Dr. K.), with Mr. L. E. Sayre, pharmacist, of this city, made a new pomade, having the same

medical effect and of much more pleasant odor, as follows: Oleopalmitate of lead, 20 parts; almond oil, 10 parts; simple cerate, 5 parts; balsam peru, 1 part; liquid tar, $\frac{1}{2}$ part. In most, if not all, cases of this affection met with, anomalies of refraction were found, the correction of which was necessary to succeed in a permanent cure.

Descriptions of cases of entropion and ectropion are given. Epithelioma, when small, was benefited by topical use of powdered chlorate of potash.

In the treatment of conjunctivitis, weak solutions of astringents instilled frequently into the eye were found more efficient than stronger solutions used once or twice daily.

In purulent and gonorrhœal forms, reliance was placed upon frequent cleansing of the eye and alternate instillation of saturated solution of boric acid and a weak solution of nitrate of silver.

Membranous conjunctivitis was treated successfully by a collyrium of chlorate of potash, hot applications and quinine and iron internally.

Of the conjunctiva is given a description of a fatty tumor of very rare occurrence, also a case of multitudinous recurring warts, also a double dermoid tumor of the conjunctiva and cornea.

Of rare affections of the cornea, six cases of keratitis bullosa are described, also a case of phosphatic degeneration of the external layers of the cornea. A very large tumor of the cornea with figure and microscopic description.

Glaucoma was treated by iridectomy, eserine instillations and sclerotomy. After considerable experience, iridectomy was found the most reliable for permanent success. Of the uveal tract an interesting case of iritis with gelatinous exudation, is described in full.

Two interesting cases of melanotic sarcoma of the choroid, one with metastasis and death, are reported with figures and microscopical drawings.

Sympathetic ophthalmia, with the history of case in which recovery took place.

Detachment of the retina was treated by several methods of operation, including De Wecker's drainage, and also the use of pylocarpin internally and hypodermically, but without any great permanent success from either method.

Several interesting cases of removal of foreign body from the eye-ball are given.

The inheritance of congenital cataract is shown in a family, running successively through four generations.

The 148 cases of extraction of cataract are all described with the following result: as perfect success vn. to $\frac{20}{cc}$ 92 per cent. Total loss from

sloughing and inflammation 6 per cent. Occlusion of pupil from iritis, which might have been improved had operation been consented to, 2 per cent. The acuity of vn. obtained as follows:

$\frac{20}{xx}$	4 cases	$\frac{20}{xxx}$	12	$\frac{20}{xl}$	23	$\frac{20}{l}$	17	$\frac{20}{lx}$	3
$\frac{20}{lxx}$	22	$\frac{20}{c}$	43	$\frac{20}{cc}$	11	$\frac{10}{c}$	1.		

In the operations in the hospital, many different methods were tried, and fortunately with success, but after all, the preference was given to that of Von Graefe, with the incision of the cornea nearer to, if not in the corneal junction, instead

of as far back as recommended by him. In cases of sluggish iris and inflammatory dispositions, preliminary iridectomy was made some weeks previous to extraction. He describes a method and manner of opening the capsule which he finds lessens the danger of inflammation and necessity often of subsequent operations, and by which a large piece of the membrane in pupillary region is removed.

Two cases of fibro-myxoma of the optic nerve are quoted, as well as a cyst of the lachrymal gland successfully operated upon, and a polypus of the lower canaliculus extending out of the punctum.

Dr. Joseph Hearn, of Philadelphia, then read his paper on the "Cure of Rodent Ulcers," presenting two patients, who had been pronounced hopeless, but who, under Dr. Hearn's treatment, gave every indication of cure, and one patient, a lady, on whose face a rodent ulcer of five years' duration had been entirely cured.

Dr. Hearn said that cases treated early and promptly can be cured. These ulcers, which are called flat cancers, become malignant when not treated promptly. They usually begin with a hard nodule, or on a scar or wart, and not with an ulcer. Over this a crust forms, which leaves a depression, and this becomes an ulcer. The rodent ulcer is generally solitary, and generally comes about the face. The treatment is by caustic, knife, or both, the diseased tissues being entirely removed.

Dr. J. V. Shoemaker, of the Philadelphia Hospital for Skin Diseases, before reading his paper on the "Hair—Its Use and Care," introduced a patient from the hospital, whom he is now treating for lupoid growths, with success. The substance of Dr. Shoemaker's paper was as follows: "It requires both constitutional and local care to keep the hair in its normal healthy state. In the first place, that essential material, food, which is necessary to supply the waste and repair of all animal life, should be selected, given, or used, according to good judgment and experience. The nervous system, which is one of the most important portions of the human structure, and which controls circulation, secretion and nutrition, often by being impaired plays a prominent part in the production of baldness. The stiff hats, so extensively worn by men, produce more or less injury. Premature baldness most frequently first attacks that part of the head where pressure is made by the hat."

As regards the head-covering of women, the fashions have been for several years favorable to a proper form. The bonnet and hat have become quite small, and cover but little of the head. This beneficial condition, however, is in part counterbalanced by the weight of false curls, etc., with which women dress their heads. Ablution with soap and water should be performed once or twice a week at least, particularly to the head and beard, in order to keep open the hair tubes, so that they may take in oxygen, give out carbon, carry on their nutrition, and maintain the hairs in a fine polished and healthy condition.

It is injurious to both men and women to go into the surf having some wasting of the hair,

without properly protecting it; the sea water has not, as is often thought, a tonic action on the scalp; on the contrary, it often excites irritation and general thinning.

In conclusion, if the hair becomes altered in texture, or falls out gradually or suddenly, or changes in color, a disease of the hair, either locally or generally, has set in, and the hair, and perhaps the constitution, now needs, as in any other disease, the constant care of the physician.

Under the head of Unfinished Business, the report of the Committee on Schedule of Subjects for Medical Examinations reported. Some debate followed, Dr. S. D. Gross declaring the standard proposed too high. He saw no use in stuffing a young man with Greek and Latin and Mathematics, compulsorily, to make a doctor of him, although a certain amount of these things is necessary to enable him to understand the technicalities of the profession. He thought private pupils shamefully neglected in nearly all cases.

Drs. Andrews, Bishop, Donnelly, Wilson, and others, spoke in favor of, and Dr. Tyson against the report. A general discussion followed.

Dr. O. H. Allis, the chairman of the committee, explained that the standard proposed in the report of the committee is simply that laid down in a resolution by this association in 1878.

Dr. William Finley, of Altoona, said this association had appealed to the colleges in vain for thirty-six years to raise the standard of admission to the profession.

The report of the committee was then adopted.

Dr. S. D. Gross then offered a resolution, which was carried, that this society request all county medical societies in the State to take measures to provide instruction for nurses.

The Committee on Medical Education then made a long report through its chairman, Dr. R. L. Sibbett, of Carlisle, which, after debate, was adopted.

Dr. Henry Leffman presented some reports and the following amendment to the By-Laws, offered by the Philadelphia County Medical Society:

Resolved, That no documents be presented before the State Society that have not been read before a county society and been recommended by said county society.

The resolution, according to rule, will lay over for one year.

Drs. Eskridge and Keen having refused to serve on the committee to act on the resolutions of the Anti-Vivisection Society, Drs. H. C. Wood and S. Weir Mitchell were appointed in their stead.

Dr. C. Z. Weber introduced the resolutions of respect and the address by Dr. Hiram Corson, adopted by the Montgomery County Medical Society, upon the death of Dr. David Schrack.

On motion, the resolutions were adopted and ordered to be incorporated in the proceedings, by a standing vote.

In the evening, receptions were held at the residences of Drs. J. K. Weaver and Mary Stinson, and G. W. Rogers, esq., of Norristown.

FRIDAY MORNING.

After prayer by Rev. A. J. Weddell, The address on "Mental Disorders" was deliv-

ered by John Curwen, M. D., Superintendent of the State Hospital for the Insane, at Warren, Pa. In the course of his well-digested and interesting remarks, he said:

"The hereditary character of mental and nervous disorders and the necessity of careful regulation of the health of the mother during pregnancy, and the removal, as far as possible, of all causes of vexation and annoyance, to prevent as much as may be the influence on the child, and instances adduced where the health and mental integrity of the child were affected by causes acting on the system of the mother during pregnancy.

"It was urged on the profession to give more strict attention to the tracing out of the various histories of different cases so as to reach more certain conclusions as to the results of certain disorders and influences in the production of particular forms of disorder."

"The necessity of careful attention to the health of children, and the impropriety of placing them at an early age in school, was also insisted on so as to avoid that taxing of the mind and the interference with the bodily development so likely to arise from the confinement in school and inability to fix the mind on what was required to be learned. The first point to be aimed at was proper physical development.

"The training of the children should involve a thorough discipline in the education of the different faculties of the mind so that one class should not be educated at the expense of the other; that the states of feeling, including the passions and emotions, should be kept in subordination to the state of knowledge and the state of will. The tendency of the times is to give greater prominence by means of the books and other matters to the development of the passions and emotions, and on this account so many are unable to stand the wear and tear of life and fall victims to mental and nervous disorders, which could have been prevented by that attention to the proper regulation of these in connection with the development of the intellect and the will.

"The necessity of proper nutrition affording these elements most readily assimilated for the use of the different parts of the system, was also dwelt upon, and also the prime importance of an abundant sleep, not only in the early years, but throughout adult life.

"In school life it was insisted that what was taught should be well drilled in so that what is learned should be thoroughly learned, as it was better to know a little well, and so as to be of practical advantage in the duties of life, than to gain a large amount, so that in a short time it should be only a confused mixture in the mind and not of any practical benefit.

"Attention should also be given in education to the peculiar bent or aptitude of the scholar so that he shall not be compelled to give strict attention to what is distasteful, and not within his comprehension or above his capacity.

"Attention was also directed to the baneful influence of the use of tobacco on young men in the retardation of the proper growth and development of the mind, and its injurious influence on those who had been doing well, but were thrown back by its use.

"Reference was also made to the practice of

other habits consequent on the character of the books furnished so generally for the young."

Dr. J. T. Eskridge followed with a paper on "Diagnosis, Prognosis and Treatment of Mitral Constriction," which will appear in full in our next issue.

"LITHÆMIA"

was the title of a paper by Dr. James B. Walker.

This term, first used by Murchison, is applicable to what may be termed a diathesis in which there exists a tendency to the undue production of uric or lithic acid, in place of the more fully oxygenated nitrogenous debris, urea.

Being less soluble and less readily eliminated than urea, it goes the rounds of the circulation, gathering as it goes, until it is present in the blood in sufficient quantity to constitute it a toxic agent.

As a toxic agent it gives evidence of its presence most characteristically by its circulatory symptoms. Stimulating the muscles of the arterioles to hyper-activity, either directly or through the influence of the vaso-motor system, it retards the egress of blood from the arterial system, leading to hyper-distension of the same. This calls for increased force of the left ventricle in emptying itself, and, through both agencies, we have the most pathognomonic symptoms, viz., the *pulse of high arterial tension*.

Increased arterial recoil induces, so long as the aortic orifice remains apatulous in diastole, an *accentuation of the aortic second sound*.

Increased arterial tension induces *increased urination*.

These constitute the essential symptoms of lithæmia, but to them may be added those due to functional or organic disturbance of any organ of the body. Bronchitis, pneumonia, emphysema, nervous disturbances of mild or grave character, including local cramps, tingling of extremities, numbness, vertigo, diplopia, headache, tinnitus aurium, and even insanity; angina pectoris, from the general arteriole spasm is not uncommon.

To the functional disturbances of the circulation are added arterio-capillary fibrosis, first clearly described by Gull & Sutton, which may extend to development of the fibrous tissues of organs, inducing especially interstitial nephritis, whose characteristic symptoms are those of the accompanying lithæmia. Atheroma of aorta, or of more or less of the systemic arteries, is quite common of cases of long standing, and by the danger in aneurism, apoplexy, thrombosis, and embolism, constitutes a serious pathological result. Or the uric acid may tend to deposit and excite irritation in the feeble circulation about the joint structures, resulting in an attack of gout. Or to be excreted in excess of the power of the urine to hold in solution, when uric acid gravel will ensue.

The *diagnosis* of Lithæmia rests on the presence of four prominent symptoms; viz.:

1. Pulse of high arterial tension, *i. e.*, persistently, hard and cord-like.
2. Accentuation of aortic second sound.
3. Hypertrophy of left ventricle.
4. Increased urination.

Given these persistently, or temporarily, re-

curring from slight causes, and we have Lithæmia, whatever else we may find to co-exist.

The *prognosis* depends upon the period of the disease. It is necessary to take an inventory of the amount of diseased and healthy structures present in each case, in order to form a just estimate of the prognosis.

If treated early, when only functional disturbances have been engendered, it promises complete relief. If organic changes have resulted, we have to that extent a permanent clipping of the organism.

The *Treatment* consists in

1. *Lessening the amount of nitrogenized detritus.* This, by diminishing the amount of animal diet to a minimum, meats either eschewed altogether or given in small quantity; milk in quantity is the best animal diet; vegetables ad libitum.

2. *Bringing about as complete combustion of the essential nitrogenized detritus* as possible that the uric acid may be converted into urea. Exercise and fresh air are the best agents for this.

3. *Rendering more soluble and more readily excreted the uric acid, which remains unaltered.* Lithium and potassium form with uric acid its most soluble compounds. These may be given as citrate or acetates in sufficient quantity and for a long period without injurious effects.

4. *Antagonize by physiological antidotes the more violent and severe symptoms.* Bromides, perhaps, the most serviceable for the nervous symptoms. For angina pectoris amyl nitrite is the remedy par excellence, given either internally or by inhalation, securing prompt relief. But as it is but palliative, its results must be secured by the bromide and other potassium salts.

This for the lithæmia. For the complex symptoms likely to arise, appropriate treatment is needed. What I wish to render prominent is the importance of finding behind and beneath the mass of pathological debris the morbid agent, and of attacking this, whatever else we may do or leave undone. I desire also to give prominence to the assertion that in chronic Bright's disease without dropsy, in atheroma of the arteries with cardiac hypertrophy, in angina pectoris, in apoplexy, and a host of functional disturbances, if the symptoms of lithæmia be present, and they usually will be, this is the condition against which therapeutic measures are to be leveled.

Dr. Edward T. Bruen, Demonstrator of Clinical Medicine in the University of the Pennsylvania, read a paper entitled

"CLINICAL NOTES ON THE USE OF CONVALLARIA MAJALIS."

In the present state of our knowledge of the action of convallaria majalis we are obliged to accept the records of clinical experience, even if they have been based on comparatively a few cases. There is all the more interest centered in this drug since it has been made of late the subject of very conflicting testimony from the physiological laboratory on the one hand, and from the bedside observation of the clinician on the other.

In 1851, G. F. Waltz discovered in the Convallaria Majalis two active substances—Convallarin and Convallamarin. The first is crystalline, in-

soluble in water, and according to Dr. Marmé's experiments (Schmidt's Jahrbuch), when taken in doses of three or four grains, acts as a simple purgative. The glucoside Convallamarin is soluble in water, and is the principle to which the plant owes its action on the circulation.

A synopsis of the action of Convallaria upon the circulation establishes, according to Marmé, that it kills by direct action on the heart, and in moderate doses first slows, then quickens the pulse. Previous divisions of the vagi do not interfere with the development of these phenomena. These observations have been confirmed by other investigators,* their experiments showing that it slows the action of the heart and increases the blood pressure decidedly. If a toxic dose has been given, the heart's beats become very rapid and irregular, the arterial pressure still being much above the normal, finally the pressure begins to fall, the cardiac pulsations to grow more feeble, and death occurs through syncope. The pneumogastric nerves are weakened but never paralyzed, whilst the general nervous system is not affected.

Dr. Isaac Ott (*Archives of Med.*, Feb., 1883,) has found that the arrest of the heart is systolic, the heart muscle not being able to respond to the most powerful galvanic stimulation. From this testimony it would seem evident that convallamarin acts almost exclusively upon the heart and its contained ganglia; possibly also upon the vaso-motor system.

Diuresis and purging have followed its use in the lower animals, and the drug is stated to have been long used by the Russian peasantry for the relief of dropsy.

This brief synopsis includes the most important facts from the physiological laboratory.

The following conditions have been chosen as typical ones illustrating clinically the employment of convallaria:

Case I was seen in consultation with Dr. F. W. Robinson, of Philadelphia, on March 10. The patient, a lady about thirty-five years of age, previously very robust, had been taken ill with pneumonia on the afternoon of the 7th. The earliest symptoms were those of intense pulmonary congestion; the surface of the body being cyanotic, and dyspnoea very pronounced. The lower part of the upper lobe and the inferior lobe on the left side were involved, also the base of the right lung. The interesting feature of the case was the action of the heart. From the first, this was extremely irregular and very rapid, about 120 per minute. Appropriate treatment was carried out during the 7th, 8th, and 9th, including bleeding from the arm; digitalis in full doses; strychnia, $\frac{1}{30}$ of a grain four times daily. Subsequently, the free use of cardiac stimulants. The irregularity of heart, if possible, became more pronounced, so that on the 9th the digitalis was discontinued, and the fld. ext. of convallaria in 15-drop doses every two hours was substituted. Within thirty-six hours the action of the heart became nearly regular, and the pulse fell to 80. The patient was roused from a state of impending death, and for a time we entertained hopes of recovery. When the convallaria was first given,

* Prof. See (Bulletin de l'Acad. de Med. No. 27, 1882) and S. Isaacw, (Med. Schwabels Jahrb., 1883.)

the left ventricle was contracting vigorously through the effect of the digitalis previously used, but the gain had been solely in the direction of the increase in systolic muscular power. At the end of thirty-six hours after the use of the convallaria, the action of the ventricle having weakened, we combined the convallaria with the tr. digitalis with most satisfactory results so far as the cardiac action of these drugs was concerned; and the good effects persisted until the 16th, when the strength of the patient was exhausted and death ensued.

My first classification of conditions in which convallaria has been serviceable to me is:

(1) Those cases of acute disease of the lungs in which irregularity of the heart is a symptom. In these cases the action of the convallaria is helped by its combination with digitalis, the latter drug having a principal influence as a tonic to the cardiac muscle, the convallaria apparently exercising a principal influence upon the vagi, or at least it inhibits the cardiac rhythm.

(2) In organic valvular disease the convallaria is most useful in cases of mitral obstruction. In these the action of the heart is most apt to be irregular because the volume of blood returned to the left heart through the pulmonary circulation has not time enough to empty itself through the left auriculo-ventricular opening. Relief of pulmonary congestion is the most constant indication for treatment. This has been met by venesection, by cups, by rest, by digitalis; but since digitalis is more of a tonic to the cardiac muscle than a stimulant to the vagi, we often find its use unsatisfactory. The indication is to slow the rhythm of the heart, and thus permit the right heart and left auricle to empty themselves into the left ventricle; *afterwards* it becomes needful to administer cardiac stimulants. In the out-patient department of the Children's Hospital of Philadelphia, the treatment of cases of mitral obstruction with convallaria has been most encouraging, using ten drops of the fld. ext. three or four times per diem, with or without the associated use of digitalis.

(3) Irregular heart as a symptom of mitral regurgitation has been less positively benefited, since in these cases cardiac irregularity is a symptom of cardiac fatty degeneration. In mitral obstruction irregularity is an initial symptom.

(4) Convallaria loses its effectiveness in valvular heart-disease in proportion to the amount of fatty degeneration of the heart. Assuming as proven that the vagi are stimulated by digitalis, and that the reduction in number of the cardiac pulsations when digitalis is exhibited, is due to this stimulation, it has been commonly found that when there is advanced fatty change in the heart the inhibitory effects of digitalis are less perfect, since there is less muscle through which the vagi could assert their influence. Moreover, in fatty heart a more powerful cardiac stimulant, such as digitalis, is required and not a regulator. In advanced valvular heart-disease or cardiac failure in the catarrhal nephritic forms of Bright's disease, convallaria has not proven as useful as digitalis.

(5) The drug is of great service in cases where palpitation and dyspnoea, rather than deficient cardiac systole are the prominent features. Broadly speaking, cases of phthisis or asthma in which

palpitation and dyspnoea are prominent symptoms, before cardiac failure from advanced fatty change ensues, are much benefited by this drug.

(6) Its effect is often brilliant in purely functional heart disorder, especially palpitation with irregular cardiac action dependent on general debility, and in cases of anæmia or hysteria. It is sometimes an efficient remedy in the irregular action of the heart caused by tobacco.

In conclusion, it is proper to state that the preparation employed has been the fld. extract. (Parke, Davis & Co.) The doses 15-20 drops given every three hours in adults, until the desired effects have been produced. Smaller doses have proven entirely negative. The drug is by no means a substitute for digitalis, which combines the properties of a cardiac tonic and regulator to a greater degree than any other one drug in our pharmacopoeia. Convallaria has two great advantages over digitalis, which have been brought out by Beverly Robinson, M. D., in the *Medical Record*, for April 14, 1883.

(1) Convallaria is well borne by the stomach of most patients suffering with chronic cardiac disorders. The uræmic condition in advanced cardiac and renal cases will often account for its rejection.

(2) Cumulative effects are not to be apprehended. Nevertheless, the action is usually prompt and therefore a week or ten days' use will, I believe, decide positively the value in any special case. It would appear that the clinical action of Convallaria is not in direct harmony with the results of laboratory investigation and experiment. One must be cautious in closely pushing the deductions from experiments in the laboratory, until they are abundantly confirmed. Moreover, cardiac disorders present more cases of idiosyncrasy than other forms of disease, and we must expect to find some cases in which Convallaria is inoperative, although it is apparently indicated. Convallaria is far inferior to Digitalis as a diuretic; indeed, I have had such negative results that it is difficult to assign to it a distinct value in this connection. This presentation of a personal experience with Convallaria has seemed to me permissible only because the investigation of the drug is in such an incipient stage. May I hope that in another year additional results of experience in its use may be contributed, and the common good of the greatest number be advanced?

At eleven o'clock a special train conveyed the members of the Society, their wives, daughters and friends to the State Hospital for the Insane, in the southeastern district of Pennsylvania, or, as it is generally known, the Norristown Asylum, which is beautifully situated on the hills just outside of that city. Arriving a little before twelve, an hour was spent in a tour of some of the male and female wards, there being some 300 in the visiting party. The resident physicians showed the visitors through the peaceable wards, with results entirely satisfactory as far as the inspection went. No one could fail to be impressed above all things with the great cleanliness of the floors, walls, wood-work and furniture, and, indeed, of everything and everybody about the institution.

The most striking feature for a stranger, however, was unquestionably the vast area covered

by the hospital buildings. There are 960 inmates, male and female, black and white, yet there is no indication of crowding, and other buildings have just been completed, and are yet unoccupied.

After a substantial and well-arranged cold collation, in a long hall of one of the new buildings, the Medical Society reconvened in the Asylum Chapel, close at hand.

Dr. Benjamin Lee then read the report of committee appointed at the last meeting of the Society to memorialize the Legislature on the subject of the codification of the insanity laws, in which the committee stated that they found their action anticipated by Governor Hoyt, in his excellent creation of the Lunacy Commission. The report was received and the committee discharged.

Dr. William S. Little, of Philadelphia, read a paper on

"THE POSSIBILITY OF ABNORMAL OCULAR CONDITION THROUGH THE SYMPATHETIC SYSTEM IMPAIRING THE FUNCTIONS OF THE UTERUS."

After reviewing the influence diseases of the uterus and its appendages have upon the eye, beginning at puberty and continuing to the menopause, both in the non-pregnant and pregnant condition, as has been described by Prof. Förster, of Breslau, under the head of *Hysterica Kopia* and been fully corroborated by many observers, and more recently maintained in the Bradshaw Lecture before the Royal College of Physicians, England, delivered the past year by E. Long Fox, M. D., F. R. C. P., on the influence of the sympathetic on disease, in which he relates the influence of irritation from the hypo-gastric plexus affords the most striking illustration producing wide-spread and distant effects. Next, on the other hand, is taken up the influence the eye has when it is the seat of irritation from unnecessary effort in seeing, upon the nervous system and some organs of the body, as has some years since been promulgated by Dr. S. Weir Mitchell, and first tested by Prof. Wm. Thomson, M. D., and is now a very interesting field in ophthalmic medicine.

Dr. J. M. Duncan, of St. Bartholomew, while lecturing on the remote and indirect symptoms of the uterus and its appendages, asks the following: "Are there no uterine symptoms, or disorders, or diseases which are secondary to other diseases, indicative of them or caused by them? Should the uterus and its appendages be looked on as always governing and disturbing, and not itself occasionally governed or disturbed?"

The purpose of the paper is to trace in one case at least, the possibility of reflex irritation as produced from a marked optical defect, differing in each eye; extending as far as the uterus and impairing the function; regions more approximate and other organs nearer the eye being markedly affected as well. In the case in question a married lady, 34 years of age, was seen in Feb., '81, suffering from severe headache, pain in eyes, pain down region of neck, gastric symptoms and marked hysteria. Examination of her eyes revealed a difference of refraction in each, one being hypermetropic with hypermetropic astigmatism, and the other having hypermetropic astigmatism.

Relief from nearly all the symptoms rapidly followed the correction of the optical defect. At the time of treatment no recognition was made of uterine trouble or impaired function.

It was not till some one year and a half afterwards, she being in the meantime perfectly well, that I learned she had given birth to a female child, the same not having occurred for twelve years, and the present being the second pregnancy; there had been no miscarriages.

The fact of this pregnancy having occurred so soon after the relief of her other troubles which had persisted so long, and been relieved by correction of her optical defect, has drawn my attention to the influence that had existed and re-acted as far as the uterus and impaired its function.

A paper entitled

"HYGIENIC MANAGEMENT OF CONSUMPTION; OR, HOUSE-PLANTS AND LUNG DISEASE,"

Was read by Dr. J. M. Anders, of Philadelphia.

As science develops, popular traditions often become disintegrated or vanish away. In the light of present knowledge there remains little room for doubt of the beneficial influence which house-plants are capable of exerting in the sick chamber.

In the first place, it seems incumbent to present a brief summary of the facts pertaining to the effects of plants in the air of houses, which have been established by my own researches.

First, that plants transpire (exhale) aqueous vapor with great rapidity, the rate having been carefully estimated at one-fourth ounce by weight per square foot of leaf surface for twelve diurnal hours.

Secondly, through this process of transpiration they have the power to increase the humidity of the atmosphere of an apartment to any degree that may be desired, by simply regulating the amount of leaf surface.

Thirdly, that the vapor emitted from plants is most probably changed and medicated to some extent by passing through the plant, and is presumed to possess greater sanitary value than ordinary humidity.

Fourthly, recent experiments by the writer, the results of which have not yet been published, render it highly probable that flowering plants have the power of generating and emitting ozone.

In a paper published by me in the *Philadelphia Medical Times* of May 8, 1880, the theory of their utility in lung affections was further supported by proof of a practical character. I propose to collect here all the histories thus far reported as bearing out this idea from a practical standpoint, in order that the profession may be able to judge more intelligibly as to the value of house-plants as hygienic or therapeutic measures in consumption. Whether or not we consider the theory of Koch as having been carried to a demonstration, the words of John Locke uttered long ago still hold with reference to phthisis, viz., that "prevention is better than cure," and far cheaper. Indeed, it is a question whether in this disease the only cure is not in most cases, I will not say all, prevention.

And should the careful observations of Koch be fully confirmed by future investigations, it is much to be feared that all efforts at finding a specific to destroy the parasite within the human body would be wasted on a forlorn hope. How to prevent the development of consumption should be a subject of vital interest to every practitioner of medicine, in view of the great prevalence and incurable nature of the disease, and also on account of the acknowledged fact that half, at least, of all cases are preventible. The family doctor very generally has an opportunity of knowing the inherited tendencies of his patrons, and should he be aware of the presence of predisposition to tubercular disease in a family, it becomes his duty to point out the danger and how to avoid it.

With no intention of underrating the importance of other measures usually recommended by writers for guarding against this dread disease, I wish to present here the evidence obtainable in favor of house-plants as preventive agents. In the article before referred to, are given the results of some practical observations bearing upon the same point, from which I shall have to borrow a brief summary. A visit was made to thirty florists and gardeners of Philadelphia, of whom twenty, with ages ranging from twenty-five to eighty years, are strong and vigorous, and have always enjoyed good health. They all work from ten to sixteen hours daily, and have followed this pursuit for from six to sixty years.

Two of this number, however, a father and a son, gave a marked family history of the disease in question, and have died of the disease after quitting their occupation. The father, although strongly predisposed to phthisis, followed the occupation of florist from early life up to the age of sixty, and during all those years was in good health. When sixty years of age, while he was assisting at the erection of a church, he met with an accident which injured his ribs and disabled him for work. But a few months later he went into consumption, which quickly proved fatal. Now, may not the fact that he was unable to be among his plants have had something to do with his last illness?

The son died at the age of thirty-six years. He was engaged in gardening from boyhood up to within a year of his death, continually at work among his plants. During all the time he followed this vocation, he enjoyed fair health. A short time prior to his death he forsook his calling and took a store in the same city, and almost simultaneously he became a victim to consumption, which caused his death in a short time.

During the spring of 1882 there came under my care a brother of the last patient, whose case has not been reported, giving the following history: He was thirty-six years of age; had lost his brother and father from consumption. He stated that he followed the occupation of florist and gardener from the age of fifteen years up to about one year previous to my having seen him; that he worked almost continually among his plants from eight to twelve hours daily, and during this whole period he enjoyed good health. He now abandoned his former calling; took a small store, and dealt only in cut flowers. After pursuing this business for a few months, his gen-

eral health gradually failed, and cough set in, which gradually increased. Being of very careless habits, the patient neglected this cough for a long time, and when he first applied to me, the physical signs showed there was extensive softening of the upper lobe of the left lung and slight crepitation at the apex of the right one. The future course of the case was typical of phthisis, and terminated fatally about a year later.

The fact that these two brothers had followed floriculture for so many years in good health, and so soon after making a change in their occupation they both fell into consumption is, to say the least, very suggestive. The father, who continued his calling as a florist until late in life, escaped the disease until, as a result of an accident, he was incapacitated for work, when he shared the sad fate of his unfortunate sons. Is it not reasonable to believe that had not these young men deserted their plants they would likewise have escaped the disease, at least at so early a period?

A striking example of the value of plants in preventing the development of the disease in question is recorded by Dr. Ely McClellan, U. S. A., in the *Philadelphia Med. Times*, Feb. 26, 1881. He says: "For the past three years there has been almost constantly under my observation a case which seems to corroborate the views expressed by Dr. J. M. Anders in his paper on the Hygienic and Therapeutic Relations of House-plants—E. M., a gentleman thirty years of age, who belongs to a family in which there is a marked history of phthisis pulmonalis. His physique would indicate that he might be subject to the disease, but he has as yet escaped its development. The history of the case involves the families of both father and mother. The father, although born of tubercular parents, escaped the disease, but the mother died at comparatively an early age, leaving a family of five children, four of whom have died of consumption. Of these children three died between the ages of twenty and twenty-five years, one died in his thirty-ninth year after a long illness, the last two years of which were under my observation.

"E. M. is the youngest of the family. His life with the exception of the last eighteen months has been devoted exclusively to sedentary pursuits. At twenty-three he married, and as he was then engaged in an occupation which required his residence in an isolated locality, both for amusement and occupation, his wife began the cultivation of house-plants. She soon became an enthusiast, and a profusion of plants, especially the foliage varieties, accumulated in her house. As they resided in an extremely changeable climate, when during the cold months constant watchfulness was necessary for the preservation of plants, her bed-room and the adjoining sitting-room were arranged for that purpose.

"Before his marriage E. M. complained of, as he expressed it, a weakness of the chest and a constant liability to take cold. Since his marriage, with the exception of an occasional ailment, he has seemed a healthy man and it is but reasonable to attribute his escape from the disease which had destroyed so many of his family, to the fact that he lives and has lived for the past seven years in apartments well stocked with thrifty plants."

Four cases illustrating the value of plants as remedial agents in confirmed phthisis were next given, two of which have been under the writer's own observation; the history of one of these cases was received from my friend, Dr. Hiram Corson, of Conshohocken. The remaining one appeared in the *Christian Advocate* for July 29, 1880.

I have here given a number of cases tending to show the value of plants as preventive and remedial agents in phthisis, too few perhaps to furnish a basis for definite conclusions, still they seem to me of sufficient importance to call for more extended observation in this direction.

Whether we convert the sick room into a floral chamber, or resort to a neighboring greenhouse, such a refuge may be looked upon as a miniature health resort, and possesses important advantages over ordinary health stations. They are within reach of all, and every practicing physician is familiar with the fact that a change of climate is out of the question in many instances, for financial or other reasons. Again as it is well established that a change of climate is of no avail unless the new residence is more or less permanent, it is well to note that this inexpensive substitute does not entail prolonged separation from home comforts and social ties. It is recommended that the patient should assume a care of the plants which to most persons becomes a pleasing occupation, besides their cultivation and study are well adapted to relieve mental tension or depressing ennui.

During the warm season the patient can obtain the beneficial influence of the plants by the culture of flowers and plants and spending as much time as possible among them in the open air. It is not claimed for plants that they can rise to the position of a specific in this dread disease, but it would seem that they are capable of bringing about an arrest of the disease, or even cure in some instances with the aid of remedies and other sanitary precautions employed in such cases.

In order to obtain good results from this method, particularly when the living and sleeping rooms are taken as a refuge for the invalid, the cultivation of the plants, the extent of leaf surface, the size and exposure of the room, ought to be well understood and receive due attention.

As to the amount of plant life. And first in the selection of plants the following rules should be observed: "First, that they have soft thin leaves; secondly, foliage plants, or those having extensive leaf surface are to be preferred; thirdly, those which are highly scented (as the tuberose, etc.), should be avoided, because they often give rise to headache and other unpleasant symptoms."

As a broad rule it may be stated that a greater proportion of plants is essential in advanced stages, when cavities exist in the lungs, marked hectic fever or a highly sensitive nervous system, such a ratio as employed in Miss S.'s case, viz.: three dozen thrifty plants having a leaf surface of four square feet each, in a room twelve by twenty feet would produce an effect suitable in such cases. On the other hand in the earlier stages of chronic phthisis, as well as when cultivated as preventive measures, a somewhat less ratio might suffice.

It is important to maintain an equitable temperature (68° to 74° Fahr.) so that the air of the room may not have a chilling effect.

Growing plants doubtless have other spheres of applicability of almost equal importance to their value in lung disease but these cannot be discussed at present writing.

Dr. Benjamin Lee, of Philadelphia, submitted the following, which was directed to be published in connection with the report of the proceedings of the session:

Resolved, That this society, after listening to the numerous able papers upon the proper care of the insane, which have been offered during the present session, in which this important question has been discussed from every possible standpoint with the utmost freedom of expression and in a truly scientific spirit, consider the following conclusions justifiable:

First. That the problems connected with this subject are of so intricate and delicate a nature, interesting in themselves on the one side with the most sacred social and domestic interests of life, and on the other calling the highest order and scientific attainments of no mean value, that only those who have made them the subject of careful and conscientious study are competent to attempt their solution or to criticise those who are endeavoring practically to work them out.

Second. That the attempt to create the imputation that the incarceration of sane persons in institutions for the insane from improper motives, is one of the dangers of the day, is an unworthy aspersion upon our profession and should be frowned down by all reasonable persons, whether lay or professional, as utterly unsupported by evidences.

Third. That in the Medical Superintendents of our Insane Hospitals and their assistant physician of both sexes, we recognize a body of workers second to none in our profession, in unselfish devotion to the interests of humanity, in elevation of motive and high standard of personal character and general attainment.

Fourth. That it is evident that, in order to place such institutions throughout our country in a position to properly fulfill their functions as hospitals for the treatment and cure of diseases of the brain, our State Legislatures must be made to feel the necessity for making such appropriations as shall greatly increase their medical staffs, and furnish them with all the necessary appliances for the investigation of disease. These resolutions were unanimously adopted.

Dr. Curwen offered by way of a resolution, that the president of the Society be requested to appoint a committee of three members on each of the following subjects: Medicine, surgery, diseases of women and children, ophthalmology, nervous diseases, insanity, and idiocy. The duty of the committees shall be to prepare a series of questions calculated to obtain the history and treatment of the different forms of disease.

The following standing committees for 1884 were announced:

On Insanity and Idiocy—John Curwen, J. N. Kerlin and S. Schultz.

On Medicine—James Tyson, C. K. Mills and R. H. Chase.

On Surgery—R. J. Levis, S. M. Ross and James McCann.

On Diseases of Women and Children—A. H. Smith, William Goodell and C. A. Rahter.

On Ophthalmology, etc.—C. S. Turnbull, P. D. Keyser and J. A. Lippincott.

Nervous Diseases—S. Weir Mitchell, J. L. Stewart and J. Z. Ziegler.

To deliver addresses for next year the following were appointed:

Medicine—M. H. Daly, of Pittsburgh.

Surgery—John B. Roberts, of Philadelphia.

Obstetrics—Jacob Price, of West Chester.

Hygienic and State Medicine—J. G. Lee, of Philadelphia.

Mental Disorders—Dr. Alice Bennett, of Norristown.

Ophthalmology in its Relation to Medicine—Dr. W. S. Little, of Philadelphia.

On motion of Edward J. Jackson, of West Chester, a vote of thanks was extended to the Montgomery County Society; to Drs. J. K. Weaver and Mary Stinson; to George W. Rogers, Esq.; to the Faculty of the Polyclinic College, and to the Hospital for Skin Diseases of Philadelphia, for their liberality and hospitality during the session of the State Medical Society.

A vote of thanks was subsequently tendered the Board of Trustees of the Hospital for the Insane for their kindness to the profession.

Dr. H. H. Smith, President-elect, was conducted to the chair, the retiring President, Dr. Varian, vacating a short time prior to adjournment.

At four o'clock, the session of 1883 was adjourned.

American Medical Association.

The next annual meeting of the American Medical Association will be held in Cleveland, June 5th to 8th, inclusive. All railroads west of Pittsburgh, Salamanca, and Buffalo, east of Chicago and south of Cleveland will carry delegates and members of their families to Cleveland at one full fare, and return them on certificate signed by X. C. Scott, M. D., Cleveland, as chairman of the Committee of Arrangements (certifying that they have been in attendance at the meeting of the Association) at one cent per mile. The trunk lines east of Buffalo, Salamanca and Pittsburgh, and lines west of Chicago, have refused to make any reduction. The rates per diem at the hotels will be: Kennard House, \$3.00; Weddell House, \$3.00; Forest City House, \$2.50 to \$3.00; American House, \$2.50; Hawley House, \$2.00; Striebinger House, \$2.00; Clarendon House, \$2.00, and Prospect House, \$2.00.

Unhealthy Dwellings in Rome.

From an article by Dr. E. Sernicoli in a medical journal published in Rome, we learn some startling facts concerning the way in which the poor live. He visited one room, forty feet long, fourteen wide, and ten high, which was inhabited by twenty persons; and sometimes he would find as many as ten, fifteen, and even twenty persons living in two rooms, each of which was less than ten feet square. Many of them border upon close courtyards, to which the rays of the sun never penetrate, and in them the *cicorari* or costermongers keep the fruit and vegetables they hawk

about the streets for sale. If Dr. S. will honor us with a visit, we can show him equally unsanitary conditions in both New York and Philadelphia.

Greek Wines.

The *Am. Jour. Pharm.* says that Greek wines are now extensively exported to all parts of Europe, in consequence of the devastation of numerous vineyards by the phylloxera, which thus far has not made its appearance in Greece. It is more particularly the volcanic island of Santorin where many wines are produced, closely resembling those of Spain, Sicily, Southern France and the Cape wines; these wines are called vino santo. The concentrated, unfermented grape juice, known in Turkey as *betmes* (see *Amer. Jour. Pharm.*, 1875, p. 534) is now largely exported to Central Europe, where it is fermented with juice of the native grapes, and thus employed for improving the more acidulous wines of more northern latitudes.

Who Discovered the Anæsthetic Properties of Ether.

Gaillard's Medical Journal says that Governor Stephens, of Georgia, made the proposition to place in the National Statuary Gallery at Washington the statue of Dr. Long, of Athens, Georgia, who was, said Governor Stephens, "two years ahead of Wells and Morton in his application of sulphuric ether for the relief of pain in surgical operations, and to whom, therefore, belongs the honor and glory of this greatest discovery of modern times." Dr. Long's claims as a discoverer were strongly advocated by Dr. J. Marion Sims some years since.

Medical Society of New Jersey.

The next annual meeting of the above Society will be held in Congress Hall, Atlantic City, on Tuesday and Wednesday, June 12 and 13, commencing on Tuesday, at 4 o'clock p. m.

A complimentary train over the West Jersey and Atlantic Railroad will be at Camden on Tuesday, at 12:15 o'clock p. m., in readiness to convey all to Atlantic City who may wish to attend the meeting.

WM. PIERSON, Secretary,
Orange, N. J.

Lectures on Orthopædic Surgery.

The Hospital Committee announce that Dr. A. Sydney Roberts will give a special course of lectures on "Orthopædic Surgery and Joint Diseases" at the Philadelphia Hospital. The lectures will be illustrated by numerous cases, specimens, and diagrams, and will be delivered in the clinical amphitheatre on Mondays and Fridays, May 4, 7, 11, 14, 18 and 21, at 4 p. m.

American Laryngological Association.

The Fifth Annual Congress of this Association will be held in the Hall of the Academy of Medicine, New York city, May 21, 22, 23. Dr. D. Bryson Delavan, of New York, is the Secretary.

Prizes.

The Spanish Medico-Chirurgical Society offers two prizes for the best treatises respectively on the Contagiousness of Lung Disease and the Formation and General Treatment of Hernia. The former prize will consist of 250 pesetas (about \$45) and fellowship of the Academy; the latter of 750 pesetas (\$135) and the fellowship. The essays must be written either in Spanish, Portuguese, French, or Latin.

Items.

—The American Medical Association meets June 5, 1883, at Cleveland, Ohio.

—An even temperature is necessary for the staining of the tubercle bacilli, say about 100° F., which can be obtained by means of a water bath.

—Dr. B. W. Richards, in a recent address, went so far as to declare that he had never seen a healthy child, nor one that had not in it either some ancestral or latent constitutional disease.

—In fifty severe cases of acute tonsillitis, due to exposure to cold, Mr. R. N. Hermazdi effected a rapid cure by the administration of twenty-grain doses of salicylate of soda every four hours. In no case did suppuration ensue.

—According to the *Louisville Medical News* the best application for ear-ache in children is a few drops of a warm solution of atropia, one to four, and allowed to remain ten or fifteen minutes, and then allowed to run out by turning the head over. Usually a few applications will suffice.

—The National Health Society, London, has introduced a form of garment, made of mackintosh, to be worn by those people who are compelled to enter the apartments of persons suffering from contagious diseases. Used in conjunction with a medicated cotton respirator, it is said to be a protection against contagion.

—At a recent meeting of the sanitary authorities of Darlington, England, it was reported that a gentleman from London had entered a house in the town, in which two persons had lately died of small-pox, and sold the furniture, although he was cautioned not to do so until it had been disinfected. Thirty cases of small-pox had since broken out.

—A hardware merchant of Liberty street, Pittsburgh, has become insane, and possessed of a most peculiar mania. He imagines that he is dead, and he will not take any food. He declares that as he is a corpse it would not be proper to eat anything, and his physicians have been compelled to pour soup and beef tea between his clenched teeth to prevent him from starving.

—The *Ceylon Observer* reports that the practice—now pursued for some years—of “shaving” bark off living cinchona trees has not been productive of any ill effects. On the contrary, the bark “renews,” with even a larger percentage of alkaloid. Some trees have been thus treated on five successive occasions without their vitality having, to all appearance, been in the least impaired.

—Some statistics, just published, show that in 1870, the quantity of malt liquors, chiefly lager beer, produced in the United States, was valued at \$55,000,000, while in 1880 the value reached the sum of \$101,000,000. During the same period the increase in the production of distilled liquors was comparatively small, the value of the product being \$36,000,000 in 1870, and \$41,000,000 in 1880. The figures quoted show that whisky-drinking is giving way to the drinking of light beer—a fact which should be welcomed by the friends of temperance.

OBITUARY NOTICES.

JOHN CARY WHITING

Was born in Hampton, Va., July 3, 1834, and was educated at the Hampton Military Academy, under his uncle, Col. John B. Cary. He went South to Mobile, Ala., January, 1854, and studied medicine under the tutorage of Drs. J. C. Nott and H. F. Hustis. He entered the Marine Hospital at Mobile, 1855, as an interne; attended a course of lectures at the University of Louisiana, New Orleans, during the winter of 1857–58, and attended his second course of lectures at the University of Pennsylvania 1858–59, when he received the degree of Doctor of Medicine. He returned to Alabama in October, 1859, and began the practice of medicine in Baldwin county, continuing there until May, 1860. He then moved to Pensacola and married Miss Clara R. Hyer, June 21, 1860. In the fall of 1860 he located in Pensacola, conducted a drug business and practiced medicine. He entered the service of the Confederate States as assistant surgeon early in 1862, and continued in the service until the close of the war.

During his service he was promoted to the rank of surgeon and assigned to various stations—was at Montgomery, at Mobile in the Medical Director's Department, and at a camp of instruction in North Carolina, where he was taken prisoner, was exchanged, and afterward assigned to the hospital at Greenville, Ala., where he remained until the close of the war.

In September, 1865, he returned to Pensacola, where he resumed the practice of his profession.

Dr. Whiting was one of the founders of the institution known as the Pensacola Infirmary, which had its advent in 1868. In this he manifested a profound interest, and was diligent in the discharge of every duty connected with it, until a short time after the termination of the epidemic of yellow fever in the fall of 1882, feeble health compelled him to entrust it to the charge of one of his professional confreres, while he sought the beneficial influences of travel and a change of climate; in this he was unhappily disappointed. Returning to his home, he lingered, with occasional flattering hopes of recovery, until on the 16th of April he met his fate. He bore his sickness with patience and fortitude, and departed this life calmly and peacefully—without a struggle.

Dr. Whiting was devoted to his family, kind and attentive to his patients, and his many virtues won the love and esteem of all who knew him.

DIAGNOSIS, PROGNOSIS AND TREATMENT OF MITRAL STENOSIS.*

BY J. T. ESKRIDGE, M. D.,

Physician to the St. Mary's and Jefferson Medical College
Hospitals.

The mitral presystolic murmur, although standing about fourth in point of frequency of endocardial murmurs, is, nevertheless, of sufficiently frequent occurrence to be recognized by everyone at all familiar with cardiac auscultation. The mitral presystolic murmur and its diagnostic characters were first clearly pointed out by Fauvel, in 1842, (vide article by Flint, the *American Journal of the Medical Sciences*, April, 1882).

Two varieties of this murmur have been described. One variety, by far the more frequent, characterized by Flint as vibratory or blubbery, is rough; the other is soft or "bellows-like." Fauvel described the former, and Walshe and Markham the latter variety of the murmur. Flint says: "A soft mitral presystolic murmur is a very rare physical sign. A rough mitral presystolic murmur, on the other hand, is by no means rare." To support his view of the frequency of the latter murmur, he observes: "From 1858 up to the present time (1882) it is not an exaggeration to say that many hundreds of examples have come under my observation during this period, in hospital and private practice. Prior to my publications just referred to," (vide Flint's work on "Diseases of the Heart," 1852, and the *American Journal of the Medical*

Sciences for 1862) "so far as I know, no writer in this country had described this murmur. I believe that I may add that for many years after those publications it was not recognized as a distinct murmur but by very few of those who gave more or less attention to auscultation, and, indeed, at the present time (1882) it is not so recognized by many."

Contrary to the views expressed by Hope, Walshe, Markham, Flint, and others, Hayden, in his exhaustive treatise on "Diseases of the Heart and Aorta," says: "I have already stated that the murmur of mitral obstruction is harsh and unpleasant to the ear; I have never met with an example which constituted an exception to this statement, notwithstanding that Markham maintains that softness is a quality essentially characteristic of presystolic murmur." My own experience is nearly in accord with the statement found on page 216, vol. I. of Hayden's work just referred to. It reads: "The quality of the presystolic murmur is always more or less harsh, and usually decidedly so." In the numerous examples of mitral presystolic murmurs which have come under my observation, the accuracy of the diagnosis in many of these cases having been verified by *post mortem* examination, I have not met with a single instance of a soft mitral presystolic murmur. The quality of the mitral presystolic murmur, in my experience, has varied much, all so far having been more or less harsh, while the larger portion have been decidedly so. In every case that has come under my care, presenting mitral direct and regurgitant murmurs, the presystolic has been harsher than the systolic murmur. I do not wish to be understood as say-

* Read before the Medical Society of the State of Pennsylvania at Norristown.

ing that a soft mitral presystolic murmur never occurs, but only, that I have never met one.

Speaking from personal experience, I have found mitral stenosis complicated with mitral insufficiency in about two-thirds of the cases; others state that the association of both mitral lesions occurs in a still greater proportion in mitral obstruction. Hayden thinks that about one-half the mitral obstructive lesions are unattended by mitral regurgitation.

In the diagnosis of mitral stenosis a presystolic murmur and purring thrill are the physical signs of most importance. The quality of the murmur, as I have heard it, and as most authors have described it, is more or less rough, and in the majority of cases very decidedly so. Possibly, in a few instances the murmur is soft, but it must be exceedingly rare, as I have never met with a single example of it, although about forty of the harsh variety have come under my observation during the last eight years. The mitral presystolic murmur, whatever be its quality, begins before the first sound of the heart, and ends when the latter begins. It never occurs with the first sound, whereas a mitral regurgitant murmur is never heard before the first, but always synchronously with it. The mitral presystolic murmur is harsh, begins rather abruptly, increases in loudness, and ends suddenly while the ear is intent on listening for its continuation. The carotid pulse, and apex beat of the heart can be felt to follow the presystolic murmur. If attention is paid to this, when both mitral presystolic and systolic murmurs are present, these may be observed to be separated by an appreciable interval of time. Under such circumstances the harsh, abrupt ending of the presystolic will be in marked contrast to the gradual lessening of the loudness of the systolic murmur. Moreover, in the majority of cases, the former murmur will be found to be harsher and more unpleasant to the ear than the latter.

If now the stethoscope be placed in the left axillary region, the systolic murmur, if not louder in this position, will be frequently more clearly defined, while the presystolic murmur will have disappeared or become very faint. In some cases in which both mitral murmurs have been present, I have been assisted in differentiating the murmurs by comparing the stethoscopic observations made over the præcordial region with those observed at the lower angle of the left scapula. In the former situation, the systolic murmur is preceded by an abrupt, harsh murmur, which ends abruptly; in the latter position, with infrequent

exceptions, is heard only the systolic murmur, which neither begins nor ends so abruptly, nor except in probably rare instances, is as harsh as the first part of the murmur heard anteriorly.

The abruptness of the ending of the mitral pre-systolic murmur is easily understood when we remember that the current of blood which gives rise to it, passing through a narrowed auriculo-ventricular orifice, is suddenly reversed during the ventricular systole.

The mitral presystolic murmur is most intense about the left fourth costal cartilage, or just above, and a little to the right of the apex beat. It is absent or faint at the base of the heart, especially at the right base, is rather infrequently heard in the left axillary region, and some writers on physical diagnosis say it is never heard posteriorly at the lower angle of the left scapula, although Hayden states that in one instance he heard the presystolic murmur in the last position.

When a presystolic murmur exists, is it easy to diagnose it? Dr. James Andrew states that "it must be confessed that the diagnosis of a presystolic from a systolic ventricular murmur is one of the most difficult tasks in the physical examination of the heart, and is often all but impossible." (Hayden on Diseases of the heart and Aorta, p. 202). Flint observes: "It may be said of a truth that when its distinctive points have been fully understood and verified by examples, no one of the cardiac murmurs is more readily recognized than the mitral presystolic murmur." (*The American Journal of the Medical Sciences*, April, 1882.) On this point Flint is in accord with most observers who have given special attention for a length of time to the diagnosis of mitral stenosis. Of late my experience has been, when the heart is not acting very rapidly or tumultuously, that I have not encountered much difficulty in satisfying myself of the presence or absence of the mitral presystolic murmur. This murmur, more than all others, requires for its appreciation, clear recognition of the cardiac sounds; if the heart, therefore, be acting so rapidly or tumultuously that its systole and diastole cannot be defined, it is impossible to diagnose this or any other heart murmur, although a loud one may be present. To be able to readily distinguish the presystolic from the systolic murmur requires very careful training of the ear to appreciate the rhythm of endo-cardial murmurs.

Hayden calls attention to five conditions which may give rise to murmurs simulating the mitral presystolic murmur. With proper care, all these

sources of error, as he clearly points out, may be avoided.

Is mitral stenosis always accompanied by a presystolic murmur? Walshe says, "the murmur is frequently absent."

"Dr. Waters believes that presystolic murmur is far more frequently absent than present, even when there is great obstruction at the mitral orifice." (*Diseases of the Chest*, second edition, 1873, *vide* Hayden on Diseases of the Heart and Aorta, 1875).

DaCosta says: "Undoubtedly there are instances in which no murmur reaches the ear to show that the valves are damaged. All the instances I have met with of valvular disease, unaccompanied by blowing sounds, have been instances of diseases at the mitral orifice, and of extreme narrowing of that orifice. They were all attended with excessive irregularity of the action of the heart, and with hypertrophy. They all produced difficulty of breathing. They all presented this peculiar clacking sound most marked near the apex." (*Medical Diagnosis*, DaCosta, 3d edition.)

Flint states that "It is by no means true that a rough mitral presystolic murmur is present whenever an obstructive mitral lesion exists. A mitral obstructive lesion may be found after death, when a mitral presystolic murmur had not been produced." Flint thinks when the mitral murmur is absent, a mitral stenosis existing, that the obstruction is due to "contracted, thickened, or calcified valves," incapable of being set in vibration by the current of blood from the auricle into the ventricle. In reference to the presence of a mitral presystolic murmur in mitral stenosis, Hayden's propositions (c), (d) and (e) read as follows:

"(c) That it is never permanently absent in cases of this lesion;

"(d) That it is very seldom temporarily absent in such cases;

"(e) That in these exceptional instances, the explanation of its absence is almost invariably to be found in debility of the heart." (*Diseases of the Heart and Aorta*, p. 904.)

Dr. Balthazer Foster observes: "A special peculiarity of the presystolic murmur is its variability: it is the only organic murmur which disappears and reappears as the heart conditions change. For instance, a murmur, inaudible while the patient is at rest, is developed by a little exercise; or again, an irregular tumultuous action of the heart masks all murmur, which becomes distinct as the heart

steadies down under digitalis." (*Dictionary of Medicine*, Quain, 1883.)

It will be observed that Hayden lays great stress on the presence of a mitral presystolic murmur, and believes that it is never absent except in cases with extreme feebleness of the heart. Flint, while admitting its absence from the feeble condition of the heart late in the disease, thinks the character of the valve lesion accounts for its absence in some cases, the valve being in the cases in which no murmur is present at any time, incapable of vibrating on account of the extreme rigidity of the leaflets from calcification, etc. Of the six cases coming under my observation, in which the post-mortem examination showed mitral stenosis, the murmur was absent in only one individual. In this patient, during my attendance on her, general dropsy and great pleural and pericardial effusion existed, with a feebly acting heart. Hayden says, "in two cases only out of a total of eighty-one, or in the proportion of 2.4 per cent. was the murmur actually suspended, under any personal observation, yet in both of these it was resumed after a brief interval." Of his fatal cases (fifteen) the murmur was not heard by him in three; these, for the most part, presented themselves to him after the circulation had become very weak. In three cases in which no mitral presystolic murmur was heard, I diagnosed mitral stenosis from the presence of thrill and associate symptoms. The correctness of the diagnosis in these cases has not been verified to my knowledge by post-mortem examination, or even the development of a murmur.

Is a mitral presystolic murmur present only when mitral stenosis exists, or, in other words, is the murmur pathognomonic of mitral obstruction? Here, again, authors differ. Flint says, "A well-marked, rough mitral presystolic murmur may be present, and not be due to any mitral lesion." I am not aware of this clinical fact having been stated by any other medical writer. It was stated in my article on the Cardiac Murmur, in 1862, and I have reiterated it in subsequent writings. In the article just referred to, I gave the synopsis of the history of two cases in which the presystolic murmur was noted during life, and no lesion at the mitral orifice sufficient to account for the murmur found after death. I have met with several instances since that time. In all, there existed aortic lesions which occasioned free regurgitation." (*The American Journal of the Medical Sciences*, April, 1882). Flint's observa-

tions, although first published about twenty years ago, so far as I am aware, have not yet been verified. I have met with only one case in which an aortic regurgitant murmur was associated with the mitral presystolic murmur. In that instance, the aortic valve was incompetent, and the mitral orifice was very much contracted. Flint's explanation of the occurrence of a mitral presystolic murmur without mitral stenosis is, to say the least, ingenious, although it has not escaped criticism by Hayden. Dr. Hilton Fagge, whose memoir was published in 1871 (Hayden on Diseases of the Heart and the Aorta), seems to have entirely overlooked or disregarded the observations of Flint. Fagge states: "Hitherto, I believe, no single instance has been recorded in which a presystolic murmur has existed during life, and in which the mitral orifice has not been found after death to be very decidedly narrower than usual." "Dr. Balfour declared his opinion in 1871 that presystolic murmur 'may be conclusively accepted as distinct proof of the existence of a permanent deformity, even though the murmur itself should subsequently disappear, as it frequently does.'" Hayden remarks: "Judging strictly within the limits of my own experience, and drawing my conclusions from statistics given, I feel justified, therefore, in holding,

"(a) That presystolic murmur is pathognomonic of auriculo-ventricular narrowing;

"(b) That it is never present where auriculo-ventricular narrowing does not exist;

"(c) That it is never permanently absent in cases of this lesion."

Foster says, the pathognomonic sign of mitral stenosis is "a murmur preceding the systole and ending with its commencement."

It is my habit to examine the heart of nearly every one coming under my care, no matter what the character of the illness, but I have not yet met with a case presenting the mitral presystolic murmur, the heart of which was examined after death, that did not reveal mitral obstruction.

I have found the mitral presystolic murmur to vary much in loudness from time to time, but I do not think I can name a single instance of the entire absence of this murmur after it had become fully developed, except during the conditions mentioned by Hayden.

THRILL.—The fremitus or purring thrill of mitral stenosis is best felt in the fourth intercostal space and immediate neighborhood of the apex beat. It is distinctly presystolic, differing widely from the extremely rare thrill of mitral insufficiency, the latter always being systolic. Fother-

gill states, "the thrill is often absent, but when present, is of great diagnostic value, and marks the case as one of stenosis." ("The Heart and its Diseases," Fothergill). Hayden observes, the thrill "is frequently absent when murmur announces, in the most positive manner, that mitral narrowing actually exists. Out of the total of eighty-one cases, it was present only in forty-one instances; and of the fifteen cases in which death occurred, and the body was examined, it was noted in six only." ("Diseases of the Heart and Aorta," Hayden). The fremitus of mitral narrowing is sometimes simulated by a pericardial friction fremitus, but a mistake in diagnosis may be avoided if proper precautions are observed.

Other physical signs may be present to aid in the diagnosis, but if thrill and murmur are both absent, they are rarely of sufficient value to establish the diagnosis of mitral stenosis.

The first sound of the heart is shortened, intensified and frequently reduplicated; the second sound is feeble or absent at apex, but intensified at left base. (Dr. James Andrew, *vide* the "Heart and its Diseases," by Fothergill). It should be borne in mind that the pulmonary second sound becomes very feeble when the right side of the heart dilates sufficiently to admit of tricuspid regurgitation. Signs of dilatation of the left auricle appear comparatively early, and those of enlargement of the right side of the heart later. Pulmonary hemorrhage is more frequent in mitral stenosis than in any other variety of valvular lesion of the left side of the heart. Passive congestion of most of the internal organs takes place late in the disease. The majority of cases of mitral stenosis end in death before general dropsy results.

Prognosis of Mitral Stenosis.—If the prognosis and treatment of mitral valve disease are not modified by differential diagnosis between constrictive and regurgitant lesions, we should scarcely be justified in devoting so great attention to mitral stenosis apart from mitral incompetency. On these points Fothergill speaks with considerable force. "It is," he says, "unfortunate that so much stress is laid at present upon the diagnosis of the two forms of mitral murmur, because the recognition of the exact lesion does not bear much upon either prognosis or treatment, authorities differing as to whether the prognosis of stenosis or regurgitation is worse; and agreeing that in both cases the correct plan of treatment is to build up the right heart by the administration of digitalis, iron, etc. The day of the prominence given

to the presystolic murmur will ere long be over.”

Such an assertion coming from so good authority deserves due consideration, yet, I think, it is too sweeping, and should not be blindly accepted.

Dr. Sansom, of London, thinks it is rare for mitral obstructive lesions to be of so long a duration as some cases of mitral regurgitation.

Dr. Flint says: “A rough presystolic murmur may represent a degree of mitral obstruction which may be tolerated for years.” (*The American Journal of the Medical Sciences*, 1882). Three of his cases have extended over periods of ten, twelve, and fifteen years respectively.

Lesions of the mitral valve, regurgitant and constrictive, may be divided into two classes. The first class should include those lesions that do not materially interfere with the function of the heart; unknown to the patient, are unattended by any special symptoms, and never compromise comfort or life to a great extent, unless an individual whose heart is thus affected, should suffer from some exhausting disease, which may weaken the heart and cause the valve to re-inflame. This form of valvular disease is frequently only accidentally discovered.

The second class includes all those constrictive and regurgitant lesions which cripple the heart and destroy life.

We can the more readily appreciate the relative prognosis of mitral stenosis and regurgitation, by studying the sequential lesions of each form of mitral valve disease. It is unnecessary to bring forward statistics to prove that lesions of the tricuspid valve admitting free regurgitation more speedily result in death than a similar lesion at the mitral orifice. It is the common experience of most physicians who have met with tricuspid regurgitation, to find the cavities of the right side of the heart to enlarge by dilatation and hypertrophy, and blood stasis with pulmonary oedema, and general dropsy, to take place, followed by death in the course of six months to two years.

The sequential lesions of mitral stenosis, as stated by all who have given much study to the subject, and as first pointed out by Dr. Adams about fifteen years before the mitral presystolic murmur was described by Fauvel, are as follows:

When the mitral orifice is sufficiently constricted to decidedly obstruct the flow of blood from the auricle into the ventricle, the auricle is compelled to contract more forcibly to empty itself. At first, slight hypertrophy of the auricle takes place, but its thin wall soon begins to yield to over-distension, and then dilatation out of all proportion to the hypertrophy results. At this stage, when the

weakened and dilated auricle is unable to propel its contents through a small orifice in the time allotted for its systole, the pulmonary circulation begins to suffer, and, in turn, the right ventricle, compelled to contract upon a larger quantity of blood than usual, also begins to enlarge by hypertrophy and dilatation. While the right ventricle is still strong, the left auricle being dilated, the lungs suffer most, hence blood-spitting, cough, dyspnoea on exertion, and liability to take cold on exposure, are well pronounced. This condition of things soon produces lowered vitality, and the right ventricle, in which hypertrophy for a time kept pace with the dilatation, dilates from distension and weakness of its wall, until, at last, tricuspid regurgitation results, followed ultimately, if the unfortunate sufferer live long enough, by general dropsy. The left ventricle, provided no mitral insufficiency coexists, remains nearly normal or slightly atrophies.

The first of the sequential lesions of mitral regurgitation is seen in the left ventricle. This portion of the heart, for a long time, if no undue strain is put upon it, hypertrophies sufficiently to enable it to compensate by its increased power of contraction for the loss of blood through the mitral orifice. As the left ventricular wall is quite thick and strong, compensation is possible so long as the patient is well nourished, and avoids everything that over-works the heart. Loss of compensatory hypertrophy is usually due to over-exertion, mal-nutrition, and depressing influences, resulting in dilatation and degeneration of the ventricular wall. In speaking of mitral valve lesions, Flint observes: “All the symptoms and effects referable to the respiratory system are more marked when the lesions are obstructive than when they are only regurgitant.” (*Diseases of the Heart*.) “Hope remarks that he had met with pulmonary apoplexy more frequently in connection with great contraction of the mitral orifice, with or without hypertrophy of the right ventricle, than in any other association.” (*Diseases of the Heart and Aorta*, Hayden.) In some cases of mitral regurgitation, the lesion is so extensive and the loss of blood so great that it is impossible for compensation to be established by hypertrophy of the left ventricle.

Mitral stenosis and regurgitation existing together make the prognosis more unfavorable than when one of these lesions exists alone. Compensation seems to be better effected in mitral regurgitation when aorta valve lesions

co-exist. It has not been my experience to find the same benefit result from aortic valve disease in mitral stenosis.

Hayden believes that the longer the mitral presystolic murmur the greater the obstruction, and hence the graver the prognosis. It is in such cases that he has found associated the postdiastolic and presystolic murmur.

TREATMENT.—In the few words that I shall devote to the treatment of mitral stenosis, I shall not discuss those measures that seem to me equally efficacious in both mitral obstruction and regurgitation.

Rest in the recumbent posture.—In those cases in which mitral obstruction is giving rise to inconvenience, rest from time to time in the recumbent posture, I have found to aid greatly in relieving the pain and sense of constriction around the heart, symptoms which, as a rule, are more pronounced in mitral constriction than in regurgitation.

Avoiding stimulus.—Total abstinence in many cases may be observed. Irritability of the heart is always well marked late in the disease, and alcohol frequently increases this. If any stimulus is given, it should consist of the lighter wines. This course is applicable to cases of mitral regurgitation, but until late in the disease, does not seem so imperative.

Protecting the body from sudden changes of temperature.—When it is understood, next to the heart, the lungs suffer most from this form of valvular lesion, the importance of preventing chilling of the body will be appreciated. Hæmoptysis, pulmonary apoplexy, or pneumonia, may result from exposure to damp and cold. The chest, especially, should be well clad. As in pulmonary phthisis, a chest-protector should be worn during the cold season of the year.

Local treatment.—This consists of cups, dry or wet, leeches, blisters, and milder counter-irritants, followed by poultices, over the præcordium. Wet cups I have never used. Dry cups over the heart both early and late in the disease, give great relief. It has been my experience to find pericarditis, or pleuro-pericarditis, relatively more, much more, frequently associated with obstructive than with regurgitant lesions at the mitral orifice. It is in such cases that a few leeches over the heart, afford great relief. Local abstraction of blood is very beneficial when the heart is acting tumultuously on account of its cavities being over-distended with blood. Counter-irritants, followed by poultices, afford a sense of comfort.

Special internal medication.—In mitral stenosis

the auricle contracts ordinarily in too short a time to allow sufficient quantity of blood to flow into the ventricle through a narrow mitral orifice. By special medication we desire to slow and tone up the heart's contractile power. Digitalis slows the heart and increases the force of its contraction. It has been the remedy in these cases for a number of years, but to its use objections are not wanting; it frequently disagrees with the stomach, its poisonous effects are feared if we are compelled to continue its use too long, and moreover, some cases of mitral stenosis do not seem to be as favorably influenced by it, as most, if not all, of those of mitral regurgitation. Of late, much has been said and written about the use of convallaria maialis, or majalis, in the treatment of cardiac disease. Some have asserted that this old and new remedy in the treatment of dropsy is more adapted to the treatment of mitral obstruction than to mitral regurgitation. My experience with this agent is limited. The cases in which I have tried it have been desperate, and because I did not get satisfactory results from its use, I do not feel inclined to condemn it. I am glad to know that we shall be favored this morning with the results of Dr. Bruen's experience in the use of convallaria majalis.

In conclusion I may add, from a careful study of mitral stenosis, I have been led to believe: That it is often of some practical importance to diagnose the obstructive from the regurgitant form of mitral lesions; that the prognosis and treatment of mitral valve affections are more or less modified by the fact of whether the lesion be stenotic or regurgitant.

SCARLATINA: THE POSITION OF THE SYMPATHETIC NERVE IN ITS SYMPTOMATOLOGY AND BELLADONNA AS A MEANS OF THERAPEUSIS.

BY HENRY BEATES, JR., M. D.,
Of Philadelphia.

Read before the Northern Medical Association of Philadelphia, March 9, 1883.

(Continued from page 483.)

In scarlatina, as before mentioned, we have vaso-motor paralysis, and, notwithstanding the consequent increased elimination of heat, there is marked augmentation of temperature. Wood has conclusively proven that section of the medulla oblongata at its junction with the pons, results in increased heat elimination, and at the same time increased heat production, the increased heat dissipation not keeping pace with the increased

production, so that bodily temperature rises. Adjusting these facts with the knowledge we possess, that in scarlatina we have vaso-motor paralysis, and, at the same time, increased bodily temperature, it *seems* to be a logical conclusion, that the materies morbi of scarlatina while, paralyzing the vaso-motor centres, at the same time stimulates the caloric centre. This conclusion, while apparently true, is *inadmissible*, because the phenomena of heat increase, pyrexia, are all due to results, in their nature, PARALYTIC!—(I limit this statement to the conditions under consideration)—and we are compelled to admit that pyrexia is dependent upon the removal of an inhibitory influence, which influence is preëminently that of retarding, or rather controlling, chemical changes in the body that result in the production of caloric. Tscheschin, quoted by H. C. Wood, has proven the existence of such a centre. Here looms up the great physiological fact that nutrition, and all that is implied by the term, depends entirely upon the integrity of the nervous system! If we call to mind the manifestations of disturbed and perverted nutrition in scarlatina, and interpret the phenomena of adenitis, gangrene, and sphacelation, so common in the malignant type in which, as it were, the nature of the poison is magnified, we can not err in the conclusion that this disease is a manifestation of a grave *depressing influence* affecting the *nervous system* of organic life, *i. e.*, the sympathetic. When a sensory or afferent nerve is stimulated, a fall of temperature follows, as the influence affects some centre either in or above the pons. This law, enunciated by Prof. Wood (H. C.), it is desired to be especially remembered, as it possesses an important bearing upon the treatment of the disease under consideration; for if a *depressing* poison occasions the phenomena denominated scarlatina by influencing the sympathetic system, a remedy possessed of the power to *stimulate* this system should, when administered in proportion to the degree of intensity of the depressing cause, be capable of reëstablishing functional equilibrium, and dissipating the disease. Within certain limits this is a fact. Hitzig has conclusively proven that a caloric centre is located in the first cerebral convolution immediately behind the sulcus cruciatus. Wood has proven that *destruction* of this region is followed by enormous increase of heat production, and that *stimulation* of it results in marked *diminution* of calorification. This is emphasized!

To briefly state the points, now deemed proven, we have:

1. That heat elimination is controlled by the vaso-motor nervous system.

2. That paralysis of the vaso-motor system results in *marked cutaneous hyperæmia* and increased elimination of caloric.

3. That in scarlatina we have *paralysis* of the *vaso-motor system*, *marked cutaneous hyperæmia*, and increased elimination of caloric, but notwithstanding this, pyrexia.

4. That an inhibitory centre exists, situated either in the frontal cerebral convolution, or pons varolii.

5. That paralysis of this Hitzig centre is followed by enormous increase of heat production.

6. That agents of a depressing nature paralyze the vaso-motor centre, and also the region of Hitzig.

7. Stimulation of the inhibitory centre is followed by diminution of calorification.

8. That in scarlatina we have a poison that paralyzes or greatly curtails the operation of both the vaso-motor and inhibitory centres, and that pyrexia must necessarily, in its peculiar mode, result.

It will be instructive to here quote the conclusions of Prof. H. C. Wood regarding fever:

"1. In health there is in man a fixed mean and a normal variation of temperature, having a regular rhythm, and this variation is beyond the control of all disturbing causes which do not force the organism beyond the condition of health.

2. The maintenance of normal temperature and its rhythm is dependent upon the nervous system, which, within certain limits, controls both the production and dissipation of animal heat.

3. So far as our present knowledge goes, the chief factor in controlling heat dissipation is the vaso-motor nerves, including, in man, such nerves as control sweat secretions; these nerves being able, by contracting the capillaries of the surface of the body, and by drying the secretion of the skin, to reduce the loss of heat to a minimum, and by a reverse action to increase it to a maximum.

4. The only nerve centre proven to exist capable of influencing the heat production without affecting the general circulation is situated in the pons or above it, and whilst it may be a muscular-vaso-motor centre, it is more probably an inhibitory heat centre. Of whichever nature it may be, it must act through subordinate centres, situated in the spinal cord.

5. Fever is a nutritive disturbance in which there is elevation of the bodily temperature, and also an increase of the production of heat by an increase of the chemical movements in the ac-

accumulated material of the body; this increase being sometimes insufficient to compensate for the loss of that heat which is derived directly from the destruction of the surplus food in the body, very little or no food being taken in severe fever. The rise of temperature in fever, is, therefore, not dependent altogether upon heat production, as in fever there certainly is sometimes less production of heat in the organism than there is at other times when the bodily temperature remains normal; also excessive heat production may occur even at the expense of the accumulated materials of the organism without elevation of the bodily temperature.

6. In fever a daily temperature variation occurs which is parallel to that seen in health, and differs from the normal variation only in having a higher mean.

7. In fever vaso-motor paralysis when produced is followed by an immediate fall of temperature, similar to but greater than that which is produced by a like disturbance in health.

8. The decrease of heat production which follows section of the cord is much greater in the fevered than in the normal animal.

9. The so called inhibitory heat nervous system is not paralyzed in fever, but is less capable than in health of answering promptly and powerfully to suitable stimuli. In other words, it is in a condition of paresis or partial palsy.

10. The clinical succession and phenomena of a febrile paroxysm, such as that of an intermittent, seem plainly to depend upon the nervous system for their arrangement and relation.

11. In most cases of fever, and probably in all cases of serious fever, there is a definite poison circulating in the blood, the poison having been found in the system, sometimes having entered the organism from without. Bearing these facts in mind, the theory of the causation of fever becomes, to my mind, at least, very plain. It is simply a state in which a *depressing* poison, or a *depressing* peripheral irritation, acts upon the *nervous system*, which regulates heat production and dissipation. Owing to its depressed, benumbed state, the inhibitory centre does not exert its normal influence upon the system, and consequently tissue change goes on at a rate which results in production of more heat than normal, and an abnormal destruction and elimination of the materials of the tissue. At the same time the vaso-motor and other heat-dissipating centres are so benumbed that they are not called into action by their normal stimulus, pyrexia, and do not provide for the throwing off the animal heat until it

becomes so excessive as to call into action even their benumbed and depressed forces.

Finally, in some cases of sudden and excessive fever, as in one form of the so-called cerebral rheumatism, the enormous and almost instantaneous rise of temperature appears to be due to a complete paralysis of the nervous centres presiding over heat production and dissipation."

This extensive quotation is made in order that our present knowledge of pyrexia may be presented as succinctly as possible, and that the changes produced by experimentation and the phenomena attendant thereon may be compared with those dependent upon the effects of the *materies morbi* of scarlatina. All fevers do not present identical symptoms. Pyrexia, as such, however, accompanies many morbid conditions and processes; but in this special exanthem, the concomitant phenomena are preëminently attendant upon direct depressing influences exerting themselves upon the sympathetic, and the nature of the disease by its specific effect upon the function of this system is clearly shown, and its morbid affinity for this tract demonstrated. That the mode of onset may be clearly indicated, the following extract from my record of cases will be made:

H. W., male, æt. nine years, on December 14, 1882, arose apparently in his accustomed good health. He ate a hearty breakfast, and attended the morning session of school. At dinner he complained of no especial illness, but had no appetite. About 1 p. m. a pronounced epigastric pain developed, which, in a short time, was accompanied with vomiting. Emesis occurred frequently, proving a very distressing symptom. Thirst was insatiable, and every mouthful of water imbibed was promptly vomited. The gastric contractions were forcible and spasmodic. Fever became pronounced, and a marked tendency toward drowsiness developed. He was first seen about 5 p. m. He complained of sore throat. Head symptoms were negative, except mild delirium. Throat presented evidences of hyperæmia. A muscular exanthem was conspicuous upon the velum palati, and the faucial pillars reddened. Temperature, 101°; respirations, 23; pulse, 96. The slowness of pulse for the degree of pyrexia occasioned some doubt whether I was dealing with a probably co-existent diphtheria, but scarlatina, however, was diagnosed, and treatment instituted accordingly.

December 15th, 9 a. m. Vomiting continued throughout the night until 2 a. m., then ceased until 7, when it recurred. An intense development of the characteristic exanthem had occurred,

being especially marked over the back. Angina troublesome. Epithelium of tonsils elevated by a subepithelial purulent-looking exudate. Pain during deglutition, severe. Temperature only 102.4: pulse 126, respirations 24. Delirium had continued throughout the night, and at times occurs this a. m. Gastric irritability still present. Thirst not so troublesome. 5 p. m. Emesis less frequent. Diarrhœa amounting to eleven evacuations of a watery or paralytic character. Epigastric pain (solar plexus) diminished. Angina more severe. Delirium not so marked. Temperature 105, respiration 28, pulse 148—numbness of hands.

December 16th, 10 a. m. Temperature 103.4, pulse 122, respiration 22. Slight cough. Pulmonary signs negative. Subjectively, angina is worse, objectively better. Emesis has ceased and diarrhœa diminishing. 6 p. m. Temperature 104.2, pulse 126, respiration 22.

December 17th, 9:30 a. m. Less delirium, past night. Considerable sleep. Angina much less troublesome. Temperature 101.7, pulse 120, weak, and degree of compressibility varying. 7 p. m. Temperature 103, pulse 108, respiration 20. Cough worse; angina notably less. Has noticed surrounding objects and asked for food. Only seven evacuations in twenty-four hours. Exanthem fading and convalescence entered upon. Complains of itching. From this date improvement continued until the present, when he is perfectly well. Aural pain, at the height of the attack, was such as to cause apprehension of suppurative inflammation. Desquamative nephritis and renal dropsy were marked, but now the urine is free from both albumen and casts; several examinations for a period of many weeks failing to detect either. Hearing same as before attack.

The effect of belladonna, when administered in a sufficiently large dose, is to engender dryness of mouth and pharynx, angina, pyrexia, delirium, convulsions, and coma. The pulse is accelerated, and reaches even 160 or more. Small doses are followed by rise of arterial pressure. This, of course, obtains before paralysis of the sympathetic occurs. Large doses occasion increased pulse rate and diminished blood pressure; the increased rate being due to paralysis of the peripheral inhibitory nerves and stimulation of the accelerators, *i. e.*, sympathetic, the diminution of pressure to vaso-motor paralysis. The duplex of belladonna in causing in a small dose rise of arterial pressure is due to stimulation; fall, to paralysis. Upon the nervous system this duplex action is still apparent—thus small doses produce delirium (stimula-

tion), large doses convulsions and coma (paralysis).

Minute study of the effects of belladonna demonstrates the fact that of the sympathetic ganglia some are more susceptible to its influence than others; or in other words, belladonna affects certain ganglia powerfully, while others are but slightly influenced. This is especially noticeable in the superior cervical ganglia and by intercommunications and a practical continuity of structure, the ophthalmic ganglion. The same fact obtains in the materies morbi of scarlatina! The former, however, acts by stimulation, the latter by depression.

Scarlatinal poison in sufficient quantity to affect the vaso-motor system curtails the power of the inhibitory area of Hitzig; belladonna in same proportion stimulates it.

From these facts it seems to me to be clearly proven that when we endeavor to meet a depressing agent that affects the same tract by depression as belladonna does by stimulation, we possess the rational method of treating this direful disease. That concomitant conditions arise and demand special treatment need scarcely be mentioned: our judgment and skill must serve for this issue.

ABSCCESS, ULCERATION AND NECROSIS AS MET WITH IN THE NASAL CHAMBERS.

BY HARRISON ALLEN, M. D.,

Professor of Physiology in the University of Pennsylvania.

Abscess, ulceration and necrosis, as met with in the nasal chambers, present peculiarities which are sufficiently marked to warrant their consideration separately from their occurrence in other parts of the body. As compared to other affections of the nose, they are less frequently seen than is generally supposed, and may on the whole, be grouped among the rare disorders. The following essay is based entirely upon personal observation, and claims to be nothing more than a brief summary of signs, symptoms, diagnosis and treatment.

Nasal Abscess.

Collections of pus in the walls of the nasal chambers are due to furuncle, or to causes connected with disease, either of the jaws or of the teeth.

Abscess of the vestibule, or nasal furuncle, commonly forms about the sebaceous follicles and roots of the seta-like hairs of the nostril at the junction of the ala and the floor. It rapidly develops, and is matured by the third or fourth

day, at which time it forms a rounded sessile elevation at the floor of the vestibule, causing more or less redness and distortion of the nasal wing. The abscess infrequently tends to point outward upon the face. Should the abscess open spontaneously, the pus is observed to be of a thick consistence, and after its escape to leave the abscess wall foul and shreddy. This appearance subsides in a few days and a cure is effected.

Accompanying the development of the abscess there is presented more or less swelling of the corresponding side of the face. Acute pain is felt at the root of the nose, and the angular vein between the internal canthus and the nose is often distended.

Diagnosis.—In the initial stage, before swelling occurs, the pain along the nose and the face simulates, and may be confounded with the pain of neuralgia, especially that of the supra-orbital form. If there is no tumefaction at the nostril, it is difficult to distinguish between the two conditions, since, as has been stated, the pain may be referred to a point remote from the inflammatory focus. The absence of involvement of any branches of the fifth or the seventh nerve, and the announcement of facial and alar tumefaction soon decide the question. In the stage of facial swelling, the general appearance of the parts is identical with that in *alveolar abscess*. Indeed, the two arise from the same cause, namely, œdema and inflammation of the subcutaneous connective tissue. Careful examination of the teeth and gums will easily determine the origin of the swelling. From purulent or cystic disease of the maxillary sinus, vestibular abscess is separated by the acute character of the attack, and by the fact that the canine fossa, which is easily reached by placing the finger above the gum line to the outer side of the eminence of the root of the canine tooth, remains unchanged in the case of nasal abscess, while it is obliterated or has its depression converted into a rounded swelling, in the case of purulent or cystic maxillary disease. Even after the swelling of the suspected abscess is recognized, the differentiation between it and *facial carbuncle* should be carefully made. If pus is not freely formed by the fourth day, or if more than one point of suppuration be detected, or if the inflammatory swelling about the nostril becomes diffused and brawny, or if, in addition to these signs, the angular vein becomes prominent and tortuous, the lower eyelid dusky, and the eye suffused, the diagnosis of facial carbuncle can be made.

Treatment.—The swelling should be freely in-

cised from *within the vestibule* whether pus be present or not. The possibility that the suspected abscess may be the first stage of facial carbuncle can in this way be met, at the same time that the indication for the abscess itself is provided for. In many cases the trouble is insignificant, and requires but little care. In others, on the contrary, where great distress, loss of sleep, and disfiguration are present, rest in bed, the administration of opiates and febrifuges, in addition to the local incision, are demanded. In such cases, as soon as the acute symptoms have subsided, quinia in tonic doses may be given with propriety.

In nasal abscess, other than furunculous, the prodromata are analogous to those of bone or dental disease. Pus may escape into the nasal chamber from an alveolar abscess, though this is an infrequent occurrence. In a case coming under the writer's care, the condition named simulated chronic nasal catarrh of the inflammatory type, and was only distinguished from it by a careful study of the discharge, which, instead of being muco-purulent, consisted of pus mixed with normal mucus. Pus may be confined in a sac of mucous membrane, lying at the floor of the nasal chamber. In a case of this kind occurring in a middle-aged woman, the collection had persisted for fifteen years, had been three times punctured, and had been diagnosed as a cyst of the superior maxilla. The writer opened the cavity along its entire upper surface, and, guided by the direction of a curved probe, which passed toward the mouth, he secured drainage through an opening made between the upper lip and the gum line of the upper jaw. The condition was entirely cured within a fortnight.

Nasal Ulcerations.

Ulcerations in the nasal chamber are of two kinds, septal and turbinal.

Septal ulcerations are in like manner of two kinds, those confined to the mucous membrane and those involving either bone or cartilage.

Ulcers of the mucous membrane.—These are confined for the most part to the mucous membrane covering the triangular cartilage. They are rounded, superficial patches, covered with small blood clots, and thin amber-color crusts. Soreness and dryness of the nose are the principal symptoms complained of, to which may be added occasional bleeding. The edges of the ulcers are not elevated, nor is the general surface depressed. Septal ulceration rarely exists independently and is probably often a sequel of irritation in the turbinal plates. The most obstinate form of ulceration is found in individuals with thin aquiline

noses and narrow nostrils, who are annoyed by a constant sense of irritation in the vestibule. To relieve this, the nostril is constantly wiped with the handkerchief, with the result of exciting a hyperemia of the parts, which naturally extends to the septal cartilage, and this in turn being the least highly organized of the nasal structures, is apt to become diseased.

This view of the etiology of these cases need not be modified by the fact that the patches are often found on the upper and back part of the triangular cartilage, at a point out of reach of the finger or the handkerchief, since pressure against the cartilage at any point can readily induce congestion throughout its entire extent.

One form of septal ulceration is found only on the maxillary spur, and is the result of picking the nose to remove the crusts accumulated in an unventilated vestibule. The presence of septal ulceration is easily detected by examination through the nostrils. A crust or clot may obscure the exposed patch, but after such coverings have been removed, the characteristic appearances are detected.

The Treatment of the condition is based primarily upon the removal of the catarrhal states on which it depends. The ulcers themselves should be thoroughly wiped with the solid nitrate of silver, or with a saturated solution of the same salt, and the chamber should be closed by the insertion of a pledget of cotton in the nostril. Should these applications fail after two or three trials, a pledget of cotton of sufficient size to occlude the respiratory portion of the nasal chamber should be inserted back of the ulcer. Iodoform should then be packed liberally in the space in front, until the ulcer is entirely covered, after which a second pledget of cotton is placed in the nostril. Should much hyperæsthesia exist, a sixth of a grain of morphia may be added to the iodoform. This application may be repeated every third day. No difficulty need be experienced, as a rule, in curing the ulcers, provided the air about the patient is healthful. A rarefied air, an air charged with alkaline dust, or the air of a furnace-heated house, will sometimes successfully combat all efforts to cure this disease. The writer has known the ulcers to recur after entire recovery, upon the patient's removal to a mountainous country or to the alkali plains of the West. As to furnace-heat, it is perhaps no more irritating to septal ulceration than to any other form of nasal disease, but it is a constantly present factor of interference. The constant use of the nostril pledget can be recommended where a tendency to recurrence of the disease exists.

Septal Ulcers involving Bone or Cartilage.—In a more aggravated form than the one last mentioned, nasal ulceration may exist as a superficial bone-ulcer in the posterior and inferior borders of an opening due to a congenital defect in the septum. Occasionally it is found upon the sides of a perfect septum, either above, near the roof of the vestibule, or more frequently at the floor, near the maxillary spur. In the rare cases of chronic syphilitic disease without necrosis, the ulcer may be serpiginous, and disposed on both the right and the left surface of the septum. The symptoms are almost identical with those of other ulcerations of the mucous membranes.

A tendency to moderate epistaxis is a constant symptom if septal ulceration exists. The parts are, as a rule, covered with a thin dry clot mixed with the crust of inspissated serum. The habit of picking the nose to remove these crusts is early acquired, and to it must be assigned an important role in the prevention of recovery.

The treatment of the condition consists in freely cauterizing the ulcerated surfaces with the galvano-cautery, and after the eschars are removed, in touching the new surfaces with solid nitrate of silver. A cure can be anticipated from the use of these measures, if no specific taint be present.

The congenital septal perforations have been seen by the writer in two places only; namely, in the triangular cartilage directly in front of the junction of the perpendicular plate of the ethmoid bone and the vomer, and in the substance of the perpendicular plate of the ethmoid. They may exist without the knowledge of the individuals possessing them, who report for treatment only when the edges become ulcerated.

In an interesting case referred to the writer by Dr. Albert H. Smith, the edges of a large opening of the kind described, were found to be ulcerated. The idea of the opening being congenital was vehemently combated by the patient, who was thirty years of age, and had suffered but three years with the symptoms of ulceration. The question was then asked, how can congenital openings be distinguished from the acquired ones. The answer satisfied the patient, and may serve to satisfy others making similar inquiry. The acquired perforations are always syphilitic, and co-exist with other signs and symptoms of this disease. Congenital perforations will be found to be associated with other minor congenital defects, for this is the law. In the case referred to attention was directed to the asymmetry of the rugæ of the hard palate, to the unusual elevation of the hard palate, and to the presence of an ex-

ostosis on the line of the inter-palatal suture. In a case of acquired perforation in a person suffering from tertiary syphilis the nasal chambers were found plugged with enormous quantities of inspissated mucus, which occasionally become detached in masses of considerable size, and passing into the pharynx produced most distressing stridor and asthmatic excitement. Removal of the collections gave only temporary relief, and owing to the existence of the opening, plugging either of the nostrils was impracticable. It then occurred to the writer, after the borders of the opening were healed, to insert a vulcanite plate in the opening of the septum. This was skillfully done by Dr. Ed. C. Kirke, a dental practitioner of Philadelphia, and the patient, by the aid of a cotton plug in the nostril, was enabled to close one side of the nose, and thus give the parts rest and prevent the inspissation taking place. By alternating the use of the plug in the right and the left nostril, both chambers were kept free from inspissated mucus, and the patient became almost entirely relieved. The vulcanite plate has now been worn continuously for eighteen months with the greatest possible comfort.

Turbinal ulceration is of much rarer occurrence than septal, and apart from the mention of its occasional syphilitic origin does not demand special consideration. The best marked example of the last-named variety the writer has seen was located on the anterior extremity of the left middle turbinated plate, and was associated with excessive discharge of muco-pus. The external nose was reddened. The ulcer was depressed and vascular, but without pain. Recovery was secured after a treatment of six weeks. In addition to the administration of iodide of potassium and corrosive sublimate, the ulcer was repeatedly touched with the acid nitrate of mercury.

Necrosis.

Necrosis of the bones entering into the nasal chambers occurs in two forms. The most common of these (although relatively rare as compared with other nasal diseases) is an exfoliation from the base of a bone ulcer. It is seen in cases in which the pus from a diseased frontal or diseased maxillary sinus flows over the turbinated bones. The exposure of the bone surface must be, therefore, considered as a sequel of grave bone degeneration elsewhere. The second form is specific necrosis of the septum, turbinated bones, and superior maxilla. In profound changes in the facial structures large masses of these bones may be lost. In the varieties of this form of necrosis met with by the writer the septum has been more frequently

involved than the turbinals or the maxilla. The treatment of these cases is simple, for in addition to the administration of anti-syphilitic remedies, nothing is demanded beyond the removal by the forceps of the portions of dead bone if they are detached, or the drilling away of the dead portions if they remain attached to the living tissues. Although complete recovery cannot be anticipated, the purulent discharge and the intensely offensive odor accompanying the presence of dead bone in the nasal chambers can be corrected.

HOSPITAL REPORTS.

CLINICAL LECTURE.

BY E. G. JANEWAY, M. D.,

Professor of Diseases of the Nervous System and Clinical Medicine, Bellevue Hospital Medical College, New York.

GENTLEMEN: I again present you the young man whom you saw last week, suffering from paroxysms of the respiratory muscles. You will observe that his condition is greatly improved to-day. He says he had but two attacks yesterday, and only one to-day. The treatment had consisted in the administration of arsenic and the use of the galvanic current, but as he did not seem to improve, atropia was substituted in doses of one-seventieth of a grain three times a day, with instructions to increase the amount if necessary. Patients sometimes become accustomed to the use of atropia, and in order to keep up its effects it is necessary to increase the dose. I had an illustration of this fact in the case of an epileptic patient, who had frequently recurring paroxysms, and had been treated by various means, as the taking of nitro-glycerin, nitrite of amyl, the bromides, etc., but without benefit. I advised the discontinuance of these, with the substitution of atropin in about one-sixtieth grain doses. He commenced to improve, but in order to keep up the beneficial effects of the drug, it became necessary to increase the dose as high as one-twentieth of a grain, which amount he is taking at present.

In the case of empyema shown at a previous clinic, and in which a free opening was made, the granulations at the edge of the wound afterward became sloughing, pus was discharged, the temperature rose to 103° F., and the case was beginning to present a very unfavorable aspect. Carbolic acid solution, however, was substituted for the boracic, an iodoform dressing was applied to the wound, and the temperature fell yesterday to 99°.

You will remember that it was my intention at the last clinic to show you a patient in illustration of a certain affection, but it so happened that I was unable to present more than a *post mortem* specimen. By bearing in mind the anatomical features of the specimen then presented, and putting them alongside the clinical history of the

case I shall now bring before you, a valuable lesson may be impressed. This man is an Italian who speaks no English, and the facts in his case are to be derived chiefly from a physical examination. He is thirty-three years of age, and it appears that eleven years ago he had syphilis. As he lies upon the cot, the first thing which strikes your attention is a pulsation observed just below the apex of the heart, and one near the cardiac extremity of the stomach. This pulsation becomes more apparent at a distance by bending pieces of paper a few inches in length at a right angle, and placing one upon either point at which the pulsation is observed, when the perpendicular arms move through an observable space, and in this case nearly synchronously, though not absolutely so. This pulsation is also observable on the left side over the back, on a line corresponding with the pulsation in front. There is some dulness in front, but not such as could not be accounted for by the possible presence of the left lobe of the liver. The patient complains of pain principally on the left side, extending from the back round to the front, in the region of the lower intercostal spaces. It does not extend below the last dorsal vertebra. The tumor, as I have already suggested, is an aneurism, and its location is pretty nearly determined by the region of pain, namely, in the lower part of the thoracic aorta. The pain from which he suffers is doubtless caused in this case, as in the other case, by pressure of the aneurism upon and erosion of the vertebrae, from which the intercostal nerves find exit. I listen for a murmur in this region, but none can be heard while he is lying down. When he sits up, however, a systolic murmur can be heard in front, just below the ensiform cartilage.

Now, I have brought this patient before you on account of the possibility of mistake in the diagnosis. Three conditions might very well suggest themselves as the possible explanation of this case, and it would appear that treatment had been adopted before the patient's entrance into the hospital, pointing at that time to an incorrect diagnosis. The chief subjective symptom from which the man complains is that of intercostal neuralgia, for which in the absence of a careful physical examination the case might be mistaken. Again, Pott's disease would produce very much the same symptoms that we have here, and, moreover, there is another fact which would tend to strengthen the suspicion that such was the affection from which he was suffering, namely, a prominence of a vertebra, corresponding to about the tenth dorsal. You will also observe that as the patient attempts to pick up something from the floor, he avoids bending the spinal column in this region, and allows flexure only at the hip and knee. But, against the view that the case is one of Pott's disease, we find upon careful physical examination a murmur and pulsation which point distinctly to an aneurism. The difficulty of diagnosis between Pott's disease and aneurism in some instances was illustrated in a case in the hospital a good many years ago, in which before admittance a diagnosis of lumbago had been made, and after admittance that of Pott's disease, and the day before the fatal termination of the case, a professor in

one of the colleges made use of it as a text for a clinical lecture upon Pott's disease. The following day, while the patient was picking a chicken bone, he suddenly collapsed, and the pleural cavity at the autopsy was found full of blood, due to rupture of an aneurism of the aorta.

As regards treatment, iodide of potassium and slowing of the circulation. The prognosis in these cases of aneurism is, of course, unfavorable. There are but few hopes that a case of aneurism will end in recovery—even if a firm clot should form within the sac. You will remember how the aneurism shown you last week was protected by a firm clot on one side, but that did not save the patient. The general tendency, therefore, is toward rupture and death from hæmorrhage. It is probable that in this case, as in the former case shown you, the hæmorrhage will take place, when it occurs, into the pleural cavity. But we may, perhaps, accomplish some good by iodide of potassium and quiet. I have also found gelsemium in some cases to work very well, as well because of its pain killing character as because of its heart quieting character. The house physician tells me he carried out the idea of gelsemium, but the heart became weak under its influence, and we will now try digitalis instead. Now, digitalis theoretically ought to be bad for aneurism. But I have seen it practically do a great deal of good, and a clot form under its influence, although, of course, a permanent cure was not expected to take place.

I will now present you three male patients, born in Turkey, Arabia, and Bohemia respectively, and whose history on account of their foreign tongue has been but imperfectly obtained.

The appearance of the first patient, the Turk, itself speaks largely for the diagnosis of the case. Notwithstanding his naturally dark skin, it is evident that he is anæmic—anæmic to such a degree as to suggest the idea of leucocythemia; and it was my intention to compare this case this afternoon with one of that disease, had the patient not failed to come. You will observe that the back of the hands are pale, the lips are pale, the tongue is pale, and the conjunctivæ are pearlsh. On microscopic examination of the blood, there is found to be decided diminution of the red blood globules, with perhaps a slight increase of the white. Compared with that of one of your number who is in robust health, you will observe a difference in its appearance upon the slide even to the naked eye.

Now, there are two or three things which may be the cause of the anæmia, and which should be borne in mind in any given case. One is, a cancerous process, or any cachectic process, as phthisis, which might by protracted suppuration produce a condition of anæmia. But then the patient is more markedly anæmic than almost any phthisical patient in my wards, and other signs of that disease are absent; nor is there any evidence of cancer. The loss of blood by vomiting, by hæmorrhoids, by bleeding sores, or other means, would account for it, but there is no history of anything of the kind. An examination of the urine shows that he is passing a large quantity daily, the specific gravity is 1010, and quite

a small quantity of albumen was found, but no casts. This might signify chronic nephritis, usually the small contracted kidney, although in a great many cases of the small contracted kidney there is no such anæmia as is seen in this patient. The fact, therefore, that the man has chronic nephritis does not explain altogether his anæmia. Being a Turk, and therefore probably having lived near or in Egypt, we should think of the possibility of an anæmia sometimes seen in inhabitants of that or neighboring lands, due to a small parasite that abstracts blood in the duodenum. But we have no proof of the presence of such a parasite in this case, and that possibility may be set aside. When we consider the kidney trouble, we may say that the anæmia is out of proportion thereto, and I think that in the light of the evidence before us we may look upon the case as one of pernicious anæmia complicating chronic nephritis.

The case of the Bohemian is interesting simply as showing the possibility of mistaking certain dark spots upon the body due to filth for the signs of commencing Addison's disease. The question arose in his case whether the appearances of the skin upon certain portions of the body were not indicative of that disease, but upon further inquiry into his history we learn that he has been a tramp, has been exposed to the weather, is not cleanly, and has doubtless had body lice, which have caused him to scratch in the localities referred to.

The Arabian presented some symptoms which led us to suspect the possibility of a grave form of anæmia, but by rest and care in the hospital, he has become much stronger, and we infer that his anæmic condition was only temporary, due to privation. The three cases afford a good opportunity to study the appearances of an anæmic condition in the dark races.

EDITORIAL DEPARTMENT.

PERISCOPE.

Phtheriasis Pubis.

In the *Med. Times and Gaz.*, Dr. McCall Anderson says this hairy parasite is met with on all hairy parts except the head, but the hair on the pubis and neighboring parts is its favorite hunting-ground. It is indeed a very curious circumstance that these three varieties of lice should live in such close proximity, and yet in no case leave their own preserves for the purpose of poaching on those of their neighbors—a trait worthy of imitation by the human species. We can understand how one parasite should prefer hairy, and another non-hairy parts; but it is difficult to see how one pediculus should find its appropriate soil on the head alone, while another attacks all hairy parts except the head. Mr. Quekett's explanation is that the crab-louse, owing to the peculiar shape of its claws, is unable to climb up straight hairs to deposit its eggs, and accordingly selects parts where the hair is curly; but, if so, why should we not encounter it on the heads of curly-headed persons?

Character of the Parasite.—The *Pediculus pubis* resembles the head-louse in many respects, but its body is much broader and shield-shaped, and there is no distinct separation between the thorax and abdomen. It is studded with small spines, and, besides possessing six feet which resemble those of the other pediculi, it is furnished with eight rudimentary-looking ones, which terminate in bundles of hairs. It does not run about like the head-louse, but grasps the hairs where they emerge from the skin with its forelegs, so that it is very apt to be overlooked, and some difficulty is experienced in extricating it. The nits resemble those of the head-louse, and are attached to the hair in the same way as theirs, but always close to the exit of the hair from the skin.

The itching leads to scratching, and often small papules are developed, which are red and excoriated; and occasionally an eczematous eruption is induced, the cause of which may be suspected from its situation. An examination will then lead to the discovery of the pediculi lying in close contact with the skin, and of their nits, as well as of reddish particles of fecal matter in the immediate vicinity of the parasites. This affection is met with among all classes of the community, but almost always in adults who have contracted it from others laboring under the disease as the result of impure intercourse, or through the medium of the water-closet.

Diagnosis.—The following points serve to distinguish phtheriasis pubes from simple pruritis:

- | | |
|---|---|
| <i>Pruritis.</i> | <i>Phtheriasis Pubis.</i> |
| 1. Not contagious. | 1. Contagious. |
| 2. No parasite to be discovered. | 2. Lice, their nits and fæces, discovered among the roots of the hairs. |
| 3. May affect other regions, though not necessarily. | 3. Limited to the pubis or neighboring parts, or to other parts provided with hair (always excepting the head). |
| 4. Often a very troublesome affection, and requiring constitutional as well as local treatment. | 4. Readily cured by local treatment, <i>e. g.</i> , a lotion of perchloride of mercury (gr. ij. to ʒj.) |

Eczema complicating Phtheriasis pubis is distinguished from simple eczema by the localization of the eruption, and by the discovery of the pediculi, their nits, and fæces.

The *Acanthia lectularia*, or common bed-bug, remarkable for its reddish color, roundish, flattened form, and offensive odor, resides partly amongst

the bed and body clothing, but principally in crevices in the woodwork of beds, walls, etc., where it deposits its eggs, and whence it sallies forth to feed upon the blood of its victims. It seems not to be met with in South America, Australia, or Polynesia, but is too common in this country in the habitations of the poor, and it is difficult to extirpate it, because it can resist extreme degrees of cold, can live without food even for a year, and hides itself by day.

Its bite produces a swelling like a spot of nettle-rash, but it is distinguished from it by the discovery of the bite in the centre, which, unlike the surrounding redness, does not disappear on pressure. The irritation of the bite, too, as well as the crawling of the parasite upon the surface, is apt to excite nettle-rash over the whole body, which diminishes or disappears by day to reappear at night. The itching is great, and the scratching proportionately vicious, "as the wheals," says Kaposi, "are very large; the two or three middle fingers of the hand are used in scratching, so that the excoriations are apt to be characterized by two or three parallel stripes."

This eruption may be mistaken for that of idiopathic Urticaria (nettle-rash), but in the former the nettle-rash disappears or moderates by day. The bites of the parasites are to be found in the centres of some of the nettle-rash spots, the itching is more intense, and the excoriations are apt to present the characters just mentioned, while a search for the offender will usually clear up the mystery.

The *Pulex irritans*, or common flea, is smaller than the bug; it "is short, shield-shaped, formed of one piece," and its bite is effected by means of "a bristle-like tongue, which is covered by two maxillæ of the form of two sword-blades" (Küchenmeister). The power and elasticity of its feet are very remarkable, enabling it to leap about two hundred times the length of its body, and thus to elude the attempts of its victims to entrap it. Its eggs are about one-third of a line in length, are oval, and of a white color, and are deposited "indifferently on dust and on furniture, and in dirty people under the nails" (Kaposi). It is not so particular as the bug as to climate, although it is said to be unknown in Australia.

Its bite does not produce itching, but it causes a minute hemorrhage surrounded by a bright red inflammatory areola with some swelling; the latter disappears on pressure, but the former does not. The minute hemorrhage passes through the same stages as that resulting from a bruise, and disappears much more slowly than the areola. If the skin is very delicate, as in the case of children, an eruption of nettle-rash may make its appearance, and in that case itching is present. The hemorrhages produced by the bites of the parasite may be mistaken for spots of purpura, from which they may be distinguished by attention to the following points:

Bites of the Pulex irritans (common flea).

1. Fleas, or their dark brown feces, detected on the bedding.

2. Hemorrhages surrounded at first by inflammatory areola.

Purpura spots.

1. Not present.

2. Not so.

3. Spots of uniform size.

4. Specially met with where the clothes closely embrace the body.

3. Not of uniform size.

4. Not so.

The *Acarus folliculorum* was discovered by Henlé in 1841, in the ceruminous, and by Gustav Simon in 1842 in the sebaceous glands. Considerable variations are observed in their size and shape, as well as in the number of their legs—variations which are supposed to represent different stages of development. Even ten or more are sometimes to be discovered in one sebaceous or hair follicle; they lie for the most part lengthwise in the midst of the sebaceous matter, near the surface, and with their heads directed inwards. They are easily detected by squeezing out the contents of the follicle—although they are not found in every one—adding a little glycerine, and examining with a low power of the microscope. They are to be found in the follicles of almost all persons, are not specially associated with any disease, and do not give rise to any symptoms whatever.

Persistent Hiccough.

Dr. James Weaver writes to the *Lancet*, April 7, 1883, the following further particulars concerning his case of persistent hiccough, which we noted some time since:

My patient died on March 13, worn out and exhausted, but otherwise to the last free from an ache or pain, and, with the exception of increased dullness over the posterior portion of the left lung, the symptoms remained almost stationary from the first. When I was called in to see Mr. S—, on the 18th of December, 1882, I found that it was evidently a case of broncho-pneumonia, complicated with hiccough, the latter arising from some unexplained cause. He told me that he had had hiccough more or less since the previous July. He was seen a few days later in consultation, and, although the hiccough was very troublesome, our efforts were chiefly directed to the bronchitis, looking upon the former as a troublesome complication which would soon subside. It did not, however, subside, but went steadily on to the day of his death. On the first of January he was again seen in consultation, and the hiccough was so violent and exhausting that our treatment was somewhat reversed by the remedies for hiccough being brought to the front. It, however, never left him. He was conscious, save an occasional rambling, up to a few hours of his death, and from a state of great mental excitement and anxiety he became perfectly calm and resigned. He slept but very little, and at prolonged intervals, during the whole of his illness, never more than two hours at a time, and was often for days without any sleep. Morphia, chloral, bromide of potassium, ether, etc., only seemed to excite the brain almost to frenzy. The only remedy that did any good in my case was chloroform. I gave it in ten to twenty drops on sugar. I injected it hypodermically with and without atropia, and my patient inhaled it frequently in twenty to thirty drop doses. Some days before the end the patient would occasionally, with great difficulty, raise some thick, very offensive, pus-like matter, streaked with blood.

On March 14, I made a *post mortem* examination. The right lung was much enlarged, and filled not only its proper position, but also extended into the left side of the chest, and so peculiar was the formation that the gentleman who assisted me, at the first glance, exclaimed that there was only one lung. The left lung was so collapsed and solid, like liver, and lying so closely at the posterior part of the chest, that it was completely out of sight. In the right lung there was evidence of diffused bronchitis, and on removing the heart and left lung I became aware of a large mass of scirrhus at the root of the latter, in which were imbedded the pulmonary veins and artery, the veins being partially filled up with masses of scirrhus, and the artery compressed and much smaller than usual. The lung itself was small, hard, and hepatized, but had no scirrhus formation in it. On cutting it across, a dark offensive matter oozed out, and the inner portion was evidently in the early stage of gangrene, being soft, dark in color, and highly offensive. The heart was healthy, as were all the other organs; but on the upper and left side of the diaphragm was a patch about three inches in diameter, rough and hard, covered with millet-seed looking bodies. There were also two small bodies on the anterior portion of the liver. The scirrhus tumor would be fairly represented by a medium-sized orange somewhat flattened at each side, and was no doubt the cause of hiccough either by direct irritation of the phrenic nerve or by reflex action of this nerve through the vagus, the latter more probable than the former, for although the mass was in the direct line of both propositions, yet the phrenic may possibly have escaped by being pushed aside, but the vagus must have suffered from the pressure of such a growth. I must leave it to a better pathologist than myself to say how long such a tumor would take to form.

Dr. Matthews Duncan on Sterility.

In the course of the third Gulstonian Lecture, (*Brit. Med. Jour.*), Dr. Duncan observes:

"It is scarcely an exaggeration to say that, in recent practical works on sterility, there is exhibited entire ignorance or entire neglect of the laws of fertility. Every woman from fifteen to forty-five is regarded as likely to breed. If she be sterile, a cure is at once set agoing; and, if a child be not born, the failure is not debited to the nature of the case, but to the want of ingenuity in the doctor. A reputation for curing sterility is spoken of as if it were founded on substantial claims. The prevalent methods for curing sterility are founded on an implied theory that it in most cases arises from impediments in the way of the spermatozoa reaching the ovum. Without sufficient evidence, strictures are assumed to exist, versions and flexions of the womb are held so to distort the interior passage as to prevent progress of the spermatozoa, cervical catarrh is believed to stop them by mechanical obstruction or by chemically poisoning them; and for these real or imagined evils, sterile women are made the subject of treatment. It is the theory of mechanical obstruction that, by its simplicity and directness, has possessed the profession and the public; and, accordingly, many operations and

modifications of operations, and very many instruments, have been devised to do away with the obstruction. The theory has had real rational support in the fact that dysmenorrhœa of a spasmodic kind does, as already shown, frequently accompany the sterility, and in the supposition that the same obstruction which causes sterility by impeding the entrance of semen, causes also dysmenorrhœa by impeding the exit of menstrual blood, or *vice versa*. It has had still more satisfactory support in the observation that the cure of the dysmenorrhœa does occasionally bring with it cure of the sterility.

"The very zeal with which the mechanical theory of sterility has been fostered, and its treatment in many ways pursued, has led to its present decadence, and there is now increased attention paid to other departments of fertility than conception. Especially and justly, the difficulties of naturally starting and healthily continuing pregnancy are brought prominently into view. The mechanical obstruction theory has begun to shrivel, because of the impression produced by the enormous, though inexactly ascertained, proportion of the failures of the attempts to cure founded on it. Even the ignorant sterile women could see that, if this theory of causation were true, there was an easy and plain theory of cure; and they could also see that the failure of the so-called cure was prejudicial to, if not destructive of, the theory. The importance of the difficulties of pregnancy now brought into prominence will, on account of its great reconditeness, be received with no enthusiasm, such as welcomed the obstruction theory; and the physicians who entertain it can offer no such brilliant prospects of cure to their confiding patients. It is, however, a decided step of progress in a subject of great practical importance.

"It is in Germany that this department of sterility has been chiefly studied, and Grünewaldt of St. Petersburg is its best exponent. Recognizing the importance of this work, I take the liberty of using it to show the great incompleteness of even the most advanced accounts of the subject. For Grünewaldt, sterility is truly never a disease, but a symptom of a disease. Nature has, he says, set no limits to female breeding other than the natural changes in the sexual organs that are observed in the senile state. Sterility is one of the most frequently occurring disturbances of function caused by diseases of the female sexual organs. In these views, and in his whole work, it is implied that sterility depends on disease of the sexual organs, including chiefly endometritis, mesometritis, perimetritis, and parametritis. The difficulties of conception, he says, have only a slight importance, compared with the disorders of the more important vital processes of pregnancy, and these disorders affect chiefly the tissues of the uterus."

Eyesight of School Children.

The *Brit. Med. Jour.*, April 28, 1883, says that a lecture on the effect of reading and writing on the eyesight of young children, was recently given at Berne by Professor Pfüger. The lecturer first called attention to the portentous fact that more than one half of 45,000 children lately examined in Germany were found to be suffering

from defective vision. In some schools, the proportion of the short-sighted was as high as seventy to eighty per cent. whilst, in the Heidelberg Gymnasium, every lad in the school had bad eyesight. This lamentable state of things arose from insufficiently lighted school-rooms, bad print, and bad paper, the method of writing in vogue, and ill-contrived desks and forms. The burdening of children with too many lessons, and the consequent restriction of their hours of play, is a still more potent cause of defective vision. In order to solve the vexed question of the influence of German calligraphy on the eyes of those who adopt it, the Government of Württemberg, some time ago, appointed a commission, consisting of three schoolmasters and three physicians, to investigate the matter, and make a report. In the opinion of these gentlemen, the mere writing is least among the causes which unfavorably affect children's eyesight. They found that, while comparatively few children write with their backs bent towards the left, fully eighty per cent. give their back, when writing, a right inclination. The latter position tends to produce a permanent elevation of the right shoulder, and ultimately causes curvature of the spine. In the schools they visited, the commissioners actually found twenty per cent. of the boys, and from thirty to forty per cent. of the girls suffering from more or less pronounced curvatures due to this cause. The difference between the two sexes is probably due to the fact that lads, besides being more energetic in play, are more rationally clad than girl scholars. As to position in writing, the distance between the desk and the eyes ought to be about 25 centimètres (nearly 10 inches); yet it was rarely, indeed, that the commissioners met with any children who could keep their eyes at this distance from the paper. Many of them found it necessary to bring their faces within seven centimètres (2.75 inches) of their copy-books. The general conclusion of the commissioners, as of Professor Pflüger, is that of all the evils enumerated, the worst, and those most in need of reform, are the seats and desks at present in use. The Professor further remarked that only ten per cent. of the children examined were naturally short-sighted, and that, as among wild races defective vision is almost entirely unknown, the trouble in question is peculiar to modern civilization and the existing system of teaching. Professor Pflüger expressed the fear that he was like one crying in the wilderness, the prevailing tendency being to lay on the children of this generation still heavier burdens, and to force their minds to the lasting injury of their bodies.

The Diagnosis of Scarlet Fever.

In the *Brit. Med. Jour.*, April 14, 1883, we find a paper on this subject by Dr. J. Spottiswoode Cameron. The author remarked that it was occasionally very difficult to diagnose this disease. Compulsory attendance at school made it especially desirable to recognize every case. He dwelt upon the several symptoms of vomiting, headache, and early delirium; and insisted, when these were present, on an examination of the throat. Enlarged lymph-glands between the ear and the jaw were often of importance in doubtful

cases. The tongue, if characteristic, was of value, but absence of strawberry-tongue did not necessarily exclude scarlet fever. Sudden high temperature persisting, typhus and smallpox excluded, generally in a child meant scarlet fever. The rash usually appeared not later than the second day, but he gave cases in which it had been delayed to the fourth or fifth days. In a case with a doubtful history, if he found a tongue with a moist, pale red base, smooth, except that its surface was covered with minute, bead-like papillæ, he should strongly suspect scarlatina: this symptom was, perhaps, the least seldom absent of those characteristic of scarlet fever. This tongue might be found weeks after any pyrexia, but disappeared when there had been no pyrexia. There might be scarlet fever almost without fever, without angina, and without rash. In such indefinite cases, the tongue, the state of the skin, and the urine, were important. Passing to the differential discussion of scarlet fever, Dr. Cameron considered the difficulties presented by a case first seen in (1) the initial, (2) the eruptive, (3) the defervescence, and (4) the convalescent stages of the disease, going over the important symptoms *seriatim* in each step, and showing what light each threw on the differential diagnosis. In the initial stage, measles, diphtheria, smallpox, typhus, pneumonia, quinsy, and simple continued fever might cause difficulty. The history of previous illnesses, the acuteness of the symptoms, the course of the temperature, and the state of the throat, were important. Hospital and drain-throats were apt to be asymmetrical. Ulceration was not common at the beginning of a true scarlatinal angina. A sore-throat in a person who had previously had scarlatina might be infective, as in a case quoted; but diagnosis was generally helped by history of exposure. In the eruptive stage, measles, erythema, rôtheln, and even urticaria, might have to be eliminated. In the stage of defervescence, typhoid fever, amongst other diseases, might be mistaken for scarlatina; and in that of desquamation, other febrile symptoms, latent albuminuria, nephritis, and even some skin-diseases, might require to be separated. There was no one sign always present in scarlatina. In doubtful cases, as complete a history of the attack as possible should be obtained; and a percentage of cases would remain in which the only guide to a diagnosis would be a knowledge of the diseased conditions prevalent around.

Congenital Malformation of Both Knee-Joints.

Mr. Hubert Sells, Senior Resident Obstetrician of Guy's Hospital, describes in the *British Medical Journal* the following case of malformation in a new-born infant, very fairly developed:

On looking at the lower limbs, the first thing that struck one was, that the patellæ on both sides were apparently missing, and in their place was, on each limb, a depression. The description of one limb will suffice for both. The movements of the hip-joint were complete. The thigh, instead of being convex, was slightly concave on its anterior aspect. The tibia and fibula were in their normal relative positions. The foot looked forwards naturally, and the ankle-joint was normal. The patella was placed at the back of the

joint instead of in front. In the normal position of the patella was the depression above mentioned, which apparently represented the popliteal space, as the continuation of the femoral artery could be felt pulsating here, and there were some tendons on either side of it, analogous to the ham-string tendons. There was also, running down a little to the inner side of the centre of this space, a strong tendon, which was continued downwards to the head of the tibia, and may have been the representative of the quadriceps extensor tendon. Posteriorly, the patella was rather firmly fixed, nearer the femur than the tibia, in a strong tendon, so that the impression at first was that it (the patella) was attached by osseous tissue to the femur. This idea was, however, dispelled on moving the joint. The movements of the knee-joint were perfect but reversed. The tendon in which the patella was fixed was exactly like the ordinary extensor tendon of the thigh. The artery could not be traced below the head of the tibia. It may, I hope, be seen from the above description, that the leg could be flexed on the thigh anteriorly, as much as it would have been posteriorly in the normal state. When the child was first seen, it had the toes of one foot almost in its mouth, which, of course, it could reach easily without flexing the thigh. The child died on the third day after birth, and, unfortunately, the parents would not consent to a *post mortem* examination.

Chloroform Breath in Gastric Disturbance.

The French correspondent of the *Medical Press* (April 18, 1883,) says:

There is a symptom of gastric disturbance in children which I have never yet seen mentioned in any text-book, French or English, and yet it is almost invariably constant and generally to be met with at the *début* of the affection, so that it may be considered as a sure premonitory sign, I mean that of the breath, which smells as if the child had freely inhaled chloroform. I have always found that this "chloroform breath" not only commenced with the gastric disturbance, but continued during the whole period of the malady, and that its cessation indicated also a cessation in all the other general symptoms, fever, vomiting, etc., and consequently a return to health. I have remarked this peculiar odor in children of every age, and once in a grown-up person; it was then very strongly marked. I do not pretend bringing to light anything new, but I have never heard this peculiar symptom alluded to anywhere. In gastric derangement or *embarras gastrique*, as the French call it, the breath has always been described as possessing a heavy odor, but that is very different from the chloroform smell which is sometimes so pronounced as to be liable to induce the medical man to believe that the patient had been using the anæsthetic.

Another correspondent writes to the same journal (April 25, 1883) as follows:

As a corollary to your French correspondent's remarks in last week's *Medical Press*, I may mention that this phenomenon is not confined to gastric disturbance. It is at times common immediately after sexual connection, and during the act a naturally foul breath may become quite sweet

and of a distinct chloroform odor. The explanation is to me a mystery, but I am *positive* as to the fact.

Puerperal Septicæmia.

Dr. W. N. Bryant concludes a paper on this subject in the *Boston Medical and Surgical Journal*, May 3, 1883, as follows:

I. Puerperal septicæmia is a strictly infectious disease, depending upon the absorption of a specific *materies morbi*.

II. The infecting material may come from without or be developed from within the patient.

III. It is amenable to treatment, which should always have for its first object thorough local disinfection.

IV. It is a preventible disease, and to this end the utmost care should be used by all attendants upon puerperal women to guard them from infection from without, while a systematic course of antiseptic uterine washes should be given night and morning in all lying-in cases for the first ten days following delivery.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—Among new journals one of the most noteworthy is *The American Psychological Journal*, a quarterly, edited by Dr. Joseph Parrish, and published by P. Blakiston, Son & Co. It is well printed on good paper, and makes a neat number of 112 pages. The National Association for the Protection of the Insane and the Prevention of Insanity issue it. Price, \$2.00 a year.

—*The Quarterly Therapeutic Review* is the title of a trade publication issued by Baiss Brothers & Co., Jewry street, London. Price, one shilling.

—In a neat reprint, Dr. Henry O. Marcy, of Boston, discusses the best modern methods of treating operative wounds. The paper was first read before the American Academy of Medicine at its meeting in this city.

—The question of the pathology and morbid anatomy of tubercle is discussed in an article by Dr. N. Senn, of Milwaukee, in a reprint of thirty-four pages. It contains also a good bibliography of the subject.

—In the Department of Sanitary Literature we have received the "Proceedings of the Sanitary Council of the Mississippi Valley, 1883," the "Proceedings of the Illinois State Board of Health, 1883," the "Seventh Report of the Board of State Commissioners of Public Charities of Illinois," and the "Fifth Annual Report of the Connecticut State Board of Health for 1882." The last mentioned is a handsome volume of 400 pages, with maps and a number of special reports on subjects of sanitation.

—A convenient 12mo. "Manuel des Injections Sous-cutanées," by Drs. Bourneville and Bricon, has been published by De la Haye & Co., Paris, pp. 171.

—The ordinance proposed for this city with reference to house draining, etc., has been published by P. Blakiston & Co., 1012 Walnut street, (price, 10c.) and is worthy the consideration of sanitary students.

—The subject of trichinæ and trichinosis is well handled by Dr. W. C. W. Glacier, of the Marine Hospital Service, in a pamphlet of twenty pages, (price, 25c., Illustrated Medical Journal Company, Detroit, Mich.)

—The valedictory address to the graduating class of the Jefferson Medical College was delivered this year by Prof. J. M. Da Costa. It is on "The Higher Professional Life," and is replete with those true and noble views of professional duty and thorough appreciation of the dignity of professional work which have always been well marked in the productions of this admirable writer.

—An interesting study of the various forms of bacteria has been recently made by Dr. T. J. Burrill, of Champaign, Ill. (8vo. paper, 50c., pp. 65). Its contents are as follows: Part I. "Nature and Organization of Bacteria." (1) Existence, (2) Color, shape, size, (3) Movement, (4) Structure, (5) Reproduction and development, (6) Vitality and endurance, (7) Nutrition, (8) Origin, (9) Place in nature. Part II. "Effects of Bacteria." (1) Fermentations and putrefactions, (2) Diseases, (3) Benefits. Part III. "Classification of Bacteria." Sixteen genera (with artificial key) and over one hundred species systematically arranged and described.

—In a reprint describing his last year's work in ovariectomy, Dr. Wm. Goodell, of this city, reports the results of twenty-five cases. Of these six died, but, as Dr. Goodell very correctly observes, this mortality must be balanced by the fact that in not a single instance did he decline to operate. Many ovariectomists do not state in how many cases they decline to operate for fear of ill results.

BOOK NOTICES.

Therapeutic Handbook of the United States Pharmacopœia. By Robt. T. Edes, M. D., etc. New York; Wm. Wood & Co. 8vo., pp. 397.

The plan of this work is to take up the articles in the U. S. Pharmacopœia, *seriatim*, and give their therapeutic action, doses, immediate and re-

mote effects, and in what diseases they are particularly indicated. The sources of the author's information are the Dispensatories and the leading treatises on materia medica. The physiological and toxic actions of drugs come in for a share of attention, and a number of non-official drugs and preparations are discussed in a similar manner at the close of the volume.

The author has performed his task with care, and his collation has been sufficiently thorough not to omit anything of much importance, although he has added but little to what may be found in the last editions of the Dispensatories.

In connection with the publication of this book by the Messrs. Wood & Co., we remark that what appeared to be the unfair and dishonorable action of the Committee of Publication of the U. S. Pharmacopœia in giving its publication to that house has not yet been explained. (See *REPORTER*, January 27, 1883.)

The Diseases of Women. By Heinrich Fritsch, M. D. Translated by Isidor Furst. New York: Wm. Wood & Co., 1883.

The author is Professor at the University of Halle, and writes a condensed practical treatise in a plain and direct manner. The translator has done his part satisfactorily, giving a fair English dress to the author's German. There are a number of wood engravings, but like most of those in Wood's Library of Standard Medical Authors, of which this is one volume, they fall short of what is desirable in point of clearness and careful printing.

A Manual of Auscultation and Percussion: Embracing the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. By Austin Flint, M. D., etc. Third Edition. Philadelphia: H. C. Lea's Son & Co. Cloth, 8vo., pp. 242.

This convenient hand-book has proved very acceptable to the profession, and it unquestionably merits its popularity. Dr. Flint writes clearly, and while he does not go into the tedious and unnecessary minuteness of the German and French Auscultators, he tells all that is of real importance on his subject. The present edition has been carefully revised by him, and has been brought up to the latest advances of diagnostic art. It will no doubt continue to be appreciated by the studious public.

—An illustration of stinginess is cited by an Arkansas editor, who knows a man that talks through his nose in order to save wear and tear on his false teeth.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE DRAINAGE PROBLEM.

Old as the hills, yet ever new, the question of drainage is still in an unsettled and unsatisfactory condition.

It seems that we are altogether on the wrong tack, and that nothing short of a great sanitary revolution can set us straight.

From the mother country we are commencing to hear a great deal about the "pollution of rivers," and it will not be long until the same cry is heard in our own land.

The system of drainage of cities into water courses seems fundamentally wrong, yet it is the plan almost universally resorted to.

Let us take Philadelphia, to illustrate. Most of our drainage, of our rotten, poisonous refuse, flows into the Delaware river. This river is subject to tidal influences; as the tide falls the refuse is carried towards the sea, as it rises it is brought (a goodly portion, at least,) back towards the city; day by day, this foul mass flows down and up, each twenty-four hours, adding greatly to that already in the river.

That this refuse does not pass out to sea, and that it does not subside to the bottom of the river, will be satisfactorily demonstrated to the optic and olfactory nerves of any one who will take the trouble to visit our river front.

Now comes the hot sun of summer; the surface of the water is vaporized under its influence, and some of this poison is carried up with the vapor; when the wind blows from the east, north-east, or south-east, this pestilence-breeding vapor is wafted over our city and into our houses. Do you wonder where epidemics come from? Do you want any further explanation of *so-called* malaria?

As we say, each twenty-four hours adds to this contamination, until, in time, if it is not now, the Delaware river will become one large uncovered sewer.

The famous Delaware river shad are caught at Gloucester, (six miles below Philadelphia); some people eat them and become sick, and wonder why fish make people sick. Is it any wonder? Is it not rather matter for surprise, that we are not all down with blood-poisoning?

The purifying influences of the atmosphere, we fear, are inadequate to render innocuous such enormous masses of refuse as are daily discharged from so large a city.

Our remedy lies in disposing of our waste as nature intended that we should. Horses, cows and dogs do not use water-closets; their refuse is spread sparsely over the soil, which it feeds and enriches.

Organic refuse must go where it belongs, to nourish lower organic life.

We do not mean to deprecate the use of water-closets; they are necessary conveniences to our present state of civilization; but what we mean is that instead of carrying our refuse into water courses, we should cause it to accumulate, in suitable localities, remote from the cities, where it can be utilized in the manufacture of manure.

One of our leading sea-shore resorts is about to introduce such a system of drainage, and they calculate that the sale of the refuse in the shape of manure will pay all the expense of maintaining this system of drainage.

When we have succeeded in educating the public up to the point of realizing the value of preventive medicine, then, and not till then, can we hope that they will understand that money spent for sanitary purposes, is money just as well spent as are the large sums consumed in the erection of unsightly and unnecessary public buildings.

THE INSANE COLONY AT GHEEL.

A correspondent of the *Boston Medical and Surgical Journal* (May 3, 1883), furnishes a very interesting account of a visit to the town of Gheel, which argues much for the advocacy of non-restraint in the treatment of the insane.

Gheel is within an hour's ride of Antwerp, and on one of the direct routes from Berlin.

At the time of his visit there were 1600 insane patients living around as inmates of the families of the colony, and in almost every case they were absolutely free from restraint.

One-half of the sane inhabitants of the town are employed in taking care of their insane fellow creatures, for which they receive pay from the

government sending them or from friends or the patient himself, varying from \$60 per year for paupers, to \$100 to \$1200 for wealthier patients.

The colony is under the charge of a medical director and his assistants, who appoint the families to take care of the insane, this privilege being considered in the light of an honor, for which all strive. The patients are separated according to the degree of their malady: the most quiet and curable are located in the centre of the village; those somewhat troublesome, but offering hope of recovery, are located not far from the centre of the village, and to them is held out, as an inducement for good behaviour, a prospective removal to the more desirable location.

The idiotic children are congregated in a hamlet where special educational advantages are furnished, although they associate freely with other children.

The town is divided into five sections, each of which is presided over by one of the assistant physicians, whose duty it is to make the round of his section once a month, while the director must visit the entire colony twice in the year. Each section is also under the charge of a non-medical "guard," an officer who has the general management, including the enforcement of sanitary regulations. A peculiarly quiet and orderly air pervades the town, which seems to result in part from the natural character of the inhabitants, and in part from a spirit of emulation among them, all wishing to be considered worthy of obtaining and keeping *pensionnaires*. The question naturally arising as to the effect on the normal mind of this constant and familiar association with the insane was answered by the statement that no more insanity exists among the permanent inhabitants of Gheel than among those of other places of its size, and that many families have handed down this occupation through generations without sign of nervous or mental affection appearing among their members.

While apparently doing as they please, the patients are carefully and intelligently watched.

The date at which Gheel began to be devoted to the care of the insane is hard to determine. It

may with certainty be placed as early as the twelfth century, and legend carries it to a much earlier period.

Judging from the account given, this town is well worthy of a visit from all traveling physicians.

THE PARIS MUNICIPAL LABORATORY.

The necessity for similar institutions in our large cities will be apparent when it is realized that during last year out of sixty-two samples of butter examined, only eleven were pure. Preserved vegetables showed the presence of copper in eleven out of thirty-five samples. Milk was found to contain oatmeal, dextrine, white of egg, sugar, brain matter, oils and fat. Wines showed oxide of lead, alum, salt, salicylic acid, and sometimes arsenic in liquids colored with fuchsin. Beer showed picric acid, gall, aloes, colocynth, cocculus indicus, cubeb mixed with nux vomica, and carbonate of sodium, strychnia, box leaves, juniper, etc. Even *residues of fecula manufactories* were found in some adulterations.

This laboratory was erected in 1881, and only costs about \$26,000 per annum, divided as follows:

1 Director of the Laboratory	\$1,200
1 Sub-Director	900
1 Analyst (1st class)	480
3 Analysts (2d class), \$360 each	1,080
16 Inspectors (1st class), \$525 each	8,400
16 Inspectors (2d class), \$360 each	5,760
3 Employés, Porters	1,000
General Expenses	960

Total \$19,780

The rest of the money is applied to the purchase of instruments, books, etc.

Tradesmen, whose places of business are pointed out as those in which adulterated articles are sold, are visited by two officers (inspectors). They request to be allowed to examine the products on sale, and do so, both microscopically and chemically, on the spot, with the means they carry with them. If an article appears to be adulterated, two samples, one for examination at the laboratory, the other to be preserved in case of dispute, are taken, and attested by the signatures of the tradesmen and both officers. Suspected samples

can be lodged at the nearest bureau of police, where they are placed in a special chest for the purpose, and forwarded to the laboratory at the prefecture of police, by means of the prison van. Every article that enters the laboratory is analyzed quantitatively, the result, however, being only made known to the sender on payment of a fee varying according to the nature of the substance, from five to thirty francs. It is upon the figures obtained in this analysis that the chief of the laboratory bases his opinion. Each analysis is registered in a book for the purpose, which remains at the laboratory and forms part of an important collection.

Such laboratories in our large cities would be productive of much good, and would be a wise way in which to spend a portion of the public money.

SOMETHING PRACTICAL ABOUT MICROCOCCI.

"I care not," said a gentleman the other day, who is well known for the practical nature of his contributions to medical science. "I care not whether micrococci are the cause per se, or whether they are the vehicles carrying the cause of zymotic diseases, but I do know one thing—they possess great prognostic value."

He then went on to describe his belief in the following proposition: That in scarlet fever, measles, puerperal fever, and the like, when a microscopic examination of the blood demonstrated the presence of large quantities of granular matter (call them micrococci, or whatever you choose), the prognosis is very bad.

Thus matter, he believes, acts mechanically, it obstructs the capillary circulation, causing the formation of heart-clot, and death from mechanical interference with the circulation.

In support of this view, he cites numerous instances where this granular matter has been found in the blood, when, after death, enormous clots are found in the right ventricle, while the left ventricle is found firmly contracted, dying in systole, failing to overcome the mechanical obstruction offered by this granular matter in the capillaries.

When he finds this condition under the microscope, his prognosis is grave, and *vice versa*.

The discoloration of the skin, found after death in these so-called malignant cases, he considers due to this capillary stasis.

Still further, and what is of greater moment, he is convinced that alcohol possesses great power to alter this morbid condition of the blood. "Make your patients drunk, if you can, but you will find that the tolerance of alcohol in these cases is something wonderful. I used to use carbonate of soda and digitalis, and I lost my patients; I now use whiskey, and I save them." As soon as he has reason to suspect a grave case, from the severity of the symptoms, he commences to use alcohol and pushes it to the stage of intoxication, and he has had most excellent results.

Our authority is so well worthy of confidence that we would be glad to have his recommendations heeded and to have our readers give the alcohol treatment of grave zymotic diseases a fair trial.

It is truly refreshing in these days of ponderous, wordy, theoretical, micrococcal discussions, to have some reliable authority tell us something truly practical about them.

NOTES AND COMMENTS.

An Obscure Affection of the Feet.

When Dr. John McIntyre, Medical Officer of Health for Avoca Circle, S. Natal, Africa, first entered upon his duties, he was extremely puzzled by a curious affection of the feet, which he found peculiar to the Coolies, Europeans and Kaffirs never suffering from it. They complained of excessive tenderness and heat or burning in the plantar surface of the feet. They professed not to be able to walk, and sometimes even to stand. They were generally weakly and debilitated, but how far this might be the result of the inconvenience from the feet he could not tell. The temperature was normal, and, except that they were weak, there was nothing he could find to confirm their statement regarding their feet. Thinking it might be in some relation to specific disease, he tried iodide of potassium; then he tried tonics—quinine, iron, cod-liver oil, arsenic, local embrocations, etc. No treatment seemed to influence the feet in

the least. At last he thought he would try the effect of nerve-stretching. He cut down on the posterior tibial nerve and stretched it. The first few cases were much relieved, but after he had tried this treatment on four or five with apparent benefit, he began to pull the nerve in both directions much more forcibly than in the first cases, and since he began to do so all the cases so treated have been entirely free from the heat and tenderness in the feet, and the general health has also improved. In some of the cases it is over three years since he so treated them, and they have had no return of the tenderness and heat.

His communication appears in the *Lancet*, April 28, 1883.

Six Years' Experience in the Treatment of Syphilis.

Dr. Charles R. Drysdale thus concludes an article on this subject in the *Med. Press*, April 18, 1883:

The treatment of syphilis, commencing with the initial lesion, ought to be continuous, and should consist of very small doses of some mercurial salt, continued for months. When severe symptoms are seen, inunction, calomel vapor baths, or fractional doses of the mercurial salt should be given for a week or so every four hours, in combination with large doses of the iodide of potassium, sodium, or ammonium. Atropia drops should be frequently used in iritis. In gummy deposits the chief curative remedy is iodide of potassium in large doses; but a tonic dose of some form of mercurial salt may be added as a germicide. If cerebral symptoms supervene, they are to be treated energetically with the iodide and with immersion.

Mercury in such small doses seems to do no harm to the general health, and there is much evidence to show that it is a tonic, which may be given even for years with advantage in some cases of anæmia. All cases of syphilis, mild or severe, should be treated by these small doses of mercury in order to prevent the supervention of tertiary symptoms or gummy products. The germ of syphilis has not yet been seen by the microscope, but it exists in all probability, and this is the rational account of the useful action of mercury and iodine, which are both germicides.

Hysterectomy.

Dr. G. Graville Bantock in the *Lancet*, April 14, 1883, says that we should never dream of resorting to oöphorectomy in a case of pediculated fibroid or large multiple fibroids. Experience has already shown it to be useless in these two classes. "But that there are certain cases in which oöphorec-

tomy should take the place of hysterectomy I am free to admit. Such a case is that of a small or very moderately sized intramural fibroid; in such a case oöphorectomy will, I believe, render us good service, and should be preferred because of its small risk. But when the tumor is large, I believe oöphorectomy to be as dangerous as, and in some cases even more dangerous than, hysterectomy has now become under improved methods of performing the operation."

Ear-Ache in Children.

Dr. Samuel Sexton contributes an article on this subject to the *Medical Record*, May 5, 1883, in which he deprecates routine treatment or injections until we have found out the cause of the ache by careful examination, for in a very large number of the earaches in childhood the causes are to be sought elsewhere than in the hearing organ itself, and they will be found to depend, for the most part, on nervous sympathy; the most prominent are dentition, dental caries, and colds in the head. Thus nervous impulses propagated from regions remote from the ear may give rise to pains in the ear—neuralgic otalgia—without perceptible hyperæmia; or the intensity of the congestion arising in a part so richly supplied with blood-vessels may manifest itself as an acute aural catarrh.

To Abort a Sty.

Dr. Louis Fitzpatrick, who has recently returned from Egypt, where all kinds of eye affections are extremely common, writes to the *Lancet*, April 21, 1883, that he has never seen a single instance in which the sty continued to develop after the following treatment had been resorted to: The lids should be held apart by the thumb and index finger of the left hand (or a lid retractor, if such be at hand), while the tincture of iodine is painted over the inflamed papilla with a fine camel's-hair pencil. The lids should not be allowed to come in contact until the part touched is dry. A few such applications in the twenty-four hours are sufficient.

Vertigo.

In the beginning of a communication on this subject by Dr. Edward Woakes, in the *Brit. Med. Jour.*, April 28, 1883, the author says:

The point of view which I propose to submit for consideration in this paper is, that all vertigo is essentially auditory in its seat; that is to say, whenever the symptom of giddiness, disturbance of the equilibrium, defective gait, falling, or

whatever modification of these may characterize the symptom of vertigo, its immediate occurrence is due to a modification of tension of that part of the labyrinthine fluid contained in the semicircular canals, and the appreciation by the ampullar nerve-apparatus of this change of tension.

Erythematous Eruption in Enteric Fever.

Two cases of enteric fever, in which there occurred a scarlatiniform eruption, causes Dr. Whipham to ask in the *Med. Press*, April 18, 1883, whether these are really cases of double poisoning, of mixed scarlet and enteric fevers. The absence of desquamation, and the fact that an erythematous eruption is not uncommon in variola, pyæmia, and other forms of pyrexia, led to the conclusion that there are really instances of enteric fever preceded by erythema and not mixed cases of scarlatina and enteric fever.

Glycerine in Skin Disease.

M. Desguin, of Anvers, has given glycerine internally in certain forms of skin disease with, it is said, marked success, especially in acné punctata and the furuncular diathesis. He commences with four drachms daily and gradually increases the dose. He states that the secretion of the cutaneous glands, which is thick and irritating in these diseases, becomes more liquid, and cutaneous irritation is notably lessened. During convalescence from scarlet fever, he believes that it facilitates desquamation.

A Case for Venesection.

Dr. A. C. Shout reports in the *Brit. Med. Jour.*, April 28, 1883, the case of a young man, who, for some days, had been suffering from a fullness in the head, that rendered his gait unsteady. He fell into a canal, and when seen was lying on his back. His wet clothes removed, body warm, skin dry, breathing slow, face and neck swollen and congested; pupils semi-dilated, and jaws firmly locked; pulse 100, and comatose. Venesection was performed to the extent of thirty ounces, when he slept for two or three hours and awoke perfectly well.

Nephraphy.

Dr. David Newman, of Glasgow, has just performed this operation for the first time in Great Britain. The *Lancet*, April 28, 1883, says of it:

The patient is a female, who suffered from floating kidney, which Dr. Newman determined to treat by fixation. The kidney was reached from behind, its capsule stitched to the edges of the

incision, and several deep button-sutures were passed through the tissues and kidney-substance. The patient has recovered satisfactorily, and is now quite relieved of her former pain.

Spina Bifida.

In the *Brit. Med. Jour.*, April 14, 1883, Mr. Robson, referring to the case related by him in a former issue (see p. 415), and in which he had transplanted periosteum from a rabbit, reported that no new bone had been formed, but he thought the periosteum had helped to thicken the spinal coverings. A new principle in the operation was the treatment of the meninges by bringing together the serous surfaces, after the manner of modern peritoneal surgery.

Chylocele of the Tunica Vaginalis.

Dr. Wm. M. Mastin, of Mobile, reports a case in the *Annals of Anatomy and Surgery* for May, 1883. He considers the morbid condition much less infrequent than either the literature or the numbers of the recorded cases would suggest, and believes that a more careful examination of many so-called cases of hydrocele will substantiate this statement. The treatment he advises is free incision into the sac and ligation of the ruptured and leaking duct.

Carbolized Iodoform.

The following formula is given by C. Sherk (*Berliner Klin. Wochenschrift*) as a great improvement over iodoform:

Rx.—Iodoform,	10 gr.
Acid, carbolic,	5 gr.
Ol. menth. pip.,	2 drops.

The acid is to be rubbed up with the iodoform, and the peppermint oil added subsequently. The disagreeable odor of the drug is completely covered, and it is not again developed even at an elevated temperature.

Belladonna in Gonorrhœa.

Dr. J. Numa Rat states in the *Lancet*, April 7, 1883, that he has treated a few cases of mild gonorrhœa successfully by smearing the penis with ointment of belladonna, and enveloping it in a cloth smeared with the same. No injections were used nor internal medicine employed, and the cure was complete in a week.

The Micrococcus of Cerebro-spinal Meningitis.

Herr Leyden demonstrated this micrococcus before the Berlin Society for "Medicine," on February 19 (*Med. Press*, April 2, 1883). He concludes

that there can no longer be any doubt as to the parasitic nature of cerebro-spinal meningitis. He has found in the exudation liquid of meningitis the same cocci as had been met with in pneumonia, and he has likewise proved the existence of the cocci in a case of pyocephalus.

Aneurism of Both Popliteal Arteries: Cure.

In the *Brit. Med. Jour.*, April 7, 1883, Dr. Samuel Gordon relates the case of a man upon whom, in 1817 (at the age of 29), Mr. Todd tied the left femoral artery for aneurism of the left popliteal, with a perfect cure. In 1820 the same operation was performed on the right side, with a like result. Thirteen years later, the patient died from cancer of the stomach.

Iodine an Antidote for Snake Bite.

Dr. George H. Carpenter, of Moorefield, W. Va., writes to the *Medical News*, April 21, 1883, that he has secured excellent results in two cases of poisoning by the bite of the copperhead, from the internal administration of tinct. iodini comp., fifteen drops in a third of a glass of water, and the local application of the tincture of iodine to the bitten limb or part.

Iodoform in Diabetes.

From the *Gaz. degli Ospitali*, February 4, 1883, we learn that in two cases of diabetes mellitus, Bozzolo has used iodoform (30 grains daily) with good results. In both cases the quantity of urine was decreased; in one (mild) the glycosuria entirely disappeared; in the other (severe), it was lessened.

Popliteal Aneurisms.

From the Sussex County Hospital (*Lancet*, April 7, 1883), is reported one case of popliteal aneurism cured by instrumental compression of the femoral, and one case cured by manipulation and rest.

Albuminuric Retinitis of Pregnancy.

Dr. A. Emrys-Jones calls attention to this condition in the *Brit. Med. Jour.*, April 14, 1883. The prognosis he considers good, so far as vision is concerned, though sometimes patches of choroidal atrophy remain, which considerably diminish the acuteness of vision. For treatment he recommends iron in some form and extra care. He hopes that this note will induce practitioners to take careful notes of the presence of albumen during pregnancy, and the effect on the labor itself, and on the general health of the patient afterwards.

CORRESPONDENCE.

Tænia Medio Canellata in Three Members of a Family.

EDS. MED. AND SURG. REPORTER:—

Last October Mr. R. came to my office, wishing me to relieve his thirteen-year-old daughter of a tape-worm. I advised him to first bring me some of the proglottides as soon as they should be passed. He was able to demonstrate them to me in a short time, and I now prescribed for her as follows: Take to night for supper nothing but oatmeal or barley gruel, and take nothing else whatever before retiring but a cup of absinth tea made of one drachm of the herba absinthii. On rising in the morning take $2\frac{1}{2}$ drachms ext. filicis maris æth. and two minutes after $\frac{1}{2}$ oz. ol. ricini, which passes the extract quickly into the gut. Half an hour later take another cup of the absinth tea the same as the night before.

The next day the father brought the tape-worm, head and all, in a bottle. He stated that it passed without trouble at half-past eight, one hour after the tea was taken, and that the girl was feeling a little weak, but well otherwise.

In January last the mother of the above case came and stated that she also had a tape-worm. I prescribed at once for her the same treatment, but in larger doses. She took a half ounce of the ext. male fern and two drachms of the herb in each cup of tea.

In April, the 14-year-old son came with the same statement. I prescribed for him the same as for his sister.

The effect was in all cases the same, and in the same short time, without any bad consequences, and the above treatment has never failed me in any case.

When Mr. R. brought the last specimen, he thought he would rather not have any more raw beef in his family after this. They had always freely indulged in it, contrary to my advice.

J. H. VOSE, M. D.

Fredonia, Ozaukee Co., Wis., May 7, 1883.

NEWS AND MISCELLANY.

West Virginia State Medical Society.

The Medical Society of West Virginia convened in sixteenth annual session in the court house at Grafton, May 16, the President, Dr. B. W. Allen, of Morgantown, presiding. Prayer was offered by Rev. Robinson, of the Baptist Church.

Dr. W. L. Grant, chairman of the Committee of Arrangements, made an address of welcome on behalf of the committee, and Hon. John W. Mason, on behalf of the Mayor and citizens of the city, welcomed the Society to Grafton in an eloquent and well-timed address, which was received with hearty approbation by the members.

The first Vice President, Dr. Grant, of Grafton, was called to the chair, and the President delivered his address.

Dr. Allen, among other things, advocated the establishment of a full Medical Department in connection with the State University.

Dr. R. W. Hall, of Mannington, from the Com-

mittee on Climatology and Epidemics, presented an interesting report of several epidemics that have occurred in different parts of the State during the past year. This report gave rise to an animated discussion on the subject of typhoid fever, that was opened by Dr. Reeves, and participated in by Drs. Stover, of Richmond, Landis and Baldwin of Ohio, and Gerstell, Jepson, Lazzell and Carpenter, of the Society. The prevailing opinion seemed to be that the disease may arise *de novo*, that it is not contagious in the common acceptance of that term, that many cases recover with but little treatment except the most careful nursing and attention, and that bad symptoms may be often successfully combated with proper medicines. A preamble and resolutions were introduced by Dr. Reeves commending the good done by the Library of the Adjutant General's Office and the Army and Medical Museum at Washington, and calling upon Congress to keep the two united under one control and to secure for them fire-proof buildings, and an annual appropriation that shall be adequate to their support.

Several other unimportant matters were acted upon, when the session closed until half past eight o'clock the next morning.

The committee of arrangements provided splendidly for the entertainment of the members.

In the evening at half past seven o'clock a lecture was delivered by Rev. W. A. Shipman, of the Lutheran church of Grafton; subject, "Materialism."

At nine o'clock a grand ball was given in honor of the Society.

After the lecture the Society was entertained at a ball given in its honor at Brinkman Hall.

The Society reconvened at 8:30, on the 17th, with an increased attendance. Resolutions were offered by Dr. Morgan, of Clarksburg, providing for the establishment of a medical journal to be under the control of the Society, with the aid and co-operation of the State Board of Health.

On motion of Dr. Jepson, the resolution was referred to the Committee on Publication, with instruction to report on the subject at the next annual meeting.

Dr. A. F. Stifel, on behalf of the Committee on the Brock Prize, reported that no paper had been placed in the hands of the Committee.

Dr. J. Frissell read a paper entitled "Health." The paper contained so much information of value to the people, that it was referred to the State Board of Health, to be published in their reports, in order that it might have a much wider circulation than if reported in the transactions.

Dr. J. P. Birney and J. T. Warder were elected to membership.

Dr. Vankirk introduced a resolution which was adopted, commending the work of the National Board of Health, and calling upon Congress for appropriations to enable it to continue its good work.

Dr. Lazell read a paper on new remedies.

A paper by Dr. Myers, on the Germ Theory of Disease was read and referred; also a paper by Dr. Morgan, of Clarksburg, on the Abuse of Ergot in Obstetrics.

Remarks were made on the subject by Drs. Landis, of Ohio; Stover, of Virginia; and Morgan and Gregg.

Dr. Carpenter read a paper entitled *Insanity as a Disease, and the Duty of the Medical Profession of the State in regard to it.*

It was discussed by Drs. Baldwin, of Ohio, Reeves, Kunst, and Howell. The latter offered the following resolution, which was adopted:

Resolved, That a committee be appointed by the President of the Society, whose duty it shall be to collect statistics and general information relative to the management of the insane, and report to this Society at the next annual meeting.

Under this resolution the following committee was appointed: Dr. G. H. Carpenter, chairman; Dr. Fleming Howell, of Clarksburg; Dr. A. H. Kunst, of Weston; Dr. Allen Gettings, of Weston; Dr. G. H. Moffat, of Parkersburg; Dr. A. F. Stifel and Dr. J. B. Reed, of Wheeling.

The following amendment was made to the By-Laws: No member shall occupy more than twenty minutes in reading of a paper before the Society. If the paper prepared is too lengthy to be read within its limit, it may be read by abstract, the paper in form being referred.

The following resolution offered by Dr. Lazzell was adopted:

Resolved, That the Secretary be authorized to purchase twenty-five copies of the Code of Ethics of the American Medical Association for distribution among new members.

Dr. S. L. Jepson read a paper entitled "*Puerperal Fever*," with special reference to its treatment by intra-uterine antiseptic injections. The doctor warmly advocated this as a valuable therapeutic measure to the treatment of this disease, and made reference to cases in which it had been used with great success.

After remarks by Drs. Landis and Morgan, the paper was referred.

The Society adjourned to meet at Clarksburg.

Action of the Medical Society of Harford County, Md.

IN MEMORY OF DR. SILAS B. SILVER, MAY 8, 1883.

Dr. Silas B. Silver died at his residence, "Silverton," in Harford county, Md., on April 1, 1883, of chronic disease of the heart, induced by inflammatory rheumatism. Dr. Silver was born near his late residence on February 20, 1815, and was 68 years of age at the time of his death. He was a pupil of the celebrated Dr. Joseph Parrish, of Philadelphia, and graduated in the medical department of the University of Pennsylvania in 1838. He was quite successful in his early practice, and acquired considerable reputation as a physician; but his health failing, he was compelled to retire from active practice many years ago.

Dr. Silver was ever active in upholding the honor and dignity of the medical profession, and was particularly active in the organization in 1866, and in the subsequent support of the *Medical Society of Harford County, Md.* Although not engaged in the practice of the profession for several years previous to his death, he was, nevertheless, a regular attendant upon the meetings of the society whenever his health permitted, and always expressed sound and conservative views upon the subjects discussed. The *Medical Society of Harford County*, at its recent annual meeting, held in Bel Air on May 8, 1883, unanimously

adopted the following resolutions, which were prepared and offered by Drs. Forwood, Lee, and Hopkins—the committee appointed by the President—as in some degree expressive of the loss sustained by the Society in the death of Dr. Silver:

WHEREAS, The sad visitation of death has invaded our body, and again reminded us of our mortality by the extinguishment of the vital flame of our friend and professional collaborator, DR. SILAS B. SILVER; therefore be it

Resolved, That we, the members of the *Medical Society of Harford County*, in meeting assembled, while submitting to the inevitable—to the laws of nature and to the will of God—do, in sadness and sorrow, sincerely grieve over the loss of an active and useful member of our society, whose efforts were largely instrumental in its organization, as they were also exerted toward the elevation of the standard of medicine, and in the cultivation of the amenities of life between professional brethren.

Resolved, That while experiencing our personal pain in the loss of our fellow and friend, we are still mindful of, and sympathetic with, the sorrow of his immediate family circle; and that we do hereby tender our most profound respect and hearty sympathy to the devoted wife, who so faithfully and so tenderly ministered to every want of the suffering invalid through his long and painful illness; and who now in her widowhood must bear the storms of life without his sheltering arm and love.

Resolved, That a copy of these resolutions, designed to express our esteem and respect for our departed member, be presented to the widow of the deceased; and that copies of the same be offered for publication to the *Philadelphia Medical and Surgical Reporter* and to the *Maryland Medical Journal*, and also to the newspapers of Harford county.

Dr. Forwood, a life-long friend, and one of the attending physicians of Dr. Silver in his last illness, delivered an eulogium upon the life and character of the deceased, and also explained the peculiarities of the patient's disease, and the course of treatment adopted.

Dr. W. W. Hopkins next spoke in terms of high respect of the personal and professional acquirements and standing of the deceased—the friend and cotemporary of his father, the late Dr. Thomas C. Hopkins—of his deep interest in the Medical Society, and of his dignified and unblemished personal character.

Dr. Lee also added a few words in commendation of the services of the deceased—of his professional integrity, and of his valuable services to the Medical Society.

Upon motion, the Society then adjourned to meet in Bel Air on the second Tuesday in November.

W. STUMP FORWOOD, *Secretary*.

Illinois State Medical Society.

The meeting was called to order in Peoria on Tuesday, May 15, at 10 o'clock, by the President, Dr. A. T. Darrah, of Bloomington, Ill.

After prayer by Rev. J. C. Bruce, the chairman of the Committee of Arrangements, Dr. John Murphy, made a brief address of welcome, to

which Dr. Wm. Hill, of Bloomington, responded.

Dr. J. E. Owens read the report on "Surgery."

Dr. Prince, of Jacksonville, showed an apparatus for distension of the bowel.

Dr. J. S. Whitmire showed a new truss for hernia.

Dr. N. Holton read a short paper on dislocation of the left kidney.

Dr. Crummer, of Warren, read a report on a case of deformity from effects of nerve injury.

REPORT OF NOMINATING COMMITTEE.

The committee was organized by electing Dr. N. S. Davis chairman, G. W. Jones secretary.

The following is the report of the committee:

Mr. President and Members of the State Society.

Your Nominating Committee have the honor of presenting the following names of gentlemen as suitable for officers, and recommend their selection for the positions to which they are severally assigned for the ensuing year:

President—Prof. Edmond Andrews, Chicago.

First Vice President—David S. Booth, Sparta.

Second Vice President—Geo. W. Nesbitt, Sycamore.

Treasurer—Walter Hay, Chicago.

Secretary—D. J. Jones, Chicago.

Members of the Judicial Council for three years—Robert Boal, Peoria; Herbert Judd, Galesburg; L. G. Thompson, Lacon.

Committee on Practical Medicine—J. C. Frye, Peoria; J. W. Hensley, Yates City; N. S. Reed, Chandlerville.

Surgery—Roswell Park, Chicago; D. S. Booth, Sparta; J. D. Whitley, Petersburg.

Obstetrics—S. R. Crawford, Monmouth; Ellen A. Ingersoll, Canton; C. DuHadway, Jerseyville.

Gynecology—W. S. Caldwell, Freeport; L. H. Corr, Carlinville; A. F. Rooney, Quincy.

Ophthalmology and Otology—J. P. Johnson, Peoria; Robert Tilley, Chicago; P. H. Garrettsen, Macomb.

SPECIAL COMMITTEES.

J. V. Black, Jacksonville, on Oral Surgery.

Dr. Christian Fenger, Chicago, continued for another year.

W. G. Ransom, Roscoe, continued.

C. Truesdale, Rock Island, on Tetanus.

M. F. Bassett, Quincy, on Vaccination.

J. P. Matthews, Carlinville, on Diseases of Children.

A. Wetmore, Waterloo, on Physiology.

COMMITTEE ON ARRANGEMENTS.

D. W. Graham, Chicago; Chas. Gilman Smith, Chicago; R. C. Hamil, Chicago; H. A. Johnson, Chicago; E. Ingals, Chicago.

Society will meet next year at Chicago.

Items.

—1430 graduates from our various reputable medical schools this spring. What will become of them?

—Injection of a nevus with perchloride of iron produced immediately fatal results in a surgical clinic at Chicago, recently.

—Lycopodium can be put to an excellent use when sprinkled over oiled silk. It prevents the fabric from adhering together.

—A German patent has just been taken out for the manufacture of bottles, etc., from cast iron, containing 12 per cent. of silicon, a compound which is said to resist action of the strongest acids.

—Sounds from the consulting-room.—"How long will it take you to cure me, doctor?" "Well, Mr. Blank, I think you can get back to your desk at the bank about a month, but you will have to remain in treatment for several years." "But you make; I am not Mr. Blank the banker; but Mr. Blank the letter-carrier." "Oh, that alters the case. There is nothing the matter with you but a little biliousness. You will be well in a month!"

OBITUARY NOTICES.

WILLIAM FARR, M. D., C. B., F. R. S., D. C. L.

The father of English vital statistics is dead; he to whom the civilized world owes the present system of statistics upon which all our vital calculations are based, has passed away. He died April 14, aged 75 years.

QUERIES AND RELIEF.

EDS. MED. AND SURG. REP.—Under the "Scott Law," lately passed by the Legislature of this State, no person is able to obtain alcoholic liquors except on the *prescription* of a physician. A patient comes and asks for a *prescription* for some whisky, or brandy, or what not, and says: "I always use it when I become so-and-so," or, "It is the only thing that will do my wife any good when she has a cold," or, plainly, "I like to have a little about the house to use when I need it." Ought I to write him a *prescription* (?) for what he asks for, without further ado? Would it be a *prescription*? Would it be not evading the law, even though I feel assured that he will not use it abusively?

Will you describe the method of obtaining carbonic acid water by means of siphon, referred to by W. B. Atkinson in the *Quarterly Compendium* for January?

I ordered gr. 1-20 doses of belladonna for a child of three years, once a day, at bed time. Each dose caused a brisk and copious purgation within two or three hours of taking. Is that common, or did it depend on idiosyncrasy?

Hilliare, Ohio.

P. F. JEWELL, M. D.

1. Unless the use of alcohol is indicated as a drug by the patient's condition, a physician prescribing it would be evading the intention of the law.

2. You can buy it at any good drug store.

3. The dose is a little too large for a child of that age, though it should not act as you describe, unless under some peculiar idiosyncrasy.

MARRIAGES.

PERRY—THOMAS.—On April 26, 1883, at the First Baptist Church, by Rev. George Dana Boardman, D. D., Dr. Safford G. Perry, of New York city, and Miss Frances S. Thomas, of Philadelphia.

DEATHS.

JONES.—In this city, on the morning of the 3d of May, at his residence, No. 200 Washington avenue, John William Jones, M. D., in the seventy-fourth year of his age.

SHRADY.—Suddenly, April 29, Mary Lewis, wife of Dr. Geo. F. Shradly, of New York.

JENSEN'S CRYSTAL PEPSIN.

Strictly Inodorous and Tasteless, and Perfectly Soluble in Water with

(gr. j. of it will dissolve the boiled whites of two or three eggs.)

THE SEWERAGE SYSTEM OF CAPE MAY.

BY JAMES MECRAY, M. D.,
Of Cape May, N. J.

In your issue of October 14, 1882, you gave a most excellent editorial on Drainage at Seaside Resorts, in which you say, "Fundamentally good drainage at the sea-shore is very difficult to procure, since one of the most essential requisites is a fall or decline in the land so that gravity may aid the water supply in carrying off refuse. At the majority of our seaside resorts the land is very flat. Also it is very essential that the sewer outlets should be so located that they can freely discharge their contents at all times," etc.

The State Board of Health has been making sanitary inquiry and investigation of all the resorts along the coast, and as they are considered the best authority, I will quote from their report, page 132, 1882, on *Sewers*. A careful examination of the sewer system of Cape May was made. Some changes and alterations which were being made gave an excellent opportunity for careful examination. The city has no map of its underground structures, and like most of our cities, much needs a complete sanitary map. The gradients of the different sewers, could not be obtained, *but there was good evidence that they were fairly flushed, and that the fall was sufficient*, unless some special hindrance occurs. One sewer, which was being taken up on account of deficiency of fall, illustrated the fact that portions are sometimes laid with too little fall. There is obstruction because there is irregularity of fall

more frequently than because from *end to end there is too little fall*. In this sewer, the obstruction was found to be caused by a variation in grade which had been made to suit a gas main, and only required the simple remedy of raising the line of pipe before it was reached. The pipes beyond this were so clean as to show a good flushing. The whole system is between three and four miles. As the emptying is into tide water, at points where the tide rises from three to four feet, the outlets are covered a part of the time, *but not so long as to interfere with frequent delivery*. For this reason there should be more frequent man-holes. (Since last visit of Board of Health, April, 1882, every sewer has been well ventilated.) The sewer pipes are from ten to sixteen inches calibre, and often unnecessarily large. They carry all the storm water which enters by gully-traps. At some of these there is free ventilation. It is much easier to keep sewer-gas out of these sewers, than it is to keep it out of the hotels. We find at Cape May the structural provision for water, for disposal of sewage, and all that relates to outside sanitation, either good or capable of easy correction. *There is little danger from sewer-air in Cape May save such as is made in the buildings*, and the city has more to fear from them than they have from the city.

Same report says the soil of Cape May is admirably adapted for a city. It is a common fallacy that sandy soils, as being so loose and porous, are the best adapted for close population. The fact, however, is that gravelly soils are much preferable as percolators. The soil which underlies Cape May city is mostly gravelly, with sand under the gravel bed. The water is soft and pleasant—quite

tasteless, unless a slight sulphur taste is perceptible. We think it can be said that the city has a good and abundant water supply. On the whole, it can be said that few sea-side resorts on such narrow strips of land can be found with so good a water supply. The death-rate of Cape May is only 14.12, showing conclusively that the sewers and water supply are good. There are no resorts on the coast that can show so small a mortality.

The question is often asked, "Is there malaria at the sea-shore?" Any one living here knows full well such a thing cannot exist. Salt water will not generate it. Salt mixed with fresh will. Cape May is so situated that fresh water cannot mix with the salt. The Delaware bay and river are salt as far as New Castle, and in droughts as far as the Lazaretto. So there is no fresh water within fifty miles of the Cape. Malaria is unknown among the residents, as will be shown by the return of deaths. Page 341 gives the principal cause.

Typhoid fever, none; remittent fever, none; scarlet fever, one; diphtheria, none; diarrhœa, three; consumption, one; acute lung disease, one; brain and nervous disease, children, five; heart, two; adult brain, one.

"PEAR GRIT" AS A CAUSE OF ANAL IRRITATION.

BY DR. J. T. ROTHROCK,

Of Philadelphia.

For three successive summers my attention has been called to a case for which I can find no exact parallel in our medical literature, and as it presents some marked features, is, perhaps, worthy to place before the medical public; especially as the diagnosis is easy, the treatment merely abstinence from the offending cause, and because, further, it may give a clue to many other cases with like symptoms.

The patient, a middle-aged, strong, active man, very fond of fruit, each summer was taken with what he first supposed a "fit of piles." There was excessive pain on defecation, tenesmus, flattened feces, and a more or less copious discharge of blood. At one time the pain was so severe and so distinctly localized as to lead to the suspicion of fissure or ulcer of the anus.

The periodical return of these attacks was suggestive, and induced an examination for cause.

Among the fruits quite too freely indulged in by the sufferer were pears. This at once suggested the inquiry as to whether the "grit" that all,

even the best pears, contained, might not have to do with the trouble. On mention being made, it at once brought to mind the fact that on the paper used in the closet there were small white hard bodies, never larger than the head of a pin.

Examination by the microscope revealed the fact that in the feces there were quantities of bodies like those shown in the figure—clearly the so-called sclerenchyma, or stone cells, of vegetable histologists. This furnished the clue to the treatment, which was simply to abstain from the pears, a cure always following.

(Barker.)

"PEAR GRITS" *i. e.*, STONE OR SCLERENCHYMA CELLS FROM THE PEAR. CLUSTERS MAGNIFIED ABOUT 200 DIAMETERS.

An idea of the hardness of these cells may be gained from the statement that they are of exactly the same material and hardness as the shell of the hickory nut.

One may readily understand from this, and from the numerous sharp angles a cluster of these cells show, that lodged in the folds of the mucous membrane at the verge of the anus, even if it were not in an inflamed condition, it would speedily become so, and that to an inflamed or ulcerated membrane it would soon prove an intolerable source of distress.

There is this further consideration in connection with other like cases: may they not be caused by similar substances? Does any one, for example, know whether the sharp-faced crystals of calcium oxalate which are found so abundantly in rhubarb, are dissolved in passing through the alimentary canal? We do know that rhubarb is reckoned among the predisposing, if not actually exciting causes of hæmorrhoids.

The subject is especially commended to the attention of the profession in the country, where observation in this direction will doubtless show that the case above instanced is by no means a solitary one.

I am indebted to my friend and pupil, Thomas Ridgway Barker, for the illustration which accompanies this article.

CONGENITAL ABSENCE OF THE KIDNEY.— TWO CASES.

BY W. A. EDWARDS, M. D.,

Assistant to Prof. Clin. Medical University of Pennsylvania.

During my term as Assistant Pathologist to the Philadelphia Hospital, in the spring of 1882, a foundling was admitted to the house, suffering from marasmus; the babe died in a few days. An autopsy was held, not so much to confirm the diagnosis, as in the routine line of duty. Our work was rewarded by finding the following congenital peculiarity. My notes taken at the *post mortem* table read as follows:

Baby E., foundling, female, age fifteen months, much emaciated, all the thoracic and abdominal viscera normal, but very anæmic. In other words, a verification of the ante-mortem diagnosis.

The kidney of the right side is seen in its normal position, its ureter normal in size; traverses the ordinary course in reaching the bladder. Upon removing the organ its macroscopic appearance is that of a healthy kidney, which *microscopic* examination subsequently proved to be the case.

On the left side the organ and its ureter is nowhere to be found, but in their place the supra-renal capsule is discovered adherent to about the centre of the arch of the diaphragm; it, however, has not the "cocked-hat appearance" ascribed to that gland; it is bound to the diaphragm by firm, well organized connective tissue, which does not appear to have been of inflammatory origin; *microscopic* examination proves it to be the capsule.

No renal artery is given off on this side. Case 2, which is very similar, occurred in private prac-

tice—the child, age twelve months, female, dying because it was a futile effort of nature to vivify the diseased germ, overwhelming constitutional taint attaining the mastery; it was also the left kidney which was absent in this case; the supra-renal capsule was adherent to the diaphragm. *Microscopic* examination made as in the former case, with like result.

In the first case no history was obtainable; the child was found on the hospital steps, so I do not know if it showed any evidence of this congenital defect. The second case was under my observation for some time. The absence of a kidney was never suspected. The urine was apparently normal in amount and color. I never made a critical examination of this secretion, as no symptom seemed to demand it.

These are interesting studies to the embryologist. Why was the kidney in each instance absent and the supra-renal capsule *present*?

Does it not appear as if the defect was not rare? These two cases were met with within the year. Would the kidney in either case have grown in event of the child surviving, so as to present the "horse-shoe kidney," which we not unfrequently see in adults!

While these cases are not excessively rare, I am tempted to record them on account of the popularity and number of nephrectomies that we see reported in the various journals. If either of these children had reached adult age, and the operation of nephrectomy have been performed on them, it is needless to remark that the consequences would have been disastrous alike to patient and surgeon. That this does occur may be seen by consulting the *New York Medical Journal*, Saturday, February 17, 1883, (a case of extirpation of a displaced kidney by Wm. M. Polk, M. D.)

Perusal of this article suggests the advisability of surgeons determining upon some method by which the presence or absence of the organ can be determined beyond peradventure. Upon scanning the various devices adopted by certain surgeons for this purpose, one is struck with the futility of their endeavors to positively settle the question previous to operating.

"OVARIOTOMY."

OPERATION COMMENCED AND DEATH BEFORE COMPLETION.

BY T. H. M'ULLOCH, M. D.,

Of Oil City, Pa.

Mrs. D——, farmer's wife, living four miles

from this city, aged forty-three, mother of three children living; one dead; delivered one year ago by craniotomy, at which time she was kept under the influence of chloroform for nearly one hour, with no bad effects as far as anæsthetic was concerned. But from that time her health failed, and she had been under the treatment of quite a number of physicians.

I saw her first on the 27th of last February. Abdomen distended with fluid, which caused great discomfort, interfering with respiration. Not much emaciated. Pulse, 110; temperature, 100°; bowels regular; appetite good, but, as she remarked, "had no room for food." Cheerful, bright and hopeful.

On examining, per vaginam, found a large tumor, rough, nodulated, immovable, filling up the entire excavation. With great difficulty (and some stretching, as it were, of the index finger), I could outline the os uteri in front of tumor, above the pubes, which appeared to be normal. But I could not pass the sound from its misplaced condition. I expressed to her my inability to give an opinion as to the nature of her disease without first tapping and relieving the distended walls of the abdomen.

On my next visit I drew off nearly three gallons of greenish-colored fluid, which revealed a double ovarian tumor; the one occupying the left side of the abdominal cavity, the other pressed down, occupying and filling up the entire excavation.

I explained to her the character of her trouble; that tapping was only palliative; that an operation for the removal of the tumor was either curative or death; and recommended that an ovariotomist be consulted.

Dr. Varian, of Titusville, saw her with me March 29th, and made arrangements to operate on April 2, at which time and in the presence of nearly all our city physicians, she was placed upon the table prepared for the operation.

It was now nearly four weeks since the evacuation of the fluid, and the abdominal walls were distended nearly, if not altogether, as much as before the tapping. The heart's action was good. She was cheerful, and exhibited an unusual amount of stamina for one under such trying circumstances. When spoken to in regard to the chloroform, she remarked, "It was delightful; that when she took it before she never felt better in her life. She thought she was in heaven;" not thinking, I presume, it would be a reality this time.

The anæsthetic used was $\frac{1}{3}$ chloroform, $\frac{2}{3}$ ether

(Squibb's), using a small towel surrounded with a cone made with a newspaper. After a few inhalations an exploratory incision was made, some six inches in length, in the median line below the navel, exposing the sac. During this procedure she manifested pain by struggling. More of the anæsthetic was added, and the cone placed over the face. Simultaneous with this, by the manipulations of the operator, the sac was opened. The fluid gushed out, emptying the sac rapidly.

Heart ceased to beat; respiration ceased; face livid; pupils dilated. The tongue was seized with forceps; head lowered immediately; nitrite of amyl applied to the nostrils; hypodermic injections of brandy every few minutes; artificial respiration (Sylvester's method) kept up, for forty minutes without any effect. Patient dead.

Post mortem revealed two large multilocular ovarian tumors, with adhesions involving the peritoneum, omentum and mesentery; the womb in a healthy condition, and when dissected out resembled a virgin uterus.

Was death caused in this case by the anæsthetic, or the sudden evacuation of the fluid, or both causes combined?

HOSPITAL COLLEGE OF MEDICINE.

Louisville, Kentucky.

CLINIC OF J. A. LARRABEE, M. D.,

Professor of Materia Medica and Therapeutics and Clinical Lecturer on Diseases of Children.

Hydrocephalus.

Clinical teaching, gentlemen, is intended to fill a place which no amount of reading, perhaps, can occupy. It is the aim and object of such teaching to present to you from time to time the different phases of disease in as typical a manner as possible, so that you may arrange them in the gallery of memory—pictures, as it were, whose impress will come out distinct in future years. I have been enabled to-day by the kindness of my clinical assistant, Dr. Longest, to present several cases illustrating the more important diseases of the brain, of which we have heretofore had occasion to speak. Most of the children here presented have been treated in this clinic before; some of them at periods quite remote from the present.

This little girl, Minnie Williamson, now five years old, was presented and treated here for chronic hydrocephalus in September last. When she was presented to us she had been the subject recently of rapidly recurring convulsions; there was very marked diminution as compared with the size of the head, of the face and facial muscles, with also considerable emaciation of the extremities. She represents to us a particular class or kind of chronic hydrocephalus. I call your attention to the shape of her head in the first place, although it is now so changed since the time she

was treated as to be scarcely recognizable as the same. The circumference then was twenty-one or twenty-two inches. It still retains the form and shape, however, of the hydrocephalic head. The face as compared with the head is seen to be still diminutive, although if I hide from your view that portion of the face above the eyes, the countenance may be still considered well up to one of her years. This change in appearance you observe occurs then not because the face is smaller, but because the head is larger than it should be. This child represents the hydrocephalic head perhaps better than any picture here. The countenance converges to a point at the chin, and has its greatest divergence at the parietal prominences. Let us then say something concerning these cases in general.

Chronic Hydrocephalus is recognized under that name, and distinguished from another form called acute hydrocephalus. This condition is one which we may divide into two kinds or varieties, as regards mechanical symptoms, viz., external and internal. First, as regards the external, we mean as the term implies, that the water is upon the brain—external to it—instead of within it. In the external variety we have the water which produces the deformity, the separation of the bones and the distortion of the features between the membranes of the brain and the brain itself; between the dura mater and the arachnoid, or in the sub-arachnoid space. This effusion is the result probably of inflammatory action, because it is the province of serous membranes when inflamed to produce serous products, and these envelopes when the subject of inflammatory action pour out an amount of fluid differing perhaps in character, but not essentially, from such fluids elsewhere. The point to be observed is this, that the brain substance with its convolutions and divisions is pressed down into the base of the skull by the supernatant water, so that in this case the water occupies the upper portion of the head. In hydrocephalus internus the water is within the brain and the ventricles, which are intended in the normal condition of things, to contain a certain amount of secretion, by the augmentation of which the brain is opened up in the form of the leaves of a book, the brain convolutions being pressed apart, the water occupying the lower part of the cavity of the skull. This classification is important, and the discrimination of these conditions is accomplished not so much from the shape and contour of the head as from the expression of the eyes.

This child to which I now call your attention is a case in which the hydrocephalus is internal. The orbital plates are normally placed in a nearly horizontal position. In the internal variety of hydrocephalus the fluid presses these down, causing them to assume sometimes an almost perpendicular position. This change in the position of the orbital plates results in a like change in the axis of the eye, and consequently in its expression. The expression is downward, the eye bulged from the socket, and the sclerotic exposed. This is a merely mechanical effect of the water. This child has not the power to control the movements of the eyes. A distinction of this character is, however, of no importance in the treatment of the disease.

Here is another case in the person of Wm. Terry, æt. 5 years. He was treated two years ago at this clinic for chronic hydrocephalus. His head, while then measuring perhaps not quite so much as in the instance of the little girl sitting over there, was nevertheless so large and heavy that he could not support it upon his neck. You see him now so far restored that he is a bright—very bright—and intelligent little fellow. He is able to walk alone, in fact, he goes anywhere he chooses, just as other children of his age, and he has not had a spasm for a year. Here, then, we have two cases of external hydrocephalus, and one of internal, to illustrate the remarks I have to make on this extremely interesting subject—interesting because it concerns in its causes a variety of histories.

The etiology of chronic hydrocephalus concerns the past as well as the present. We may name the causes perhaps on three fingers. As we have often before, we will have here to allude again to the fact that in the study of the diseases of children we are gleaners in the field of practice. We observe the results of these little points which are omitted perhaps in the practice of adults, and as we follow those who practice upon adults, we are perhaps better able to judge of their success in the treatment of the various diseases.

Here again too we may well say we are treading upon the ashes of ruined constitutions, these ashes again disseminated to future generations; for the causes are in the first place tuberculosis, in the second syphilitic diseases, and my own limited experience teaches me to place before either of these intemperance, away back perhaps, on the part of the parents, as having to do largely with the production of this and kindred disorders. These I mention as the principal causes, and some of them begin to operate before the birth of the child, because the accoucheur notes that it is not unfrequently the case that he has to resort to various means to accomplish the birth of children whose heads are enlarged, and who are the subjects of this disease in utero. The causes of the disease then having spent their activity, and the effect remaining, these cases are generally unpromising. If we succeed in enabling them to bridge the difficulties incident to infancy, they usually succumb to those of childhood which come along afterwards, as the eruptive and epidemic diseases. Weakly by birth, and sickly by inheritance, when they meet the pitfalls that beset the path of childhood, they readily succumb, seldom reaching the period of adult life. It is perhaps fortunate, because, unable to care for themselves, they become an incubus upon their families and perhaps upon others.

Tubercle, in my estimation, should rank very high as an element in its production; whether or not there are present inflammatory processes of a low grade, we are not able to say definitely. I incline to the belief that, at least in the internal variety, such an inflammation of the lining membrane of the ventricles is present, a condition similar in many respects to basilar meningitis.

We have foreshadowed the times at which these diseases may occur. They generally show the first symptoms by a change in the expression, and by the early occurrence of convulsions. Convulsions do not originate the disease, however,

and it must make considerable progress before convulsions occur. These convulsions mark the progress of the disease, the pressure then taking place, and the absence of convulsions mark that period which is characterized by its quiescence. Mark, for instance, the periods of repose in tubercular deposit of the mesenteric glands. With the development of the convulsions you have the gradual emaciation, the wasting and atrophy of tissue, a want of assimilation; the limbs are small, dentition is delayed, and the head makes its impress upon the pillow with a wet spot—a mark always of debility. About this time another symptom of importance appears: the child frequently puts its hands to its head for hours at a time, and sometimes presses its fingers into its eyes; certainly a singular performance for a little child. All the symptoms which go to make up a disease in childhood differ from those attendant upon the same disease in adult life. Pain as felt by the adult is one thing; in the child, very different in its manifestations. As a general thing, you may make this distinction—the child, when the subject of continued pain is the subject of organic disease; this may or may not be true in adult life. So that if a child manifests the evidences of pain for days together by pounding the head with the hand, bowing down upon the floor, bumping the head against a door, etc., you may be certain a structural disease is present.

In hydrocephalus, the muscles of the neck become extremely weak and emaciated. This is a fact of importance when you come to make the distinction between meningeal inflammation, giving rise to pain in the head, and hydrocephalic symptoms. When meningitis gives rise to pain in the head, the head is fixed. In hydrocephalus the head rolls in any direction. I take it, however, that the principal point which would make your distinction in the diagnosis is the gradually increasing distension of the fontanelles, which, as you know, should be completely closed at the second year.

The case I show you now is illustrative of the syphilitic variety of the disease. I have already investigated the case far enough to learn that the history is one of that diathesis. The child is perfectly blind from syphilitic keratitis; it has been the subject of eruption since birth, and these effects of the operating cause have preceded the development of the hydrocephalus proper.

In the treatment of these cases, we have endeavored to represent, as far as possible, the different causes.

In the first case presented here there are unmistakable evidences of the strumous diathesis; the child has had extensive abscess in the hip joint, which was evacuated at the time by the aspirator, resulting in a cure without leaving any deformity worth mentioning, except shortening of the limb. In the treatment of such cases, as in the treatment of all others of malnutrition, recourse must be had to reconstructive agents. It has been proposed by some to tap the head and evacuate the fluid, afterwards resorting to strapping to prevent its refilling. I question the propriety of such a proceeding; not through the fear of immediate death, but from the improbability of such treatment relieving or preventing a second effusion.

Those who have watched closely the clinical history of the effusions of pleurisy will, I think, bear me out in the remark that they are seldom thus cured.

In this second case, the treatment was by mercurial inunction. This treatment was followed out for some time, and under it the child began to improve; not at first with regard to the observable symptoms, but with regard to the nutrition; and by continuing the treatment all this improvement has been brought about. The first case was treated by reconstructives entirely, the iodides and malt. I believe we have in malt properly made one of the best reconstructives known. This child has taken a great deal of it. It does good in all those cases in which malnutrition stands in the relation of cause to effect. This blind skeleton of a child has undergone no treatment whatever, though it has been under my continued observation for some time. It has been the subject of large sloughing sores. At that time it was treated with some mercurial inunction, but it was thought the child would soon die, so nothing further was done. At one time it had such an odor about it as to be almost unbearable, necessitating the use of chlorine and Labarraque's solution.

Let us now consider some of the other diseases of the brain closely related to this. In the first place I wish to fix upon your minds the signification of certain terms used, and confused in the minds of students. Of course we may have inflammation of any part. Different membranes surround the brain and spinal cord, and differentiation has been made in regard to diseases of the brain on the basis of the technicalities used to designate the parts, as you might coin for instance such a term as "piaitis." Such distinctions, however, if they might be discriminated during the life of the patient, I am not prepared to say would be of any particular benefit in the treatment of the disease; yet it is important that the diseases affecting these membranes should be differentiated from those producing hydrocephalus. Between acute and chronic hydrocephalus there is this distinction: An active inflammation of the brain coverings was formerly designated acute hydrocephalus; the term is now abandoned, and this inflammation designated as simple meningitis. The result of an inflammation of these membranes of any character is an effusion of serum upon or between the membranes of the brain. There is a form of acute inflammation also which we call tubercular meningitis, and of these forms of acute inflammation the tubercular is present in more cases than the simple, and meningitis in some variety is extremely common in children. Dr. West in his admirable work on Diseases of Children, I think says $\frac{9}{10}$ and a fraction % of all diseases from which they suffer consist of some form of meningitis.

In simple meningitis a different set of causes operate to produce the disease. Suppressed eruptions, whether they be of the so-called eruptive diseases or manifestations upon the skin of various kinds, and perhaps more frequently than all the injudicious treatment and suppression of discharges from the ear by pledgets of cotton introduced, whereby structural disease of the bones takes place. More cases in practice come under

the observation of the physician of meningitis caused by the suppression of discharges from the ear, or perhaps from treatment of diseases of the ear or by delayed treatment of such diseases, than from all other combined causes. It may be a result of that process we so familiarly know as "taking cold;" it may be the result of the circulation of disease-poisons in the blood. This form occurs in the inception of such diseases as small-pox, scarlet fever, and rheumatism. It may be the result of various constitutional peculiarities, as where there is a tendency to diseases of the nervous system, as for instance from the complications from typhoid fever, etc. Again, it may be the result of so simple a disease as that we call whooping cough, a disease never fatal of itself, but sometimes so because of the complications which it causes.

I saw a case this morning which looked like a commencing case of pneumonia. The child had had the whooping cough for four or five weeks; it now suffered from a sudden rise of temperature, suppression of the cough, spasmodic blushes over the skin, and labored and restrained respiration. I was about to pronounce it incipient pneumonia, but more patient examination led me to believe it was suffering from congestion of the brain, the effect of whooping cough, and I so treated it, and will in all probability so relieve it. A mistake in the diagnosis, under such circumstances, followed by the course of medication such diagnosis would indicate, is almost necessarily fatal.

The symptoms which usher in an attack of simple meningitis are usually plainly marked, and essentially different from those which precede the development of chronic hydrocephalus. I have lately been able to prevent the development in a child of meningeal inflammation by an early recognition of the initial symptoms by appropriate treatment. The symptoms attendant upon the initiatory stage are usually a change in the child's disposition. Moroseness and fretfulness, perhaps, attracts the attention of parents, but seldom excites alarm. In the case to which I allude, the child, from an amiable, happy, cheerful creature, was changed into a morose, fretful and peevish child, almost constantly filled with fear. I found she had not slept for several nights; that there was intolerance of light and contraction of the pupils; there had been vomiting. There had been no crying with all her madness. The cry in simple meningitis is not attended by the increased secretion of tears which usually occurs in grief. As long as tears flow freely during a cry, there need be little apprehension of serious brain trouble. With these symptoms we have a particular kind of vomiting—vomiting not preceded nor attended by nausea, vomiting by central irritation. After this, the appetite is good, and the child sometimes eats voraciously. This symptom, combined with constipation, puts you on your guard. Cases often arise in which it is difficult to distinguish the disease from remittent fever. While it all seems plain to talk about, yet when you come to the bedside of the individual you will oftentimes find yourself puzzled. You may find the child presenting all the symptoms here mentioned, save that in stead of constipation the child has diarrhoea; that one thing throws you off adrift. I would teach you, therefore, to depend upon the

grouping of symptoms, letting pathognomonic symptoms pass.

A word, now, upon the tubercular variety. In this form there are found after death depositions of tuberculous matter scattered like millet seed along the course of the vessels. Here, as in tuberculation of the lung, a prodromal stage, which may or may not have been noticed by the friends, exists. This form is more common than the other variety, and infinitely more fatal. Indeed, I would certainly be very skeptical as to the correctness of the diagnosis when recovery is said to occur from this form. Among the initial symptoms will occur weariness, lassitude, hectic fever, giddiness, vomiting, and constipation of the bowels—there may be diarrhoea, as sometimes occurs in infiltration of the mesenteric glands. A case of this kind closely resembles typhoid fever. I have seen cases of this description treated for four or five days under that diagnosis. I call to mind a case that occurred under my notice a few weeks ago. At that time the mother was not even alarmed. I predicted then the result which has since been fulfilled by the death of the child.

Tubercular meningitis is followed by paralysis of motion of one arm or leg; when this stage in the case is reached, I advise you to say that the child will inevitably be lost, and never change this prognosis because of any sudden change in the appearance. I could not tell how often I have been called to the bedside of these little patients to hear the statement that the child is better, and to be besought to continue my efforts to save it. Do not allow yourselves to be deceived by such ignes fatui as these. It is the mere flicker of the candle before it goes completely out. Nothing is more common in brain troubles of this description than to have this lighting up of the symptoms.

Here, now, is a boy who has been the subject of circumscribed simple inflammation at the base of the brain. His condition was diagnosed at the first visit to be such, and the parents then informed that it might concern in its effects some of the nerves which find their origin here. One of the products of simple inflammation is lymph, or semi-organized material evenly spread over the surface of the membranes. In the tubercular variety, post-mortem reveals only the tubercles studded along the courses of the vessels, and fluid; but in this case we are concerned in the character of the product deposited. Here, after an unpromising period of weeks, the boy emerged from a comatose condition to display the symptoms of a chronic form of inflammation. Long before this state, however, hearing was completely lost. This is the result of the involvement in the process of the auditory nerve at its origin. Otherwise, this boy's intellection and perception is good. It is possible that under the administration of such agents as iodide of potassium, he may recover this lost sense. I have had such a case to recover spontaneously in the person of a child at Danville, even after the lapse of a sufficient period to permit of a considerable degree of education in a deaf and dumb institution.

I have now another case illustrative of an entirely different class of brain affections. This case I show also on account of its novelty. It is scarcely probable unless you practice in mountainous districts that you will see another like it.

This is a case of cretinism. By cretinism is distinguished a class of individuals who, although in the animal scale they are perfectly developed with the exception of the power of locomotion and in height, have brains that are dwarfed and stunted to such an extent as to render them hopeless and helpless imbeciles. The condition here presented, however, is very different from idiocy. We have with us various grades of brain development, and those who practice among children will soon remark the different grades of development and intelligence displayed in childhood. Idiots are quite common; cretins are not common in this country. Our knowledge of the cause of this condition is very limited; however, it has come to be associated with certain climates: aside from this, various causes are able to impress the growing brain to arrest or prevent entirely its development; it may receive an impress which forever stamps it with imbecility. The disease, as I have said before, occurs in mountainous districts. Altitude rather than latitude has to do with its production, and a singular fact about it is that it always occurs in connection with another disease of altitude, viz., goitre. Goitre is essential to cretinism. The mother of this child I here show you has the goitre well developed. The child you observe has a well-shaped head and a good countenance; there is no idiotic stare there. Another peculiarity about these children, noticed in the countries where they most frequently appear is that they are wonderfully free from the diseases incident to childhood—measles, scarlet fever, whooping cough, etc., etc., they escape them all; why we do not know, but there is this it appears to me hinted in the fact, viz., the necessity of the integrity of the nervous system as a factor in the production of disease. The ignorant Alpine has a consolation, however, which this mother under more intelligent surroundings can hardly feel. Among them they are called God-children. They believe these children are perfectly formed in every respect of body, but that when they descend to the earth, through the power of the Almighty, their souls are kept in heaven, and that when they die their bodies go to make the perfect being by union with their souls in heaven.

As to the exact pathology of the disease we know nothing. We have then simply to show you the case and leave it as we find it, a case of cretinism.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, April 5, 1883.

The President, R. A. Cleemann, M. D., in the chair.

Dr. W. Goodell exhibited some

Calcareous Particles Passed per Vaginam.

The previous history had been that of menorrhagia, and multiple fibroids were found in the womb. One of these fibroids had evidently taken on calcareous degeneration, and had subsequently broken down and discharged these fragments into the uterine cavity. He stated that these parti-

cles were not true bone, but merely the product of a disorderly deposit of lime, which possessed none of the osseous elements, not even cartilage corpuscles. This calcareous degeneration tends to cure the disease by breaking off the vascular filaments of attachment and lessening the nutrition of the fibroid. In one instance, the specimen of which is now in the Museum of the University of Pennsylvania, he had seen three fibroids wholly converted into stone. These stones were, however, very light, and not like those of the bladder. It was the expulsion, *per vaginam*, of these uterine calculi, which had greatly puzzled the older anatomists.

Dr. Goodell also exhibited two calculi, and related the following histories of two cases of

Stone in the Female Bladder Associated with Fistulous Connection with the Bowels.

The first case was that of a patient of Dr. C. A. McCall, who sent her to him in October, 1881. For the preceding four years she had suffered very much from vesical tenesmus. She frequently broke wind *per urethram*, and often passed through the same channel the seeds of raspberries, of tomatoes, and of pears. A year before Dr. Goodell saw her she had voided a great deal of her urine per rectum for several weeks. Dr. Goodell detected two stones in the bladder, and removed them. At once all the fistulous connection between the bladder and the bowels disappeared, and the patient got well. This rapid recovery led him to think that there had not existed any fecal fistula, but that the vesical tenesmus was so great as to cause a rectal tenesmus, which was masked by the former, and that the seeds and wind were voided per rectum unconsciously by the woman when attempting to empty the bladder. But he had been led to change his views by the following case, which he had seen with Dr. Wm. Corson, and which Dr. Ellwood Corson was kind enough to report for him.

Misled by the first case, Dr. Goodell was not at first disposed to admit the existence of a fecal fistula, but from the subsequent history of the case there can be no doubt of it. In this case he believed that a pelvic abscess had burst into the bladder, and also into the rectum or small intestines, which had established the communication between the two viscera. Like the first case, as soon as the calculus was removed the fistulous tract closed, and the patient got well.

Mrs. R—, American, aged fifty years, the mother of five children. For three or four years prior to November, 1881, she was troubled occasionally by the passage of small calculi; but her health was reasonably good, with the exception of backache and an almost constant pain in the right iliac region. She often expressed her belief that there was something growing in the right side. There was no tumefaction in that region, and her opinion was based on the pain and distress she felt. She never applied to her physician for relief of this suffering. She was also troubled with constipation.

In November, 1881, she made a visit to the country and took a long walk. On her return home she had a constant desire to urinate, and she then noticed, for the first time, that her urine had an unnatural color and a very unpleasant

odor. The quantity passed was not excessive. This condition continued for five or six days, when there occurred a sudden gush from the bladder of a very offensive mixture of pus and urine, accompanied by great pain and straining. Her pain and distress became so great and was so augmented by being on her feet, that she was compelled to remain in bed. After the free discharge occurred, the pain in the right iliac region ceased, and she has never had any return of it. As she was troubled with constipation she was directed to eat stewed prunes, and she soon noticed that that the prune skins came from the bladder, as did other articles of food, along with the urine. Every day she was troubled with the escape of gas through the urethra, and this gave her as much pain as the passage of solid matter. She says that she occasionally passed urine through the rectum. She became greatly emaciated, and was but partially relieved of her suffering by the constant use of morphia.

Until January 20, 1882, she was under the care of homœopathic physicians. On that date Dr. Wm. Corson was called to the case.

February 10th, Dr. Wm. Goodell saw her and diagnosed stone in the bladder.

February 20th, she was etherized and the urethra dilated, and a digital examination proved the existence of a calculus, about $\frac{3}{4}$ of an inch in diameter, attached to the fundus of the bladder. This was removed by Dr. Ellwood Corson. In attempting to dislodge the calculus, it crumbled on slight pressure with the extracting forceps, and proved to be a mass of fecal matter with a calcareous crust, but slightly thicker than an egg-shell. While she was under the influence of the anæsthetic, an attempt was made to wash out the bladder, but after injecting $\text{f}\overline{3}$ xij of water, and finding that it escaped into the interior of the body and did not remain in the bladder, the washing-out process was discontinued. After she regained partial consciousness and made a strong straining effort, the injection came away through the urethra. As there were some doubts expressed as to the possibility of there being an opening from the bowels to the bladder, she was induced to eat a few stewed figs and the seeds were seen to come from the urethra; on another occasion $\text{f}\overline{3}$ viij of carmine-colored water was injected into the rectum and was immediately drawn from the bladder by means of a catheter. After the removal of the calculus it was thought proper to keep the bladder washed out daily with warm injections, and to regulate the bowels with mild aperients; but after persisting in this course of treatment for four days it was abandoned, as it caused her great discomfort and did not improve her condition. Afterward she was allowed to eat such food as the system craved, care being taken to select such articles as would not leave an irritating residuum. She rapidly improved, and since April, 1882, has had no trouble with her bladder. If she eats acid fruits or drinks lemonade she has some irritation in passing urine. That there was a fistulous opening from the bladder to the rectum, there can be no doubt; and when we take into consideration the fact of an abscess forming somewhere in the right iliac region and opening into the bladder, and that the food passed from the bladder in a semi-digested state, and the absence

of a fecal odor, there is a strong probability that there was also an opening from the small intestines into the bladder.

Dr. J. C. Morris has seen two cases of pelvic abscess bursting into the bladder. One case was in the person of a night nurse at the Episcopal Hospital. A tumor in the lower part of the abdomen first attracted attention. The uterus was drawn up out of reach of the finger when making a vaginal examination; an inflammatory mass could be felt between the uterus and bladder; every half hour a mixture of urine and pus was voided *per urethram*. If a catheter was passed into the bladder and turned to the right, urine escaped through it; but if it was passed to the left, nearly pure pus passed through it. Examination with the sound showed a large fibroid in the anterior wall of the uterus. This tumor having undergone purulent degeneration, and a fistulous opening being established into the bladder, the pus escaped through the bladder. A galvanic stem pessary five and a half inches long was introduced into the uterus, and was finally successful in effecting its reduction to the normal size. This woman died of fibroid phthisis, and at the *post-mortem* examination the uterus was found but slightly enlarged and the fistula into the bladder was not seen, but a communication from the small intestine into the bladder was discovered.

Dr. Wm. H. Parish has seen one case of fistulous communication between the bladder, vagina and small intestines, resulting from an attempted abortion, and consequent cellulitis. After long-continued pelvic symptoms, food commenced to pass through the bladder and the anterior and upper portion of the vagina. Water injected into the vagina passed into the bladder, but a sound could not be made to follow it. The food which passed through the fistulæ was incompletely digested.

Dr. Elliott Richardson read a
Report on Results of Post-mortem Examination of the Body of Lina Earl.

This woman was operated upon September 22, 1880, for removal of a living child from the uterus by Cesarian section, as modified by Porro and Müller. A report of the case was published, *Amer. Jour. of Med. Science*, January, 1881. The immediate results of the operation were in every way favorable. The child was living, and the mother made a speedy recovery.

She died in New York city on February 24, 1883, two years and five months after the operation. She had been for two years previous to her death at times an invalid, and was under my care occasionally for the treatment of attacks of acute rheumatism, anemia, etc., to which her life of hardships and exposure as an exhibiting curiosity rendered her peculiarly liable. The more recent symptoms which appeared during the last illness I did not witness, but learned were attributable to defective action of the kidneys.

At the post-mortem examination, made about 9 p. m. on February 24th, ten hours after death, there were present Drs. Satterthwaite and Hegeman of New York, and myself.

Inspection of the body showed the long bones of the extremities to be deformed as in rachitis; deformities which had not been so apparent during life. General anasarca was present. On the

surface of the abdomen a cicatrix was observed extending from a point about $1\frac{1}{2}$ inches above the umbilicus to within about $\frac{3}{4}$ inch of the symphysis pubis. This cicatrix was the remains of the abdominal incision made at the time of the operation for her delivery, and occupied the linea alba directly in the median line, except that at the umbilicus it was deflected to the left. Nearly the whole of that portion of the cicatrix extending between the symphysis pubis and the umbilicus was the site of a large hernia, which, however, did not extend into the latter. This hernia I had seen during the patient's life. It began to appear about six months after the operation, and received no treatment whatever until by its size it became inconvenient; then a bandage or truss was applied, and this she wore constantly until her death. The production and enlargement of the hernia had been greatly favored by the woman's course of life as an exhibitor of herself and child, for the latter she lifted up and held in her arms many times a day, in order to display it to her visitors, even after it had become much too heavy for her to carry.

The body was opened by a long incision from the top of the sternum to the symphysis pubis. This incision was deflected to one side opposite the cicatrix of the old abdominal wound, in order that the relations of this to the abdominal contents might be more closely observed. The body, as before stated, was anasarcaous throughout; some clear serous fluid was found in the peritoneal cavity, and a good deal in the cavities of the pleural and pericardial sac. I very much regret that I have no data of microscopic appearance of any internal organ or tissue to give. Only the gross lesions which could be detected by the unaided eye in a hasty examination can be given. The heart was not opened, but the left ventricle appeared abnormally large. The lungs were oedematous, and pneumonia of the right side was observed. The spleen was enlarged. The liver presented an appearance of fibrous or "hob-nail" degeneration. The kidneys showed unmistakably the existence of Bright's disease. The abdominal and pelvic cavities gave no evidence of any peritoneal or cellular disease. The hernia was found to be covered by peritoneum and skin; the remaining structures having parted to admit the protrusion of the intestines and peritoneal covering. No adhesions between the cicatrix and subjacent structures could be detected, except at the lower angle of the wound. It was at this point that the stump of the uterus had been fixed in a manner similar to the disposal of the pedicle in ovariectomy. A fibrous band was found extending from a depression in the abdominal wall at this point, to a body consisting of the remains of the uterus.

Dr. Satterthwaite, who examined these specimens, writes me that this body, which occupied nearly the normal position of the cervix uteri, except that it was displaced somewhat anteriorly, presented the following characteristics: "The extreme length of the stump was 4.75 cms. (1.87 inches); vertical thickness, 2.5 cms. (1 inch); its breadth, 1.5 cms. ($\frac{1}{2}$ inch). On attempting to pass a uterine probe into the os externum, it was found to enter with difficulty, though the cervical canal was capable of admitting a No. 10 (English)

sound. The mucous membrane was coated with a deposit of white, thick, gelatinous material, and was intact for a distance of 3.5 cms. ($1\frac{1}{4}$ inches). No naked-eye evidences of cicatricial tissue were made out at the amputated extremity of the neck."

Examination of the pelvis *in situ* was of much interest to me. Measurement of the superior strait gave for the

Conjugate diameter, 2 inches exactly.

Transverse diameter, $4\frac{1}{4}$ inches.

Oblique diameter, $4\frac{3}{8}$ inches.

The pelvis was a rachitic one, although the pavilion did not present the wide-spreading alæ or the diverging anterior-superior spinous processes of the ilia, which are the usual deformities of rachitis in this part of the pelvis. The true pelvis, however, presented highly characteristic deformities. The sacrum was at its upper part dislocated, and pressed downward and forward into the pelvic cavity, while the lower extremity being held by ligamentous bands to the ischiæ and pubic bones, caused a sharp bending forward of the last three vertebræ of the sacrum. This deformity implied abnormal softness and pliability of the bone at a time when the individual was of sufficient age to either stand or sit erect, so that it alone is conclusive evidence of rachitis having existed. The normal curvature of the pubic bones was nearly lost, so that they receded from the symphysis in nearly straight lines backward and outward to join the ischiæ and ilia; the two pubic bones, when viewed from above, forming an abnormal angle at the symphysis. The shape of the superior strait was therefore obtusely cordate, deeply indented at its base by the promontory of the sacrum projecting far into it. I was much surprised at the evidences of rachitis, which became more and more conclusive as the examination proceeded, since the history of the patient formerly given me was that of excellent health from birth to the time of the operation in 1880, and we were told by the woman and those who had known her best in early life, that she was in figure almost an exact counterpart of her father. These facts, as I supposed them to be, led me to believe that her shape was due to arrested growth, and not to rachitis. It will be interesting to know that the child of this woman is now living, that he is well developed, and presents no deformity nor any symptom of rachitis. He is of fair size for his age.

In closing, I would draw the following conclusions from the examination:

1. That the deformity of pelvis and extremities was due to rachitis.

2. That the operation had nothing to do with the patient's death.

3. That the operation caused the patient no inconvenience except from the hernia which would either not have become developed, or at most would have been small, had it not been for the exposure of the woman to unusual strain, and her total neglect to resort to any treatment until the hernia became large.

4. That success in so far as the woman was concerned would have been possible, and even probable, with diameters so large, if embryotomy had been resorted to in this case; but the operation would still have been dangerous, and the child would necessarily have perished.

Dr. R. P. Harris remarked that of five Porro operations in this country, four have proved fatal.

This is the first successful operation in which a *post mortem* examination has been obtained after entire recovery.

In reply to Dr. A. H. Smith, Dr. Richardson stated that no trace of a fistulous opening between the stump of the uterus and the abdominal wall existed at the time of death.

Dr. B. F. Baer read the history of a case of
Suppurating Cyst of the Broad Ligament, which had Perforated the Bladder,

and exhibited the specimens removed by laparotomy. (The case will be published entire in the *Amer. Journal of Obstetrics*.) The characteristic points were chills, exhaustion, anorexia, tenderness throughout the lower abdomen, and a small painful tumor in the left iliac region, with great irritability of the bladder. Pulse 120, temperature 100° to 102°. The tumor extended down between the bladder and the uterus, and the latter was retroverted. Douglass' cul-de-sac was occupied by a thin-walled fluctuating cyst about the size of a large orange. The uterus could be moved slightly from side to side. The anterior tumor rested on the bladder and was adherent to it. The history showed a slowly growing cyst with purulent contents, commencing about three years before, when the first chills and a mild septicemic fever had occurred. Gradual emaciation had been progressive since that time. Tympanitic resonance of the tumor gave evidence of decomposition, with evolution of gas. When the catheter was passed before operating, several ounces

of very fetid pus flowed through it, showing a spontaneous rupture of the cyst into the bladder. The cyst was found adherent to the abdominal wall and to the bladder, but not to the intestines nor uterus. The cyst was aspirated and removed by laparotomy. The pedicle, consisting of broad ligament and fallopian tube, to which the left ovary was adherent, was transfixed and ligated. The cyst in Douglass' pouch arose from the opposite broad ligament; it had formed no adhesions, and was removed without evacuation of its contents. The ovary and fallopian tube were healthy, and were not removed. The aperture in the bladder through which the contents of the cyst had escaped was valvular, and was closed by the compression furnished by the external dressings. The patient died from exhaustion soon after the close of the operation.

Dr. Baer introduced cases from W. L. Atlee, Peaslee, Keith, Geo. F. French, and Goodell, to prove the correctness of the principles upon which he operated.

Dr. W. H. Parish thought Dr. Baer's rules safe and sound; he had removed a suppurating cyst with anterior adhesions. An experienced operator who was present recommended delay; but feeling sure of the correctness of his own principles, he removed the cyst and the patient recovered. In another case in which a fistulous opening discharging pus existed, suppurative peritonitis was diagnosed, but after death from septicæmia, a *post mortem* examination revealed a suppurating cyst of the ovary.

EDITORIAL DEPARTMENT.

PERISCOPE.

Are Phthisis, Bronchitis, and Pneumonia Epidemic Diseases?

Before the Epidemiological Society of London (*Lancet*, April 14, 1883), Dr. G. B. Longstaff read a paper on Phthisis, Bronchitis, and Pneumonia: Are they Epidemic Diseases? The following is an abstract:

The author explained that his object was to examine the Registrar-General's returns in such a way as would make clear their bearing on the solution of the question propounded. As in previous papers, relating to summer diarrhoea and the diseases allied to erysipelas, respectively, he exhibited diagrams graphically representing the death-rates for England and Wales from the diseases in question, and certain others in various ways allied to them, during a period of twenty-five years; also showing the same death-rates in London for thirty-three years, compared with a curve expressing the number of cold days in each winter. Many other curves had been pointed out by the author, but only a few had proved useful for the purpose in hand. One diagram showed

that the death-rate curve of phthisis deviates but very little from a straight line, resembling in this respect those for cancer, apoplexy, paralysis, convulsions, and fractures. The curves of tubercular meningitis (hydrocephalus), and to a less degree tabes mesenterica, resembled the phthisis curve. The phthisis death-rate had fallen 20 per cent. during the last twenty years. The bronchitis curve exhibited considerable fluctuations, but on the average it had risen 81 per cent. during twenty years. Pneumonia gave a curve closely resembling that of bronchitis in many respects, but the average mortality had fallen 20 per cent. The total mortality from all diseases of the respiratory organs, together with phthisis, showed an increase of 5 per cent., indicating that probably many deaths formerly returned as due to phthisis or pneumonia were now classed with bronchitis. Pleurisy appeared to be more allied to rheumatism than to respiratory diseases. From the curves relating to London deaths, it appeared that bronchitis and pneumonia corresponded with the coldness of the winters, but not so closely as might have been expected. Phthisis was but little affected. Curves derived from Messrs. Buchan and Mitchell's paper on the Influ-

ence of Weather on Mortality, showing the average weekly fluctuations of the death-rates from various causes in London during thirty years, strongly confirmed the author's conclusions, with the single exception of *tabes mesenterica*, which gives an entirely different curve from that of phthisis. In another diagram were exhibited the week-to-week fluctuations of the deaths from bronchitis and pneumonia during the last five winters in London, and their relation to cold; also the same for phthisis during two of the winters. This diagram showed clearly that the pneumonia death curve had a general correspondence with the bronchitis death curve; but it differed in two particulars—viz., the fluctuations were much less, and while it rose in the autumn as rapidly, it fell in the spring more gradually. In the spring of 1879 there was a prolonged high mortality from both bronchitis and pneumonia out of proportion to the severity of the cold; and during the whole winter 1878-9 the two curves of bronchitis and pneumonia corresponded less closely than in the others. The effect of two hard winters upon the phthisis mortality was shown to be remarkably slight. It was noted that for every 1000 females who died of pneumonia not less than 1460 males died, whereas in the case of bronchitis the numbers were 1000 females to 1104 males, and in the case of phthisis 1000 females to 1046 males. Bronchitis caused nearly three times as many deaths in proportion to population in Lancashire as in Gloucester. The mortality was also very high in metropolitan Surrey and Middlesex, West Yorkshire, Warwick, and Monmouth. It was very low in Cornwall, Sussex, Norfolk, extra-metropolitan Surrey, Cambridge, and Gloucester. Pneumonia was most fatal in Lancashire, Monmouth, South Wales, West Yorkshire, Stafford, and metropolitan Middlesex and Surrey; least in Sussex, Wilts, Hants, Bucks, Oxford, North Yorkshire, and Westmorland. In eight registration counties pneumonia was found to be comparatively much more fatal than bronchitis—viz., South Wales, Gloucester, Rutland, extra-metropolitan Surrey, Bedford, Cornwall, Monmouth, and Cambridge. In ten registration counties bronchitis was found to be relatively more fatal than pneumonia, viz., North Yorkshire, Warwick, Wilts, metropolitan Surrey, Cumberland, Nottingham, Westmoreland, Cheshire, Somerset, and Oxford. The author's main conclusions were: 1. That the mortality statistics of England and Wales did not give any evidence in favor of the view that phthisis is communicable, but they showed, on the other hand, that weather had very little influence on the phthisis death-rate. 2. That while bronchitis and pneumonia were both greatly influenced by meteorological conditions, it was difficult to explain by those conditions alone all the phenomena. 3. That common catarrh was a communicable disease, and that it was probable that very many cases of bronchitis and pneumonia might be looked upon as complications of that or some similar disease of mild character when uncomplicated. 4. That the different incidence of bronchitis and pneumonia on the two sexes pointed to some difference in the causation of the two diseases. 5. That there would appear to be some common factor in the causation of phthisis and tubercular meningitis.

Excision of the Entire Tongue by Scissors.

Dr. Frederick Treves reports four cases in the *Lancet*, April 21, 1883, in which the entire tongue was removed by what is known as Billroth's method. The procedure adopted in each of these cases was precisely the same; and was briefly as follows: The patient having been anesthetized, the linguals were first secured in the neck. Each vessel was reached by a curved incision that commenced behind a point some little way below the jaw, opposite the anterior edge of the masseter, and that was continued down to the level of the hyoid bone, and finally carried up to a point behind and below the symphysis menti. The sub-maxillary gland having been displaced, the artery was exposed by cutting through the hyoglossus muscle in the floor of a triangle formed above by the ninth nerve, and below by the converging bellies of the digastric muscle. In no instance was there any difficulty in securing the vessel, although, owing to the depth of the incision, the proceeding is somewhat tedious. Care should be taken not to disturb the sub-maxillary gland more than possible, and it is most desirable that no part of the gland should be included in a ligature.

Both arteries having been secured, the mouth is forced open by a Mason's gag, and the tongue drawn forwards by means of a stout ligature passed through its anterior part. The entire organ is then cut out with a pair of strong, straight scissors. The frænum is first freely divided, and one blade of the scissors being thrust beneath the mucous membrane of the floor of the mouth, that structure is divided on each side between tongue and the jaw, as far back as the epiglottis. Returning again to the middle line, the hyoid muscles are divided from before backwards, and, after a few vigorous snips with the scissors, the organ is free. The bleeding that follows is very insignificant, and usually is immediately arrested by firm pressure with a sponge.

For the first three days after the operation the patient is fed entirely through an India-rubber catheter passed into the gullet from the nose. On the fourth day he is able to feed himself, and usually finds it most convenient in swallowing his food to place the head very much to one side, so that the fluid may run by the side of the larynx into the œsophagus. The patient is up on the seventh day, if all goes well, and strong enough to leave the hospital by the tenth or eleventh day after the operation.

He thinks that the following advantages may be claimed for this procedure of Billroth's:

1. It is comparatively simple, and requires no elaborate apparatus.

2. By its means more of the tongue can probably be excised than can be removed by the *écraseur*, no matter how applied. With the *écraseur* it is somewhat difficult to vary the exact amount to be removed in particular cases, since the surgeon can only deal with what can be included in a noose. It may be noted, moreover, that with the scissors an extensive excision can be performed without such complication as division of the jaw or cheek, or an opening into the floor of the mouth above the hyoid bone.

3. The procedure is practically bloodless, and the great source of danger in tongue operations is thus removed. It appears to me that on this

ground Billroth's method is infinitely superior to Mr. Whitehead's modification of the same. Mr. Whitehead, it is well known, removes the tongue with scissors, but without previous ligation of the lingual arteries. The operation has been successful in the skilful hands of the surgeon who introduced it; but it would seem to subject the patient to a totally unnecessary and serious risk—a risk that is not counter-balanced by any other obvious advantage.

4. The wound left after the removal of the tongue is, in a surgical sense, extremely simple, and is actually a clean incised wound. Such a wound must compare favorably with the external charred surface left after the galvanic *écraseur* and with the lacerated wound that follows the use of the cold wire. When the tongue is removed by scissors there are no superficial sloughs to come away from the floor of the mouth, and there is, therefore, less opportunity for the formation of a fetid discharge.

5. The intra-oral part of the operation occupies but a brief space of time, the actual excision requiring probably about two minutes. It is needless to say that when a patient is anesthetized a prolonged operation upon the tongue is objectionable in many ways. The cold wire, if cautiously applied for the removal of the entire tongue, will usually not have cut its way through in thirty minutes.

6. Through the incisions made in the neck the surgeon is enabled to readily remove enlarged glands, and to detect such bodies when they are not to be felt through the skin.

Congestion of the Brain, with Convulsions, Successfully Treated by Venesection.

Mr. Shout, of Chelmsford, writes, in the *Brit. Med. Jour.* :

"The following interesting case has just happened in my practice, which satisfactorily proves that the old disused custom of depletion is, at certain times and in properly diagnosed cases, the only available treatment; and, if judiciously employed, will most likely save life, as was evidenced by the results.

"I was hastily summoned to a young man, aged 21, who had accidentally fallen into the canal, and was supposed to be suffering from the effects of his immersion. I found, on my arrival, that his wet clothes had been changed. He lay upon a couch on his back; the surface of his body was warm; the skin dry, and in its normal condition; his breathing slow; face and neck swollen and congested; pupils semi-dilated, and which did not contract under the stimulus of a strong light; jaws firmly locked; he could not swallow, as a teaspoonful of water ran out of his mouth when given; pulse 100, slow and intermittent; and there was likewise constant spasmodic twitching of the right arm. He could not be aroused from his coma; even tickling the soles of the feet gave no indications of consciousness; there was no paralysis nor rigidity of any part of his body. Mustard plasters were applied to the front of the chest and to the nape of the neck. After a time, he became very violent, opening and shutting his mouth, forcibly protruding the tongue, and endeavoring to bite his arm, which

he seized between his teeth, and it would have been severely injured, had he not been prevented by forcible restraint, it taking several strong men to hold him down during the paroxysms; his face and neck becoming more swollen and turgid, and the convulsions more frequent and urgent every minute.

"I concluded that nothing would relieve him except free depletion, which was at once performed in the usual situation in the left arm. The blood ran very slowly at first, but after a time more freely; it was very dark-colored, which condition continued until the necessary quantity was obtained, the lips becoming blanched, and the pulse more regular. He commenced yawning, and then talking; vomited twice, bringing up some half-digested food; and upon being asked, said he 'never felt better in his life,' and wished to lie down, as he felt very sleepy. Somewhere about twenty-five or thirty ounces of blood was drawn, but the exact quantity was not known, as a common-hand-basin was used for the purpose. He was put to bed, when he slept for two or three hours, after which he awoke much refreshed, and was apparently quite well. He slept well all night; and next morning came to see me, having walked about half a mile. He said he was much better, but the spasmodic twitching of the right arm still continued.

"He gave the following account: Two days previously, he had attended some races, and had been induced to drink more beer than was good for him, having been an abstainer; he had likewise been engaged in wheeling coal from a barge, which he found very heavy work, not being used to it. The sun was, during this time, bright and warm, with a strong north-east wind blowing. He found, on getting up next morning, that his right arm was in continual motion; he could not hold it still. He thought he had delirium tremens; but he still continued at his work, his head feeling giddy and light, and gradually increasing in intensity; he commenced dancing about and performing other antics, not being able to control or direct his movements. He saw the water before him, and all the time thought he was moving backwards and away from it, but instead was going towards it, and into which he fell, its depth being sixteen feet. He found himself at the bottom, and everything he saw appeared enormously enlarged; he came quickly to the surface, and clutched at some reeds, and by the assistance of those present gained the bank, when he became perfectly insensible, and knew no more."

Nitrite of Amyl and Nitro-Glycerine in Uræmic Asthma.

In the *Brit. Med. Jour.* Dr. Sheen, of Cardiff, writes:

"The brief notes I give below illustrate the value of nitrite of amyl and nitro-glycerine in one of the sudden and distressing, though perhaps rare, phases of chronic Bright's disease, viz., uræmic asthma. Nitrite of amyl, acting, probably through the vaso-motor nerves, relaxes the arterioles, and thus reduces blood pressure. As it is very volatile, on the score of economy and convenience, I always carry some of Martindale's capsules in my bag, and these are very handy for

immediate use. Nitro-glycerine is said to have much the same action as nitrite of amyl, and, according to Dr. Mahomed, its great superiority over amyl lies in its gradual and more lasting effect, and the more convenient manner of prescribing it, and it can be taken regularly two or three times a day, or oftener, one minim of a one per cent. alcoholic solution being the usual commencing dose. It is also made up in chocolate tablets, each containing one-hundredth part of a minim; but its action, when given in this form, is not so rapid as that of the alcoholic solution.

"M. P., aged 55, retired from business May 4, 1882. Has been ailing for two weeks, but has been about. Has noticed swelling of the legs towards night for two months, and his face had swollen occasionally for the last month. Has always been careless of his health, and if he got wet, an event which happened not unfrequently, he would never change his clothes. He was taken suddenly ill last evening whilst out walking, about a mile from home, and had to be taken home in a cab. On visiting him at 10 a. m., I found him sitting up in bed, gasping for breath, countenance distressed, and of a sickly pallid hue. Pulse feeble; temperature 98°; tongue pale and sodden; expectoration frothy, with some little blood intermixed; moist *râles* over the whole chest, back and front; urine abundant, clear, containing one-fourth of albumen. At 2 p. m. I found his condition and posture unchanged; he could only speak a few words before he had to stop for breath. He inhaled three minims of nitrite of amyl (a capsule broken in a handkerchief). Within a few minutes his breath was easier, and he was able to recline in bed for the first time since the attack came on, before I left the house. I then put him on nitro-glycerine, one-hundredth of a minim *ter die*.

"May 5. He was lying easily in bed, breathing quietly, and expressing himself as feeling quite well; said he was only waiting till I came before he got up. I cautioned him that his life hung by a thread, and that he could only hope to continue it by the strictest obedience:—unavailing caution. On the 6th he remained in the same condition. The next day he refused to take any more medicine, but promised to stay in the house, a promise which he did not keep. On the 16th he had another attack, and died quietly within thirty-six hours, the urine being loaded with albumen."

Mercurial Decalcification.

From the *Lancet*, April 14, 1883, we learn that a remarkable effect of acute poisoning by mercury, in the form of corrosive sublimate, was discovered by Salkowski, and has been confirmed by Prévost and Frutiger, of Geneva, in a very interesting investigation. The effect is the deposition of calcareous salts in the cortical substance of the kidney. The deposits of lime-salts may easily be confounded with deposits of fat. The process commences in the straight tubules, and afterwards involves the tubuli contorti, and is sometimes so great that the kidneys appear as if petrified. The effect is most marked in the rodents, but may also be observed in the cat, and likewise, although with more difficulty, in the dog, and it is apparently of the same nature in all animals. It is

very remarkable that this change is not, as might be expected, most marked when the poisoning is most chronic. It is greatest when the doses of the poison are such as to cause death in three or four days, and are too small to kill within four-and-twenty hours. The Swiss investigators have made a very important discovery as to the process by which this remarkable effect is produced. They find that the calcification of the kidneys is accompanied by, or rather accompanies, a removal of lime-salts from the bones which, in the case of rabbits, is sufficient to render the epiphyses of the long bones movable on the shafts. In order to estimate the actual amount of decalcification, a series of comparative analyses were made, the tibia being the bone chosen. The loss of lime was found to be usually from two to four per cent., and sometimes to amount even to eight or ten per cent. The change in the bones was always inversely proportioned to the change in the kidney. To obtain even more precise results, the leg of one animal was amputated before the commencement of the experiments, so that the normal proportion of lime-salts might be accurately compared with that present after the action of the corrosive sublimate. But the result of this experiment was the demonstration of a very interesting fact in relation to the processes of calcification and decalcification in the system. It was found that when the animal had recovered perfectly from the effect of the amputation, no mercury having been given, there was an increase in the amount of lime in the opposite tibia. Even after intoxication by mercury, it was found that there was still an excess of lime present, showing that the augmentation due to the amputation of the other leg was more than enough to compensate for the loss produced by the mercury. The peculiar effect of the corrosive sublimate cannot be attributed to impairment of the general nutrition, since in starving animals, which had lost 800 grammes of body weight, the proportion of the mineral constituent of the bone was positively increased instead of being diminished. The rapid decalcification of the bone seems to afford an adequate explanation of the accumulation of lime-salts in the kidneys, arrested in the process of elimination by these organs.

Beri-Beri.

The *Lancet*, April 21, 1883, tells us that the very fact of limitation to a certain part of the surface of the globe lends to the inquiry into the nature of such diseases as beri-beri a suggestiveness which has unfortunately not yet been productive of commensurate results. The relations of beri-beri with other maladies have long been the subject of dispute, and the final solution of the question cannot be said to have been advanced by the most recent contribution to the study of the disease by M. Durodé. The central factors which go to make up the clinical picture of the disorder are anæmia, œdema, and numbness, with paralysis, chiefly affecting the inferior extremities. The disease may run an acute course, or the tedium of its symptoms may be felt over a long period. The profound and rapid anæmia has suggested to many German writers the question of the affinity of the malady with progressive pernicious anæmia. But it seems cer-

tain that we have to do with something more than an idiopathic anemia, and it cannot be said that the association with the progressive pernicious variety would do anything else than render the disease more obscure. The edema would seem to have somewhat special characteristics; it is of rapid onset and of wide extent, and in the final stages dropsy of all the serous cavities, but more especially of the pericardium, has been observed. The stiffness with numbness and palsy of the legs are also strongly marked features. It appears that a residence of more than six months in places where beri-beri is endemic is necessary for the due appearance of the disease. The imbibition of much brackish water also seems to play a part in the causation. The increase of the number of cases in gaols at the end of the rainy season is a remarkable fact, the full explanation of which would probably cast much light on the etiology, as would also the complete *rationale* of the limitation of the remarkably fatal disease to a littoral band of about fifty miles in breadth. The alliances of beri-beri with disorders of the nervous system and with the malarial fevers are also considerable. The disease has been studied more by English than other physicians, and the majority seem to have regarded the affection as an essentially constitutional disorder; and even the most competent of those English observers do not seem to think a more differentiated opinion of the nature of the pathology is possible in the present state of our ignorance.

Some Effects of Nasal Polypi in Children.

A. Jacobi, M. D., in the *New York Medical Journal*, April 7, 1883, relates several cases of obstinate asthma or emphysema in children. The first case was under treatment for some time before the nasal polypus was discovered and removed, when improvement immediately set in. In the second case the nose was examined, a polypus removed; another made its appearance, which was also removed; only ten paroxysms occurred since the removal of the polypi, and these are of a mild type.

"What is the explanation of the relationship existing between the presence of the nasal polypi and the asthmatic attacks, if any such exist?"

It is well known that the presence of any irritation of a mucous membrane will produce effects even at a distance; not a small number of cases of prolapse of the rectum are due to the presence of a polypus situated either upon the sphincter or high up in the rectum.

We often see nasal catarrh coexisting with enlarged nostrils—treatment of the latter curing the former; it is, in fact the result of reflex action.

The doctor also speaks of the relationship between asthma in the adult and the presence of nasal polypi.

Chorea minor, he says, is due almost exclusively to a local irritation of the mucous membrane, associated with chronic nasal pharyngeal catarrh, the chronic symptoms becoming aggravated during acute exacerbations of the catarrh. An intimate relation exists between the nervous system and the nasal mucous membrane; the trigeminus, with all its branches, is subject to direct or reflex irritation, arising from inflamed condition of the nasal mucous membrane.

The thickened mucous membrane or a polypus, in the narrow nasal passages of a child, would seriously interfere with respiration, and hence an accumulation of carbonic acid gas in the brain, particularly about the respiratory centre at the medulla.

The lymphatic system of the nasal mucous membrane and that of the dura mater and the arachnoid membranes are in intimate relations with each other. It will be seen that good reasons have been advanced to show the intimate connection between diseases of the mucous membrane of the nose and cerebral affections.

The Effect of Noise on Healthy and Diseased Ears.

Dr. D. B. St. John Roosa read a paper on this subject before a recent meeting of the New York County Medical Society (*Boston M. and S. Jour.*, May 3, 1883), in which he summed up his experiments somewhat as follows:

(1) A large class of persons suffering from deafness can hear quite distinctly when in a noise.

(2) When this is the case, the disease is situated in the middle ear. The disease is usually of a chronic, non-suppurative character; but the same phenomenon is also noticed sometimes in acute and subacute affections of the middle ear.

(3) The proximate cause of this is not yet definitely determined, but it is believed to depend on the condition of the ossicles.

(4) Boiler makers' deafness is of an altogether different character from the above.

(5) The latter is believed to be due to disease of the labyrinth or the trunk of the acoustic nerve.

(6) Those suffering from boiler makers' deafness do not hear better in a noise.

(7) Cases of impacted cerumen and other affections of the external and middle ear occur in boiler makers as well as in other individuals.

(8) In disease of the labyrinth the tuning-fork C is heard louder and longer through the air than through the bones of the head.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—Two publications on the opium habit are worth the attention of those who would study this form of slavery. One is "Clinical Notes on Opium Addiction," by Dr. J. B. Mattison, of Brooklyn, N. Y.; the other is on the successful treatment of the habit by the *avena sativa*, by Dr. E. H. M. Sell. That a tincture of common oats should turn out to be, as Dr. Sell asserts, "the very best remedy in the distressful, and in many cases, hopeless, malady of the morphine or opium habit," is indeed remarkable.

—Dr. E. E. Montgomery, of this city, in a recent reprint argues against the justifiability of craniotomy on a living child. His presentation of his side of the argument is forcible.

—Of pharmaceutical reprints, the "Review of the Drug Trade of New York for 1882," by Mr. D. C. Robbins, of Yew York, and a discussion of the question: "Is there a necessity for Pharmacy Acts?" by M. G. J. Seabury, are excellent papers.

—*The Inter-Change* is a monthly published by Howard Challen, Philadelphia, the purpose of which is to give all sorts of information concerning books relating to, and periodicals publishing, articles on special subjects. Medicine and hygiene come within its domain. Subscription, \$1 a year.

—A reprint on the "Medico-Legal Relations of Insanity," by Dr. Ira Russell, of Winchendon, Mass., deals largely with the question of insane criminals.

—At the last commencement of the National Medical College, Washington, D. C., addresses were delivered by Prof. A. F. A. King and Dr. Philip G. Wales, U. S. N. These have been published in neat pamphlet form.

—Under the editorship of Dr. Romaine J. Curtiss there has been commenced at Peoria, Ill., a monthly entitled *Home Health*. It is a popular journal on hygiene and sanitary science, and contains original articles and selections. It looks well and promises well, and we hope for it a prosperous career. Price, \$2 a year.

—Dr. G. Reck's "Therapeutischer Almanack" for 1883 contains its usual condensed summary of information on this branch (J. Dalp, Bern, 1883).

BOOK NOTICES.

Brain-Rest. By J. Leonard Corning, M. D. New York. G. P. Putnam's Sons. 12mo. pp. 103.

By "brain-rest" Dr. Corning means *sleep*, and he discusses its vast importance and the means by which it can be obtained. He speaks especially of the value of compression of the carotids as a means of reducing the cerebral circulation, and describes and figures an apparatus he has invented for that purpose. The essay is an ingenious and suggestive one, and merits a careful perusal.

The Microscope and its Revelations. By William B. Carpenter, C. B., M. D., LL. D., etc. Sixth edition. Illustrated. Vol. I. William Wood & Co.

This is the April number of Wood's Library of Standard Medical Authors. It is profusely illustrated, and by an author who always writes both

in an agreeable style and with a full knowledge of his subject.

A Treatise of Practical Instructions in the Medical and Surgical Uses of Electricity. By L. E. Merrill, M. D. Kalamazoo, Mich.

The author of this work is an enthusiast for the miscellaneous and universal uses of electricity in therapeutics. It is lacking in critical judgment, and will be sure to bring about disappointment in those who proceed confidently in many of its recommendations. Nothing is gained to science by lauding electricity as a panacea, or exhibiting it to the exclusion of other modes of cure. The volume seems to be aimed for general perusal, rather than professional, and if so will create in readers hopes of alleviation often doomed to be blasted.

Alcoholic Inebriety from a Medical Standpoint.

With cases from Clinical Records. By Joseph Parrish, M. D. Philadelphia: P. Blakiston, Son & Co, Pp. 185. Price \$1.25.

Few individuals have given such close attention to the study of inebriety as Dr. Parrish. With him it has been the main interest of his professional life. His matured views, as they are presented in this work, must command the close consideration of all who would solve or try to solve the hideous enigma of intemperance.

Evidently the author leans strongly to the belief that in very many cases persistent drunkenness is a disease which must be treated, and may be cured, as are other diseases. On one point we could wish he had been more definite. The distinction between inebriates and moderate or even "heavy" drinkers is not clearly drawn, and hence many of the statistical assertions are less accurate than they might be.

The subjects discussed are, who are inebriates, inebriety a disease, traumatic and hereditary inebriety, the relations of inebriety to insanity, inebriate asylums, their management, the different alcohols and their effects, and the psychology of inebriety. On all these the reader will find excellent material and carefully digested observations.

—A man went into a drug store, and asked for something to cure a headache. The druggist held a bottle of hartshorn to his nose, and he was nearly overpowered by its pungency. As soon as he recovered, he began to rail at the druggist, and threatened to punch his head. "But didn't it help your headache?" asked the apothecary. "Help my headache!" gasped the man. "I haven't any headache. It's my wife that's got the headache."

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

KATATONIA.

By this term is to be understood, so Dr. Wm. A. Hammond says in the *N. Y. Med. Jour.*, May 5, 1883, a form of insanity first described by Kahlbaum, and characterized by alternate periods supervening with more or less regularity, of acute mania, melancholia, and epileptoid and cataleptoid states, with delusions of an exalted character and a tendency to dramatism.

Several cases from his practice are cited.

A merchant presented the first symptoms by a condition of exaltation; he entered the office with all the air of a prince, and answered all questions by repeating in a supercilious way, "And the Lord spake unto Moses, saying." This he repeated during the entire visit. By inquiring I learned, however, that eight days previously, without any assignable cause, he had passed into a condition of melancholia, with stupor. By extending his arm at right angles to his side, it was noticed that it remained in that position for thirteen minutes, and then descended slowly to his side. Ophthalmoscopic examination being demanded, the patient would not enter the dark room. Upon endeavoring to carry him there, he at once became as rigid as a bar of iron—his muscles were in a state of extreme tension.

The next case, a young German, exhibited the cataleptoid state, and a tendency to utter high-flown language, and to assume histrionic attitudes, exclaiming at intervals, "My lord, it shall be done!" He had passed through the stage of melancholy before presenting himself.

He frequently cried and groaned, said afterwards that the reason he did not speak was because he had the idea that it had been decreed that if he uttered a single word, his mother would at once die.

The third case was a physician. When seen he was in the stage of melancholia with stupor, attended with cataleptoid symptoms. If physical efforts were used, his whole muscular system was thrown into extreme tension. He appeared to be in a condition not unlike a person suffering from tetanus. Another case, a Swede, age 30, presented much the same symptoms as the former cases.

The doctor says that many cases of unrecognized katatonia are to be found reported in writings on psychological medicine.

The disease is more common in men than in women.

"Katatonia is of rather favorable prognosis. It appears in the first stage, at least, to be a vaso-motor affection characterized by a paralysis of the vascular coats, and by consequent cerebral hyperæmia."

All his cases except one yielded readily to the bromide of sodium; that patient did not get the medicine prescribed.

ANCIENT ROME AND THE CAMPAGNA.

Dr. Drummond, of Rome, recently delivered a lecture before the British and American Archæological Society of that city, on the "Climate of Ancient Rome," in which we have the same old story told again.

Unused organic remains producing disease.

From the historical fields of ancient Rome, as from our own new country, comes ever forth the imperious mandate, *unto dust thou must return*, not figuratively, but absolutely.

From these soul-stirring campagnas, we read the same lessons that sanitarians of to-day are teaching.

Dr. Drummond very sensibly argues that the ancient Romans must have been a healthy race, else their wonderful physical achievements would have been impossible; and with equal reason he concludes that this health was due to their belief in hygiene and sanitary matters; to their athletic sports and their unparalleled baths.

The malaria of the campagna, he attributes to systematic neglect of proper drainage and cultivation.

Here it is again: the old lesson.

This campagna was once thickly inhabited with organic life; it died, and for centuries has been lying, decomposed and unused, save to poison the atmosphere. The experiments or experience within a short time of the Trappist monks, who are cultivating certain portions of the campagna,

is that they have rendered their vicinity free from atmospheric poison.

Does not this experience teach us, that the rotatory life of atoms is an essential to healthy surroundings; from vegetable life, directly, as well as indirectly, through the lower animals to man, and from man back to the vegetable kingdom and so on?

Any interference with this rotation, any delay on the part of these elements, in their journey, renders them more or less inimical to healthy animal life, since it disarranges the beautiful economy of nature.

Let us learn the lesson, and ponder well over it.

L' HOPITAL DES ENFANTS ASSISTÉS A PARIS.

A very interesting report on this large and important institution was recently presented to the Ministre de l'Interieur by MM. Lunier and Foville.

This hospital admits from five to nine thousand children annually, but as many of them remain but a short time in the institution, from twenty to thirty are admitted or discharged daily. Usually there are from 350 to 400 children in the hospice. The ages vary from a few days to twelve years or over. In 1881, 1,758 under one month old were admitted, 906 from one month to one year, and 1,628 from six to twelve years old. The Enfants-Assistés are children presented by their families to be abandoned (à la Jean-Jacques Rousseau), and others found in the streets or left in the hands of nurses. Another class, the Enfants-Secourus, are children at first abandoned by their parents, but returned to them with a small government allowance to enable them to bring them up.

The commissioners very warmly recommend isolation of contagious diseases, which is impossible in the present condition of the hospice. According to M. Lunier, one-third, at least, of the children who die in the institution contract in the wards the contagious disease to which they succumb. Diphtheria is so prevalent and so malignant as to have caused the death of two very distinguished chefs-de-clinique, who were obliged to make direct applications to the throat.

An unique feature of the institution is the

nursing service for syphilitic infants, established by M. Parrot. The nurslings draw their nourishment directly from the teats of the ass, to which they are presented five times during the day and three times at night. They thrive under this treatment, and 70 per cent. live, while almost all formerly died when fed from the bottle.

COLD BATHS IN TYPHOID FEVER.

In the recent lengthy and desultory discussion on the treatment of typhoid fever in the French Academy, the method by cold baths provoked considerable discussion.

Prof. Bonley was the defender of Brand's method, bringing forward in support of his views statistics obtained through the French ambassador at Berlin. M. Ricklin has since reviewed the statistics obtained, and arrived at the following conclusions:

Brand claims that the average mortality before the introduction of the refrigerant treatment was as high as twenty-one per cent., and that under the influence of this method it has fallen to seven per cent. In support of this assertion, in the last edition of his work (*Die Wasser Behandlung der Typhösen Fieber*, 1877,) he gives statistics founded on 355 cases observed in his own practice, with fifteen deaths, an average mortality of less than five per cent.

But on consideration of the cases we find that 211 occurred in his private practice without a single death; so that among the remaining hospital patients, 124 in number, fifteen deaths took place, making the real mortality in the cases adduced by Brand twelve per cent.

Closer examination of the statistics presented by the German authors in support of this method, show that the average mortality in Schmidt's service at Erlangen was nineteen per cent.; in the Rudolph Hospital, at Berlin, from fifteen to thirty per cent.; in the Bethany Hospital, where the method was systematically carried out by M. Goltdammer, from ten to sixteen per cent.; in Stricker's service, seventeen per cent., and so on in all the hospitals of Berlin where this method of treatment was most rigorously carried out.

NOTES AND COMMENTS.

Irregular Contractions of Uterus a Source of Danger After Labor.

In the *Med. Times and Gaz.*, April 28, 1883, Dr. William Alexander calls special attention to this condition, and indicates its dangers and its relief with the following cases:

"Some years ago a patient in the lying-in wards had my attention called to her three days after delivery on account of her feverish and restless condition. I found a firm round tumor in the right iliac region, about the size of an adult human head. It was very tender, and was freely movable. Next day peritonitis had set in, and the tumor was much less distinct. Poulitices were used, and the usual treatment of those days, but the patient died. The uterus had contracted irregularly, and had become tilted into the iliac fossa, so that drainage could not be carried out. About six months ago I saw a similar case in private, accompanied by much fever and such an appearance of the patient that the ordinary medical attendant thought it was "all up" with her. Having by this time unraveled the true pathology of such cases, I grasped the uterus gently, and by gradual pressure caused it to contract and to expel a considerable quantity of discharge. A little pain was produced at first, but this soon subsided, and before I left the house the patient expressed herself as much relieved. In the first case, the old treatment—poulitices to the abdomen, sudorifics, anti-pyretic vascular sedatives were used—remedies that I believe increased rather than diminished the mischief. Antiseptic syringings of the uterus and vagina are the only rational treatment hitherto employed; but these syringings were rarely complete, and seldom passed beyond the vagina. The amount of pressure must be reasonable, for harm might be done by doing too much, and practically is rarely required in my hospital practice, because of the efficient way in which the binder is applied. Its application is, I believe, one of the most important subjects in midwifery, and it is applied by my nurses in the following manner: The uterus is first ascertained to be well contracted, and at least in the entrance of the pelvis. A broad and substantial pad is applied over that organ, and kept in its place by a strong twilled calico binder that reaches from the great trochanters to the eighth or ninth ribs. This binder is drawn as tight as the patient can bear with comfort, and is watched, and readjusted if necessary several times in the day. I make it my business to see that

the binders are properly applied, the patients and napkins clean, and the wards pure. Nothing else requires to be done except to pass my hand over the abdomen, generally outside the binder, in a small percentage of cases who show high temperature."

An Inquiry into the Causes of the Increase of Cancer.

At the end of a long and elaborate thesis on this question, Mr. Dunn concludes (*Brit. Med. Jour.*):

"1. That, in the face of incontrovertible facts, cancer is increasing in England.

"2. That this increase is due (a) To the success attending the legislative measure and other means for the preservation of the infant population, by which a large proportion of persons reach adult age, and the general healthiness of the community is increased. (b) To the greater prominence which, in the present day, prevails, of the most predisposing causes of the disease—such as the fecundity of women, the prevalence of high nervous tension, the existence of possibly greater general luxury in the mode of living.

"3. That the immunity apparently demonstrated by the records as present in certain counties of England and Wales, is presumably, as we have attempted to show, not due to any real declination of the disease, but rather to such causes as can be explained by special local predisposition to other diseases, to which a large proportion of the adult population succumb.

"4. That in consequence of this, if each district of England and Wales were equally healthy, each would probably exhibit a high cancer mortality.

"5. That the geographical area of which England and Wales is composed, is insufficient to account directly for interruption in the distribution of cancer as met with in this island."

Alcoholism a Cause of Sterility.

In the course of the Gulstonian Lectures on Sterility (*Brit. Med. Jour.*, April 21, 1883), Dr. J. Matthews Duncans attributes a causative influence to the free use of alcohol. He says, "The immoderately great consumption of alcoholic drinks by women, without their necessarily ever reaching the stage of drunkenness, is so common and so potent a cause of disorder and disease, that it requires special mention. It is possible that much of the influence of this drinking might be justly ranked as part of mere overfeeding, whose injurious effects we have already spoken of; but this is

far from certain. Indeed, while I am unable to give any strong evidence of the specially injurious action of alcohol, considered as an article of diet, I am much disposed to this view, being led to it by the good results in practice which I believe justly attributable to desisting from the use of it. But alcoholic drinking has, in addition to the general or constitutional disorder which it produces, well ascertained power, in certain cases, to induce disease of the internal genital organs. That which is most easily and distinctly made out is chronic ovaritis. It often comes and goes in the presence or absence of the cause. When it is present, sterility is not always a result, but frequently so, and its cure is often followed by the disappearance of the sterility."

Presence of Phosphate of Magnesium in the Urine of Persons suffering from Affections of the Stomach.

A man, æt. 49, suffering from a chronic affection of the stomach (dyspepsia, constipation, frequent vomiting), discharged urine which was free from albumen and a sediment, but was alkaline, and whose reaction was caused by a fixed alkali. Letting the urine stand for five days in a warm room had not made it ammoniacal as yet, but there now appeared a sediment of transparent crystals (four-sided prisms), which by their shape, as well as by their reaction to carbonate of ammonia (opaque and stripes, especially in the longitudinal direction) proved themselves to consist of phosphate of magnesium. Such a sediment formation out of an alkaline urine (whose reaction in this case was caused by frequent vomiting and the abstraction of acid from the system necessarily connected with it) seems to be very rare, and to happen then only, when after letting the urine stand for a number of days, the decomposition of urea into carbonate of ammonia, and the formation, connected therewith) of phosphate of ammonia—magnesia has not taken place. As the occurrence is so rare, and can be caused only under the circumstances mentioned, it may be possible that the fact, by further investigations, may become an important one in the always difficult diagnosis of certain obscure diseases of the main organ of digestion. (*Deutsch Arch. of Klin. Med.*, xxxi., p. 203.)

Lacerations of Cervix Uteri.

Dr. Mary A. Smith contributes to the *Boston Med. and Surg. Jour.*, April 5, 1883, the statistics of operations for this accident occurring in the New England Hospital for the two years beginning October 1, 1880. Only such cases are reported as

were of sufficient gravity to require surgical interference. There were forty cases, fifteen in primiparæ and twenty-five in multiparæ. Thirty-seven were operated upon thirty-nine times, three yielding to non-surgical treatment.

An Explanation of Inhibited Development.

A Case of Perobrachy Explained.

A railroad laborer, æt. 40, who was fatally injured by an accident, and who had been affected all his lifetime (being born that way) with a want of development of his right lower arm and hand, gave Dr. L. Davida (Centrbl. f. d. Med. Wiss., 48, 82, p. 879) a good opportunity of studying the morbid condition of his nervous system accurately. D. found that from the sixth cervical nerve to the first thoracic nerve, the anterior as well as the posterior roots contained a decidedly smaller number of nerve fibres on the right than those on the left side. The spinal ganglia on the right side were also smaller than those on the left, and the anterior branches thinner than on the healthy side.

The explanation would seem natural, that this condition of things caused the perobrachy. This is the opinion of Davida. But we believe that in the brain the real cause would have been found. The abnormal condition in the spinal cord simply showed the same status which we always find whenever an extremity, or a part of one, or a

muscle, or a set of muscles, has not continually exercised its normal function. In such cases, the spinal origin of the respective nerves becomes atrophied, dwindles away. Why would we find such lesions in persons who all their life had a perfect use of their limbs, and who some years before their death were by an accident, or by paralysis, or amputation, deprived of their use?

Hæmorrhage from the Lachrymal Duct During Epistaxis.

Mr. D. Hoadley Gabb, M. R. C. S., of Hastings, describes the following remarkable case in the *British Medical Journal*:

"Mr. S., aged 50, with mitral disease and albuminuria, sat out one of our recent sunny days, and caught a chill, which culminated in an attack of bronchitis and a relaxed state of the fauces and uvula, producing severe spasmodic cough; during one of these paroxysms, epistaxis, from the right nostril especially, came on rather profusely, and I was sent for. There was no difficulty in arresting it by plugging the anterior nares with dry lint. In two or three hours, after a severe cough, the hæmorrhage returned, and a messenger was sent for me, saying the bleeding had come back, and was running out of his nose and eyes; and so I found that the blood had welled up through the right lachrymal duct, and was suffusing his eye, so that he was constantly obliged to wipe it, and the handkerchief was pretty well stained with the blood, and the discharge only ceased when the nose left off. I have never met with the phenomenon before, neither have others to whom I have mentioned it; and so, I think, perhaps it is worth recording."

The Treatment of Parturition and the Parturient State in Hospital Practice.

Commenting on the fact that nature unaided deals much more leniently with the parturient woman, at any rate among the lower classes, than when she is aided by the highest medical skill and with all the appliances of hospital treatment, Dr. William Alexander, in the *Medical Times and Gazette*, April 7, 1883, raises his voice against *meddlesome* midwifery. He deprecates unnecessary examinations, lest our fingers may introduce septic material, and urges us to give nature a fair chance to expel the placenta before we interfere. He again urges cleanliness as the great desideratum, and considers that the proper kind of a bed for a lying-in hospital is one made of clean straw, retained in an easily-washed sack of coarse ticking; a double blanket will make it sufficiently soft. At

the end of twenty-four hours the patient is transferred to the lying-in bed, another new straw bed of larger dimensions. This the patient occupies for a week, when she is transferred to another new bed in the convalescent ward. The ticks are thoroughly washed, and the same straw is never used twice in the *lying-in wards*. From these suggestions we can derive some hints for our guidance in private practice.

Lister and the Spray.

Dr. Henry Gray Croly publishes the following letter from Mr. Lister on this subject in the *Medical Press*, April 25, 1883:

"I have not given up the use of the spray, although I certainly regard it as the least important part of our antiseptic arrangements. Whatever other good it may do, it is a very mild form of antiseptic irrigation, and tends to keep the *entourage* of the wound, including the surgeon's hands and instruments, pure. But if I had not a spray-producer at hand, I should not on that account omit other elements of antiseptic treatment. I still use the spray in changing dressings, so long as the wound is not merely superficial. But far more important than using the spray is it to make a point of covering the wound with some pure aseptic material before beginning to wash the parts which were covered with the edge of the dressing only, and were, therefore, impure. In other words, I believe one of the commonest causes of failure is dabbing alternately the impure surrounding parts and the pure wound with the same piece of rag, which, though moistened with carbolic lotion, cannot work miracles."

Compound, Comminuted Fracture of Skull; Trephining; Recovery.

Dr. A. D. Murray reports a case in the *Lancet*, April 28, 1883. The operation was performed in the usual way. A little more than half a circle was removed from the sound bone above the apex of the triangular depressed portion, and after a corner had been removed by means of the saw, the piece was easily lifted out; a clot was found under this. The middle meningeal could be seen pulsating at the lower corner, but was uninjured. Some fragments were taken away, the wound dressed with carbolic oil and washed frequently with carbolic spray. The man made an excellent recovery, never having had a bad symptom.

He thinks that this case points strongly to the advisability of trephining at once in compound comminuted depressed fracture of the skull, without waiting for symptoms of compression.

The operation does not add to the patient's danger, and may, in all probability, be the means of preventing serious complications.

Sub-periosteal Amputation at Hip-joint.

Before the Clinical Society of London (*Medical Times and Gazette*, April 14, 1883), Mr. Howard Marsh read the report on Mr. Shuter's case of subperiosteal amputation at the hip-joint which was signed by Messrs. Croft, Marsh, Clement, Lucas, and Shuter. The report went to show that it was doubtful whether any amount of bone was present in the central cord of firm resisting tissue, that it was true that the muscles were in a high state of nutrition, and were able to give the stump and an artificial limb independent motion. The committee also decided that in the operation performed there was diminution in the risk from hæmorrhage, with preservation of muscles of such a length as would correspond to that obtained by an amputation through the upper third of the thigh; it was also found that the periosteum had been stripped off as high as the trochanters.

The Coat-Sleeve Amputation.

Some time since we referred to this operation of Mr. Davy's (*Brit. Med. Jour.*, June 17, 1882), in which a circular incision is made, the tissues dissected up, the bone sawed through, and the tissues brought together as one would the end of the coat-sleeve. Dr. L. Colbourne, of Buenos Ayres, writes to the *Brit. Med. Jour.*, April 7, 1883, that having occasion to amputate the leg of a fairly muscular man, he found it impossible to turn the tissues up, when the diameter of the leg was (as in robust people, it always will be) greater above than at the point of incision. To obviate this difficulty, he made a longitudinal incision in the posterior aspect of the flap.

The Deligation of Large Arteries by the Application of two Ligatures and the Division of the Vessel Between Them.

Attention is called by Dr. W. J. Walsham, in the *Brit. Med. Jour.*, April 7, 1883, to the fact that secondary hæmorrhage, after ligation of arteries, is often due to the fact that in separating the sheath from the artery, the blood supply of the latter is cut off, and sloughing or gangrene of the vessel in the vicinity of the ligature results. To obviate this danger he recommends applying two ligatures, about half an inch apart, the denuded and devitalized portion of the vessel being thus between them, and dividing the vessel in this portion.

The Benzoates in the Uric Acid Diathesis.

In the course of the Lumleian lectures on uric acid, Dr. Alfred Baring Garrod states (*Brit. Med. Jour.*, April 21, 1883), that the Benzoates possess the power of causing the disappearance of uric acid from the urine. He frequently uses benzoate of sodium, and if at the same time he desires to increase the quantity of the urinary secretion, he gives the benzoate of potassium or lithium. He is directing his researches towards the formulating of some food sufficiently rich in hippuric acid as to keep in check the tendency to form and deposit uric acid.

Salicylic Hair Tonic.

A correspondent of the *Druggists' Circular* recommends the following as the best remedy against dandruff, itching of the scalp, and falling of the hair:

Borate of soda	10 drachms.
Salicylic acid	10 scruples.
Tincture of cantharides	6 ounces.
Bay rum	25 "
Rose water	25 "
Boiling water, enough to make	4½ pints.

Dissolve the borax and the acid in boiling water; mix the bay rum and rose water with the solution; then add the rest, and filter.

Spasm of Eyelids and Ciliary Muscles with Intense Pain, Caused by Exposure to Electric Light.

Dr. A. T. Thomson reports in the *Med. Times and Gaz.*, April 14, 1883, the case of a man aged twenty-five, who on two different occasions neglected to wear his eye-protectors when working about an electric light. In both instances, some three hours after the exposure, violent pain, so intense as to prevent sleep, came on in both eyes, and he lost control over the eyelids, which remained rigidly closed. Free instillation of solution of atropine gave prompt relief.

Balano-posthitis of Diabetics.

For this trouble Prof. Simon specially recommends cleanliness, and after each micturition, lotions feebly charged with phenol, and after drying the part, powdering it with the following:

R. Oxide of zinc	25 parts.
Starch	25 parts.
M. Salicylic acid	1 part.

Iodine for Vomiting.

Dr. T. T. Guant (*American Journal of the Medical Sciences* for April, 1883,) has for a number of years been employing the compound tincture of iodine in drop doses in nearly all forms of emesis,

and reports thirteen cases of the most varied character, in all of which vomiting was promptly arrested by its use.

Oxide of Zinc in Chronic Diarrhœa.

M. Gubler has found it most useful in the diarrhœa of phthisis, and whenever ulceration of the uterus is suspected. He gives it in powders in the following form: Oxide of zinc, thirty grains; bicarbonate of soda, ten grains; in four powders, two or three daily.

Fatal Shock from Supposed Snake Bite.

That imagination may prove fatal, receives fresh proof from the case reported in the *Med. Press*, April 25, 1883, by Dr. C. R. Francis. The patient, awakened from his sleep by something creeping over his naked legs, immediately jumped to the conclusion that it was a cobra, went into a state of collapse, and died, though it was discovered, even before death, that the supposed cobra was a harmless lizard.

Salicylic Acid for Venereal Warts and Ulcers.

Dr. Solon D. Stone (*Boston M. and S. Jour.*, April 26, 1883), has had very good results. His method is to fill, or pack, an ulcer with the acid which he keeps constantly applied until there is a healthy granulating surface. For a few minutes following the application of the acid to a raw surface the pain is quite severe, but it soon subsides.

Occlusion of Vessels by Oil.

Dr. Handfield Jones believes (*Brit. Med. Jour.*, April 21, 1883), that in atheromatous conditions of the small vessels of the brain, and presumably also of other organs, the degeneration of the patches of atheroma lead to the formation of oily masses within the lumen of the vessel, and so to obstruction.

Incision into and Drainage of the Pericardium.

Dr. Samuel West has performed this operation for the first time in England in a case of purulent pericarditis. The *Med. Times and Gaz.*, April 28, 1883, tells us that it was a great success; there is no deformity of the chest, and only a very small scar remains.

Hamamelis in Varicose Veins.

Dr. J. H. Musser has procured good results in a number of cases of varicose veins from the use of fluid extract of hamamelis in teaspoonful doses. The cases are recorded in the *Medical Times*, April 21, 1883.

CORRESPONDENCE.

Pepsin Preparations.

EDS. MED. AND SURG. REPORTER:—

I have this day tested a specimen of Dr. Jensen's so-called "crystal pepsin," with the following results, which may be of interest to your readers:

Experiment 1. One-quarter of a grain of Jensen's pepsin dissolved in f. 3 iss. of water mixed with f. 3 lj. of water containing 9 drops of hydrochloric acid, and kept at a heat varying from 100° to 110° F., dissolved 125 grains of hard-boiled white of egg in two hours.

Experiment 2 was an exact copy of the first, except that solution was effected in two and a quarter hours.

Experiment 3. One-quarter of a grain of the same pepsin, under like conditions, dissolved 150 grains, or 600 times its weight, of coagulated albumen, in about three hours—this amount of albumen being rather more than half that usually found in an egg of average size.

Experiment 4. One-quarter of a grain of the pepsin similarly tested with 200 grains of boiled white of egg, left a small residue (estimated to weigh 20 or 25 grains) at the end of three and a half hours, when the experiment was interrupted. It was therefore probably capable under these circumstances of dissolving at least 700 times its own weight of freshly coagulated albumen.

The solvent power of this pepsin is thus shown in these investigations of mine to be not less than twelve times as great as that of the "pepsinum saccharatum" (U. S. Pharm. 1880), and hence this method of preparing pepsin unquestionably places within the reach of physicians a vastly improved means for aiding the stomach digestion of nitrogenous foods.

Jos. G. RICHARDSON, M. D.,
Prof. of Hygiene in the University of Pennsylvania.
Philadelphia, May 16.

NEWS AND MISCELLANY.

American Laryngological Association.

The Fifth Annual Congress of the American Laryngological Association was called to order in the hall of the New York Academy of Medicine, at 10 o'clock, on Monday, May 21, by George M. Lefferts, M. D., President of the Association.

After delivering his annual address, the President, Dr. George M. Lefferts, read a paper detailing new facts in laryngology.

S. W. Langmaid, M. D., of Boston, called attention to a common form of vocal disability resulting from pathological processes, the phenomena being used to demonstrate the falsity of one system of voice training. He had observed a class of patients who are in the habit of making considerable use of their voice, who complain that at a certain point in singing the scale a break occurs in their voice; below this their normal tones are preserved. He attributed this condition to fatigue of the vocal apparatus, caused by fatigue following over-exertion. It not infrequently results from sudden cessation of singing

after excessive use of the voice, and is more likely to occur in those filling a leading rôle than in the subordinate parts.

A paper on the

DESTRUCTION OF NASAL POLYPI BY CHROMIC ACID

was read by Frank Donaldson, M. D., who said that the object of treatment in cases of mucous polyp is to remove the growths with as little discomfort as possible, and to prevent their return. Of the three methods in use—evulsion, abscission, and the electric cautery, each had its advocates and its advantages, and each its disadvantages. Evulsion causes pain, and is often inefficient to prevent their return; the removal by the snare or wire loop is open to the same objection, unless the origin of the growth is cauterized, or part of the underlying structure, including the bone, is removed, as recommended by Mackenzie. Of the caustics, in his experience, chromic acid deserved the preference. His manner of employing it is to protect the surrounding mucous membrane with a lead solution, and part of the paste is then taken up on a glass rod and buried in the polyp, which shortly afterward dries up, and is easily removed with the forceps or snare. With chromic acid we can touch the exact point of origin of the growth; and it is useful in both forms of polypi, in gelatinoid and adenomatous. In the fibrous polyp it is less efficient, because they extend frequently to the naso-pharyngeal cavity. It is not intended to substitute chromic acid for surgical procedures, but it is effective as an aid to them, facilitating their action by destroying the substance of the neoplasm, by making the operation less painful, less bloody, and by supplementing their action in destroying the insertion of the growth, and thus preventing their reformation.

Dr. F. I. Knight, of Boston, then read a paper on

CHOREA LARYNGIS,

in which he first directed attention to the close relation existing between chorea and hysteria. The object of the paper was to call attention to the different kinds of cases which have been reported as chorea laryngis, and to invite discussion upon the same. Chorea laryngis was probably but one of the many manifestations of a general affection. There were three varieties which had been described. First, that in which not only the abductors of the larynx were involved, but the expiratory muscles of the chest are affected, characterized by cough occurring in paroxysms, accompanied with more or less vocal sound, the barking or crowing character of the cough sometimes occurring suddenly, sometimes at particular periods of the day, usually affecting patients between eight and fourteen years of age—these were the leading symptoms mentioned. On examination of the larynx in these cases, only structural changes were discovered. The second class of cases were those in which the muscles of the larynx alone had been affected, particularly the hyothyroid muscle. The author of the paper then reported one case of chorea of the abductors of the larynx without any affection of the expiratory muscles, and hence no effort at coughing. In this case there was a peculiar ticking in the head which the patient heard and which he could hear, and which he identified as a clicking to-

gether of the vocal cords. He believed that it was a unique case, at least it was in his experience, and, so far as he had been able to find, in literature; that is, a case in which the spasm was rhythmical, and in which it continued during sleep. Third, and which did not, strictly speaking, belong under the head of chorea laryngis, those cases in which the expiratory muscles alone were affected.

Dr. E. Fletcher Ingals, of Chicago, then read a paper on

THE TREATMENT OF LARYNGEAL PHTHISIS.

There are three prominent indications: First, to relieve pain; second, if possible to cure the disease; and, third, failing in either of these, to modify the course of the affection and prolong the patient's life. He believed that these indications could be met successfully in quite a proportion of cases. Pain can generally be relieved by topical applications, even though internal medication is of but little avail. The second indication is met best by the combined topical and internal medication. In the third place, we may succeed in modifying or relieving pain, and enabling the patient to swallow, and so prolong life. Dr. Ingals then gave the history of a few cases which illustrated that the indications mentioned could be satisfactorily fulfilled. He recited the history of two cases which illustrated that laryngeal phthisis can be cured when the pulmonary complications are improving. One favorite local application which he had employed was a combination of carbolic acid, morphia, and tannic acid. He had used eucalyptol with benefit in several cases. In his hands iodoform had given but little or no relief from pain, and had failed to produce any perceptible curative effect. His conclusions were that we may meet the first indication better by topical applications than by any other means, and that we may confidently expect to give relief in a considerable proportion of cases. Second, that a limited proportion of cases may be cured by local and general treatment, the former sometimes being the most important factor. Third, that in many fatal cases life may be prolonged by local applications which relieve the patient from the exhaustion of the pain and irritating cough, and at the same time allow digestion of food.

Dr. Wm. C. Jarvis, of New York, read a paper, entitled

THE HEALING OF ULCERS IN LARYNGEAL PHTHISIS.

He premised his remarks with a reference to the incredulity of the medical profession regarding the cure of laryngeal phthisis. This was in part due to fragmentary histories of cases reported, insufficient evidence, and claims for cure based upon peculiar methods of treatment. The history of a case was recited in which the phthisical ulcers had been entirely healed. The evidence of physicians and specialist from whence the case came, demonstrated conclusively advanced laryngeal phthisis. The lungs had been examined by experts, and coexisting pulmonary phthisis discovered. The treatment was explained in detail. It consisted locally in the frequent use of fine, unirritating sprays; atomized alkaline fluids were employed for cleansing; local sedation was practised, and iodoform freely used. Constitutional medication was considered of much importance to quiet

cough and favor cicatrization, promote sleep, relieve restlessness, and to nurse and nourish the enfeebled body. Change of climate was also considered essential. By carefully combining these means, a patient threatened with death by starvation from painful deglutition, was restored to strength and comfort. One vocal cord had been almost entirely eaten away, firm cicatricial tissue forming the excavation.

He showed there was an analogy between certain forms of phthisical ulcers in the larynx, and simple superficial ulcers in the mouth; that sores in the mouth were sometimes produced by the irritant action of perverted buccal secretions upon slight wounds. A pellicle of shellac varnish, or an eschar, afforded protection and facilitated healing. If the lesion happened upon a part in frequent motion, it was converted into a severe ulcer, producing a train of constitutional symptoms resembling in certain respects those of ulcerative laryngeal phthisis. He believed the incipient wound of phthisical ulcers could be caused by a violent cough; constant motion, and acrid discharges from the lungs, completed the analogy. Certain forms of phthisical ulcers, easily recognizable, could be cured. Far-advanced phthisical ulcerations invariably proved fatal.

Dr. F. H. Bosworth, of New York, then read a paper entitled

PARESIS OF THE CONSTRUCTOR MUSCLES OF THE PHARYNX, SIMULATING SPASMODIC STRICTURE OF THE ŒSOPHAGUS, WITH REPORT OF CASES.

The histories of five cases were given, which illustrated the myopathic affection, what we had been taught to regard a myopathic paralysis, neurotic in character. Dr. Bosworth believed that the affection was essentially muscular, and could be best explained by the general law that muscles which are overworked show a tendency to break down, and this tendency is especially marked if they are situated just beneath a diseased mucous membrane. The author of the paper then spoke of the inherent tendency in certain muscles of the larynx to become the seat of myopathic paresis. His cases were treated with rest, strychnia, salt-water bathing, etc., and all the patients except one recovered.

Dr. Cohen, of Philadelphia, regarded this class of cases as essentially hysterical, certainly the majority of them as they had occurred in his practice. He had obtained the greatest success by placing a nurse over the patient and insisting that food should be swallowed.

Dr. Langmaid, of Boston, had had the best success in their treatment by passing bougies, beginning with a very small one, and advancing gradually to one of large size,

Dr. Knight, of Boston, had had similar cases, but there was no loss of electro-muscular contractility. He had felt that in most cases the difficulty was due to hyperæsthesia, and was best overcome very much in the way mentioned by Dr. Langmaid.

Dr. Bosworth said the question of hysteria was excluded in his cases, because there was unquestionable sluggishness of the muscles, and anæsthesia when touched with the probe.

The Association then adjourned to meet at 11 a. m., on Tuesday, May 22.

The annual dinner of the Association was given at Delmonico's, in the evening at 7 o'clock.

SECOND DAY.

Dr. T. R. French, of Brooklyn, read a paper on

PHOTOGRAPHING THE LARYNX,

which concluded as follows:

The results of the experiments made this year may be summed up as follows:

1. Better photographs have been taken with the stationary apparatus than those of last year.

2. A camera has been so adapted that it can be held in the hand and be quickly placed in position. This makes it possible to photograph the larynx in patients whose fauces are only moderately tolerant.

3. The photographs are taken instantaneously by a drop-shutter, thus making it possible to photograph the larynx even if the parts are in motion.

4. The parts reflected in the mirror are alone exposed, thus avoiding the confusion which arises when the mouth and lips are included and out of focus.

5. As the apparatus is so small, and the exposure is made instantaneously, if desirable, photographs can be taken without the patient being aware of the object of the procedure.

6. Several diseased conditions of the larynx have been photographed. This is an important step in advance, for we believe that it is the first time that it has been accomplished.

7. Portions of the rhinoscopic image have been photographed.

The photographs show, among other things, hypertrophy of the mucous membrane covering the posterior portion of the nasal septum. So far as we are aware, this is the first time that any portion of the posterior nares has been photographed.

Dr. H. A. Johnson, of Chicago, reported five cases of congenital tumor of the larynx.

Dr. Wm. Porter, of St. Louis, communicated a paper on

LARYNGEAL PARALYSIS FROM ANEURISM.

Laryngeal paralysis, he said, though a common sequence of thoracic aneurism, is not always the first evidence of the lesion. He presented notes of three cases in which the patients had, when first seen, no other subjective symptoms than those caused by the laryngeal condition.

The first had hoarseness and slight dyspnoea for two months, gradually increasing. There were no evidences of chest trouble, but by the laryngoscope could be seen the left cord fixed nearly in the median line. The opinion that there was pressure upon the left recurrent nerve was confirmed by the sphygmographic tracing of the left radial artery, which was characteristic of the lesion suspected. The tracing at the right wrist was normal. In a few months, the direct evidences of aneurism were easily found, and the affected cord receded to the "cardiac" position, showing that both adductor and abductor filaments of the recurrent nerve were pressed upon. The patient had since died of rupture of aneurism.

The second case resembled the first in the more important particulars, but, although yet alive, has undoubted evidence of aneurism.

The third case, but recently seen, was one in which the hoarseness and change in voice were due to paralysis of the abductors of the right cord. No intra-laryngeal cause could be found, and as over the region of the ascending aorta near the arteria innominata, a bruit could be heard and slight thrill felt, an aneurism at this point was diagnosed. In this case the sphygmograph showed abnormal tracing at each wrist, which aided in fixing the location.

It is not a rule that an aneurism of this part of the aorta should press upon the right recurrent nerve, unless of large size. The proof of aneurism, however, is almost complete, and there is nothing else as yet found to cause the laryngeal paralysis. The patient returned to his home in the South, and Dr. Porter has not been advised of any change in his condition.

In all of these cases the patients sought relief from the laryngeal condition, not knowing of the thoracic lesion, and, in the first two, there was nothing in the chest to indicate it. We know that aneurism may exist without appreciable bruit or impulse, but these symptoms as well as increased area of dullness, are generally present when there is lesion enough to produce pressure upon the laryngeal nerve, and, in this, these two were also exceptional.

In all, as is generally true, the abductor filaments were first affected, but in the first as the pressure became greater, the adductor filaments became also impaired, and the changes in voice and respiration consequent were very interesting.

In these instances the sphygmograph gave valuable aid. It may not always give evidence of existing lesion, but where certain deviations from the normal tracings are obtained we can certainly trust its corroborative testimony. The importance of a laryngoscopic examination is self-evident in cases like those reported.

Dr. Louis Elsberg then read a paper on

REFLEX PHENOMENA DUE TO NASAL DISEASE.

In the discussion which followed, Dr. Mackenzie emphasized the importance and insisted upon the great frequency of cough as a symptom of nasal disease. Clinical observation and experimental investigation had led him to the following conclusions:

1. That in the nose there exists a well-defined and sensitive area, whose stimulation, either through a local pathological process, or through an irritant introduced from without, is capable of producing an excitation which finds its expression in a reflex act or in a series of reflected phenomena.

2. That this area corresponds, in all probability, with that portion of the nasal membrane which covers the turbinated corpora cavernosa.

3. That reflex acts are produced by stimulation of this area, and are only exceptionally evoked when the irritant is applied to other portions of the nasal mucous membrane.

4. That all parts of this area are not equally susceptible to irritation, the most sensitive spots being, probably, represented by those portions of the membrane which cover the inferior half of the lower turbinated bone, and the erectile body on the septum immediately opposite.

5. That the susceptibility to irritation varies in

different individuals; in some the slightest touch is sufficient to produce the reflex act, whilst in others it can only be produced after long-continued irritation.

That the reflex tract is limited to the above area is rendered probable by the following clinical facts:

1. That where reflex cough exists, this is the area chiefly, if not solely, involved.

2. That the act may be induced by artificial irritation of the diseased structure.

3. That it may be dissipated by topical applications, or removal of, the diseased membrane.

4. That polypi give rise to reflex phenomena only when they arise from or infringe upon the sensitive area.

5. That in cases where foreign bodies, such as pins, become impacted in the above area, reflex cough will sometimes occur, which latter is not observed when they lodge in the non-sensitive part of the nose.

Dr. Seiler said that he had reported in the *Archives of Laryngology* two cases of reflex irritation due to nasal disease, and gave the history of a case of chorea due to hypertrophies which was cured by the removal of the hypertrophies. He also mentioned the existence of cases, which he believed to be neurotic, in which a sudden copious discharge from the nose, accompanied by sneezing, headache, and so forth, of a watery fluid, attacked the patient, and continued for some time, to disappear as suddenly as it had set in.

Dr. Clinton Wagner then read a paper on

SMELL, HYGIENICALLY AND MEDICO-LEGALLY CONSIDERED.

He discussed the physical nature of odors, and pointed out the fact that many of them owed their characters to odorous particles held in suspension, while others were purely gaseous. The smells of various diseases, and different individuals were considered, and the fact that the sense of smell was analogous to that of sight in many respects; it can be cultivated and rendered keen by exercise, can be dulled by fatigue or over-use, and can be suddenly destroyed by overpowering odors. Where the sense of smell is lost by public nuisances, damages may be obtained from the municipality. The existence of odors is one important indication of the existence of certain causes of disease, which should be removed and destroyed.

After which Dr. Harrison Allen, of Philadelphia, presented some remarks on

ASYMMETRY OF THE NASAL CHAMBERS WITHOUT SEPTAL DEVIATION.

The subject of asymmetry of the nasal chambers, he said, can be considered from two points of view, viz., from the changes in proportion due to deflection of the nasal septum; and second, from the standpoint of inequality of the chambers themselves in subjects in whom the nasal septum is straight. The group last mentioned will form the basis of the present communication.

As a result of observation of ten examples of crania, selected from the anatomical cabinets of Philadelphia, it may be concluded that a difference in the diameters of the posterior nares can be detected. In the living subject, the writer has reason to believe that the same asymmetry in the posterior nares can be discerned, and that, at

least in the persons of those reporting for the relief of catarrhal affections, the number exhibiting such asymmetry is much larger than would appear from the examination of crania. As the result of clinical study in this direction, extending over the last two years, he concludes that nasal obstruction may be limited to one side of the nasal chambers only; and that such tendency to obstruction may be due to the congenital narrowing of this passage, the nasal septum remaining without deflection.

It is not necessary at this time to attempt an elaborate description of this variety of conformation of the nasal chambers, with its clinical applications, but simply to call attention to a fact which appears to have escaped observation, or, at least, to have received so little attention in the minds of observers as not to enter into questions of diagnosis and prognosis of nasal disorders. It is quite evident that imperfect nasal respiration, due to the above-mentioned cause, cannot be relieved by any operation on the septum, as these operations are at present defined, and that no operation short of drilling away the entire inferior turbinated bone will be likely to afford relief.

It is interesting to remark that among the crania exhibiting the above peculiarities, the best-marked examples were found in the skulls of idiots, in whom marked asymmetry of the cerebral fossæ was also seen. It is not at all unlikely that the real solution of the subject of congenital asymmetry, without septal deflection, is to be found in the peculiarities of development of the cerebral hemispheres themselves; and that the study of this subject can not be separated from the general subject of bilaterality; that is, the general subject of right and left symmetry as controlled by the cerebral nervous system.

(To be continued.)

A Final Word on the New York Code Quarrel.

With this title, the *Louisville Med. News* of May 19 gives an editorial thrashing to those recalcitrant New Yorkers who are endeavoring to upset the old code, and thus valiantly defends the Flints.

"The Flints, Austin sr., and jr., seem to be singled out as the chief objects of attack by the malevolent malcontents, who seek to overthrow the code, and to assume the dictatorship of the medical profession of America. Austin Flint, jr., barring Dr. Gross and Dr. Austin Flint, sr., has done more than any living American to make our profession illustrious. A great man himself, and the son and grandson of great men, he needs no eulogy. The world knows and admires him. Austin Flint, sr., is not only America's, but, since Sir Thomas Watson's death, he is the world's most eminent physician. Blameless man and stainless gentleman, of peerless eminence in medicine, he should be elected, as we believe he will be, the next president of the American Medical Association. In making Dr. Flint its chief magistrate, the Association will honor itself more even than it will the recipient of the office, and at the same time will vindicate the honor and honesty of the profession by the election to its highest office of so prominent and faithful and steadfast a defender of its code.

"We are for Austin Flint and the old code. For Dr. Flint forever, and for the code so long as it is the creed of the American Medical Association."

British Medical Association.

The fifty-first annual meeting of the British Medical Association is to be held in Liverpool on July 31 next and the three following days. Dr. A. T. H. Waters is the President elect. An address in Surgery will be delivered by Reginald Harrison, F. R. C. S.; and an address in Pathology, by C. Creighton, M. D. The arrangements are as follows: On Tuesday, July 31, church service at the Pro-Cathedral, 10:30 a. m.; first general meeting, 3 p. m.; adjourned general meeting, 8:15 p. m. On Wednesday, August 1, second general meeting and address in Surgery, 11 a. m.; sectional meetings, 1:30 to 5 p. m.; soirée in the Arts Gallery by the President and local committee, 9 p. m. On Thursday, August 2, third general meeting and sectional meetings, 10 a. m.; sectional meetings, 2 to 5 p. m.; public dinner in the Philharmonic Hall, 6:30 p. m. On Friday, August 3d, fourth general meeting, address in Pathology, and sectional meetings, 10 a. m.; concluding general meeting, 2 p. m.; soirée by the Mayor of Liverpool at the Town Hall, 9 p. m. On Saturday, August 4, excursions to various places of interest will be held.

German Apothecaries.

Berlin, with a population of 1,122,385 in 1880, had but sixty-nine apothecary shops, or one to every 16,266 of the population. This does not, of course, include the drug stores, which are not kept by licensed apothecaries, while many drugs are also sold in grocery stores. In Germany, the number of apothecaries being limited by law, each receives a better support, and there is less competition than in this country.

In Leipzig there is one to 10,000 inhabitants; in Cologne, one to 7,964; in Hanover, one to 8,207; in Breslau, one to 12,423; in Stuttgart, one to 7,151; and in Königsberg, one to 9,438.

Census of Providence, R. I.

A census of Providence, taken in the month of January by men of experience and responsibility, shows a total population of 116,755, of whom 55,736 were males, and 61,019 were females. The gain in population since the United States census of 1880 is 11,898, or 11.34 per cent., an average of 4.53 per cent. annually.

One of the Numerous Nuisances of New York.

The health authorities have found that in laying the pipes for supplying the city with steam, gas has been liberated from the saturated ground, and that the composition of tar and other materials with which the pipes have been covered also gives out a sickening smell when heated.

A Mammoth Model of the Human Brain.

Dr. Schulgu, of Heidelberg, has constructed a model of the human brain of such dimensions (25 vol.) that every fibre or fasciculus can be traced from the spinal cord to the cortex, or some of the ganglia of brain.

Items.

—Mr. Arthur Benson reports a case of retinitis albuminaria, without constitutional disturbance.

—Among the million of paupers aided by the public charities of England in 1865 there were eight hundred thousand drunkards.

—St. Louis is supplied with water gas for fuel purposes, made by the Lowe process. The laying of the pipes is progressing, with ten miles under contract.

The *Chemist and Druggist*, April 14, 1883, says that the taste and smell of turpentine are best masked by sulphuric ether. A mixture of turpentine $\frac{3}{4}$ i., ether $\frac{3}{4}$ j., syrup of orange $\frac{3}{4}$ j., and water $\frac{3}{4}$ iv., can be taken in teaspoonful doses quite readily.

—The *Cincinnati Lancet* says that "the business of looking after the health of that city is vested in a health board whose active members are two saloon-keepers, two druggists, and one politician."

—The report of the Vaccination Bureau of New York city shows that in the year 1882 the physicians of the Board of Health performed 99,661 vaccinations. In the last seven years nearly 500,000 persons have been vaccinated by members of the bureau.

—The forms of pessaries figured in recent works on gynecology are as varied as the inventive genius of man can make them. Some resemble a grasshopper, some the devil-fish, some the horse-shoe, some the side-saddle, and others are but plain rings.

—A glue ready for use is made by adding to any quantity of glue common whiskey instead of water. Put both together in a bottle, cork it tight, set aside for a few days, and it is ready for use. In cold weather it may have to be placed in hot water for a few minutes before it gets soft.

MARRIAGES.

BOYER—WOLFF.—Tuesday, April 24, 1883, by Rev. G. W. Dubois, Walter N. Boyer, M. D., and Miss Laura V. Wolff, at the residence of Mr. and Mrs. Charles H. Wolff, the bride's parents, in Mt. Washington, O.

HIGGINS—OAT.—In Philadelphia, by Rev. S. S. Belville, of the N. J. Conference, M. E., Dr. F. C. Higgins, of Defiance, Ohio, and Miss Emma Belville Oat, of Philadelphia, Pa.

TAGGART—GRANT.—In Shenandoah, Pa., April 30, by Rev. F. F. Kolb, Dr. David Taggart, of Frackville, Pa., and Mary Grant, of Shenandoah.

TINKER—SANGER.—On Tuesday, May 15, at the residence of Horace B. Clafin, Brooklyn, by the Rev. Thomas B. McLeod, Horace H. Tinker, M. D., and Anna P. Sanger.

DEATHS.

BRADFORD.—In New York, suddenly, May 10, at his late residence, No. 15 West 48th street, Theodore Dwight Bradford, M. D., in the 45th year of his age.

BUCKNER.—At Shelbyville, Ky., Friday, May 4, 1883, Rev. Dr. Edmund P. Buckner, aged 61 years.

LATIMER.—In New York, on Tuesday, May 15, Jennie B., wife of Dr. C. E. Latimer, aged 46 years.

PAULDING.—May 1, 1883, in the 30th year of his age, at Fort Sidney, Neb., Captain Holmes Offley Paulding, Assistant Surgeon U. S. Army, only son of the late Commander Leonard Paulding, U. S. Navy.

PHISTER.—In this city, on the 18th of May, Benjamin Phister, M. D.

STOKES.—In this city, on May 12, of Bright's disease, Dr. Chas. Stokes, son of H. M. and the late Dr. T. J. P. Stokes, in the thirty-eighth year of his age.

JENSEN'S CRYSTAL PEPSIN,

Strictly Inodorous and Tasteless, and Perfectly Soluble in Water without Acid.

(gr. j. of it will dissolve the boiled whites of two or three eggs.)

See advertisement on page 10.

LECTURE.

ON THE TREATMENT OF TYPHOID FEVER.*

BY PROFESSOR GERMAIN SÉE,
Paris, France.

(Continued from page 480.)

The third method is that which consists in the use of antithermic and antipyretic remedies. There is a clear distinction between these terms, the action of the first being much more limited than the action of the second; practically, however, we may consider them together. In that class, then, we may reckon such antiseptics as salicylic acid and salicylate of soda, which are powerful antithermic remedies. To this class, also, belong cold baths, quinine and alcohol. Quinine is the type of antipyretics, having a marked action on the temperature, the heart, the pulse, the blood-vessels, in short, all the constituent elements of the fever.

What is the *raison d'être*, or justification of the antipyretic treatment?

While the followers of Hippocrates, Galen and Stahl regarded fever as a curative effort of nature—a means of depuration of vitiated humors—in our own time we have seen Donis and Bouillaud declare fever to be baneful, the source of grave lesions. Bartels, Jurgensen, Liebermeister, Hagenbach, have all demonstrated the pernicious influence of excessive heat on the organism.

We have, in fact, learned to regard the therapeutics of fever as a warfare against a master-symptom which dominates the entire morbid scene, and which alone deserves serious consider-

ation. I allude, of course, to continued, as distinguished from ephemeral fevers.

What are some of the evil effects of fever on the animal economy?

I will briefly mention the principal of them. They are:

1. Wasting of the tissues. This wasting is a veritable consumption, and finds expression in an excessive elimination of urea, over-production of carbonic acid, and disappearance of fat. As for the excretion of urea, it is seventy per cent. greater than in health. The quantity of carbonic acid formed and eliminated, is fully twice the average of health. The consumption of fat is proved by the emaciation of the fever patient.

2. Fatty degeneration of organs. This has been again and again noted in the liver, the kidneys, and the muscles. Experimentation with animals has proved the accuracy of the inferences of the human autopsy. Hares, dogs and other animals have been subjected to gradually increasing high temperatures; degenerations of the muscles, heart, kidney, and liver have resulted.

3. Something more about the effects of prolonged febrile heat on the heart and circulation needs to be said. While fatty degenerations are very frequent, and often cause death, the heart may, without being anatomically injured, suffer such depression that the circulation may become virtually nil. The extremities are cyanosed, stases occur in the lungs and dependent parts, and thromboses form in the vessels.

4. The nervous system does not escape lesions, which may take on the form of inflammatory or degenerative disease; cerebral oedema has been noted.

*Translated by E. P. Hurd, M. D., Newburyport, Mass.

Antithermic Treatment by Cold Baths.

Refrigeration by the outward application of cold has been a favorite method of treating fevers. It has been believed that it is as easy to cool a fever patient as to cool a piece of metal. The physiological fact has been ignored that in the case of the fever patient, the organism is provided with a means of regulation and production of heat. Place an animal or a human being in cold water, and a double action ensues. There is first a contraction of the small superficial vessels, which slows the peripheral circulation, drives the blood towards the centre, and thus diminishes notably the chances of refrigeration of the entire organism. There is first an excitation (of a kind not well understood), of the calorific centre, which causes an increased production of heat, and this not only during the bath, but for some time after. So then, during the bath, nothing great is gained, and after the bath there is augmentation of temperature. No satisfactory refrigeration is obtained unless the patient is kept in the bath some time, say twenty minutes or half an hour.

You may, if you like, cool down the water to 10 or 12 degrees C. (very near the freezing point) as Liebermeister recommends, and you will, without doubt, refrigerate your patient, but animal heat may never return.

The cold bath produces another effect, and an effect which I do not hesitate to call disastrous; it exaggerates the oxidations which take place in the recesses of the tissues, causing more oxygen to be absorbed, and more urea and carbonic acid to be excreted; the tissues, the fat and the albuminates disappear more rapidly in consequence. All physiologists in France and Germany agree on this point.

The excretion of carbonic acid which ordinarily is about 13 grams in half an hour, is increased by a bath of 32 degrees to 15 grams, and when the water is the temperature of 18 degrees, it is 39 grams. The excretion of urea augments in the same proportions. But this is not all. Cold baths, besides their physiological inconveniences, have clinical disadvantages in the way of grave complications which they are likely to determine. Pneumonia (not hypostatic congestion of the lungs, but frank pneumonia), has again and again resulted from the use of the cold bath, according to the method of Brand. Statistics recently published by a physician of Lyons bear me out in this statement (*i. e.*, ten (10) pneumonias out of sixty-three (63) typhoid patients). Another complication no less severe is intestinal hemorrhage. During the period when this method was in use

among us, I had experience of such hemorrhage in every fourth or fifth case. It does not stand to reason that the sudden forcing of a great mass of blood from the periphery to the internal organs, as a result of the contraction of the peripheral vessels, can have no disastrous effect on a congested ulcerated intestine!

What effect, moreover, is this intropulsion of blood likely to have on a weakened heart, whose fibres are undergoing degeneration?

The cold bath treatment, then, cannot be defended from either a physiological or clinical standpoint. I do not, however, condemn douches and cold lotions, which in some cases may have a good effect, especially in preventing cerebro-spinal complications.

Treatment of Typhoid Fever by Quinine.

Sulphate of quinine, tried as far back as 1840, by Broqua and Louis, but without much success, then by Rillet and Barthez, then by Pereyra and Boucher a few years later (1846), passed out of use as a febrifuge agent, till, in 1859, Vogt, in Switzerland, applied it to the treatment of fevers in general and of typhoid fever in particular. Shortly after, Liebermeister, following the course marked out by Vogt, instituted in a regular manner the treatment whose rules I shall now lay down, after having indicated the valuable properties of this medicament.

Properties of Sulphate of Quinine.

Quinine is an antithermic remedy. It diminishes oxidations in the blood and in the tissues. It is a precious cardio-vascular medicament. It has also been considered an anti-zymotic. Although Binz has defined the anti-zymotic properties of quinine, allying it to the salicylic series; although it arrests fermentations and putrefactions; although it acts in a special manner on the micro-organisms of marsh-fevers, we are not obliged to take into account its antiseptic power in the treatment of typhoid fever; for the most that we can do in this direction is, possibly, to utilize this singular action of quinine on the amoeboid movements of certain cells, and especially the leucocytes. It has been claimed that by "quininizing" a tissue we may stay the transudation or diapedesis of the leucocytes, and thus favorably modify inflammation. Is there any possible application of this kind to the secondary inflammations so frequent in dothrinenteritis? This question cannot be answered affirmatively. It would be necessary to give two to three kilograms of quinine to effect this object.

Quinine is also said to act on the whole cerebro-spinal system, diminishing reflex action and aug-

menting tone. Is it for this reason that it has been vaunted in typhoid fever of ataxic form? What is certain is that if the cerebro-spinal disturbances are almost constant under the influence of febrile excess, they ought necessarily to undergo marked abatement from the refrigeration produced by quinine.

Rules for the Administration of Quinine.

(1) *Quality of the Drug.*—The first condition for the obtention of a good result is to have a pure article for experimentation. M. Laborde has recently called attention to the adulterations practised with the quinine of commerce; in one sample he found 43 per cent. of cinchonine. Other sophistications are common. You ought then to be sure that your quinine is pure.

(2) *Dose.*—The dose of quinine for refrigeration in typhoid fever is larger than the dose indicated in fever and ague, the medium dose for an adult being from two grammes to two grammes and a half. [Somewhat more than thirty grains.] If you are not prepared to exceed one gramme (fifteen grains) *per diem*, you had better refrain from the use of the remedy. An “anti-periodic” of half a scruple to a scruple has not the least effect on the typhoid temperature. This is why Broqua and the followers of St. Antoini and Briquet prescribed doses of three, four, and five grammes (forty-five to seventy-five grains) a day, thus dangerously exaggerating the effects of the medicament, and bringing discredit on the treatment.

Mode of Administration.—The quinine may be given in powder, in capsules, in acid solution, which is with difficulty taken, in pills, to be possibly passed in the stools without undergoing solution, or better still, in powder stirred into coffee, which enables it to be well borne by the stomach.

Enemas with quinine, pommades, and hypodermic injections, are not to be thought of in this connection.

Interval Between Doses.—My method consists in giving one dose of a gram (15 grains) early in the morning, and a second dose of a gram about 9 o'clock in the evening. It is perfectly safe to give this quantity of quinine daily to an adult patient. If you make ten doses of the two grams instead of two doses, you will not obtain the antipyretic effect which you desire; the quinine will be rapidly eliminated by the urine before there will be enough in the blood at any one time to produce an effect. Lieberman advises to give the first gram dose at three o'clock in the afternoon, and the second dose about two hours later.

Physiological Effects.—The quinine commences

rapidly to act on the brain; whose disturbances manifest themselves by buzzings in the ears, tremblings of the limbs, troubles of equilibration, weakness, and intoxication. Its febrifuge action is realized after six or eight hours, and attains its maximum after eight to twelve hours. After this period, and often after a free sudation, the fever heat reappears, but without attaining by the second day the height of the previous day. We find generally that we have gained a degree and a half. Only in the most desperate cases is there absence of the thermal fall.

In general, it takes from twenty-five to thirty-six hours for the quinine to be eliminated, when the effect ceases. The elimination by the urine is, however, often intermittent, ceasing at one time to reappear after a few hours. In this respect the elimination of quinine resembles that of arsenic and mercury.

In my method of administration, I anticipated the evening rise of fever by giving the first full dose in the morning, and the evening dose prolongs and intensifies the effect of the morning dose.

It has been said that individuals of strong constitutions require a larger dose than weakly individuals; this is a mistake. Children from three to five years old may take one gram daily; from six to ten years, one and a half grams; from eleven to fifteen years, one and a half grams up to two grams. Such doses have often been prescribed by Barthez.

The treatment, when commenced, ought to be continued, the quinine being given daily, in the same, or in a lessened dose. If you suspend the treatment, you lose what you have gained.

Some refractory cases resist the largest doses that we dare to give. I have seen patients whose fever remained at its customary height after a dose of forty-five grains (three grams). I never have exceeded this dose. These are the grave cases that resist all treatment. The vitality of the organs and tissues is too far gone for them to respond to any medicament. In tetanus and in cholera you often see the same tolerance of the most powerful drugs. You must not abandon such cases, for you do not know beforehand whether there will be reaction or not. There are great fires which water cannot extinguish, but this is no excuse for abandoning water and the pumps.

The Antithermic Action of Quinine.

It produces but slight modifications in a person in health. Lieberman has seen inconspicuous effects with a dose of two grammes. Small doses produce a very trifling lowering of the tempera-

ture; according to Sidney Ringer, not more than one or two-tenths of a degree. In febrile states, the fall of temperature is marked after full doses, as before stated.

Causes of the Refrigeration of the Quinine.—It can only be explained on the assumption of a retardation and lowering of thermogenesis. If you cut the spinal cord in an animal, there is ordinarily produced an excess of heat, *post mortem*, due to chemical processes which persist after death. If you "quininize" the animal, the temperature does not rise. This effect seems like an inhibition of chemical processes by the quinine. Quinine actually diminishes the oxidations of the economy. Ranke and Kerner have proved that there is diminution of urea from 24 to 30 per cent. The elimination of carbonic acid is also lessened, as proved by Strasburg and Buss.

Quinine as a Cardio-vascular Medicament.—This is undoubtedly the most remarkable of the properties of quinine. Fever determines a diminution, more or less considerable, of the intra-cardiac and vascular tension, which finds expression in the dicrotic pulse. This dicrotism is always proportional to the elevation of body temperature. Sulphate of quinine, in the dose of two grammes a day, brings back toward the normal the cardio-vascular tension, as the sphygmographic and radio-graphic traces testify. The energy of the contractions of the heart is augmented. All experiments and observations made with animals and with man, sick or well, have given exactly the same results, that is, have set forth in bold relief the marvellous property which quinine possesses of staying the diminution of pressure produced by elevation of temperature, and of augmenting the tension of blood in the heart and vessels. It prevents that relaxation of the blood vessels which forms the point of departure of dicrotism.

With sulphate of quinine we are not compelled to fear, as when cold baths are administered, collapse of the heart, respiratory anguish, and intestinal hemorrhages, and we may continue the treatment eight and even fifteen days with perfect safety.

Alcohol in Typhoid Fever.

Alcohol acts in a similar manner to quinine, and may be given concurrently with the latter through the entire duration of the malady. Far from being a calorific agent, as has been pretended, increasing thermogenesis, it becomes a valuable means of restraining waste, for it moderates the organic combustions, and lessens denutrition. Like quinine, it reduces the temperature

of the body, as all experiments on men and animals, sick or well, demonstrate. It is then, like quinine, a sub-oxidizing medicament; it diminishes the proportion of carbonic acid exhaled, and of urea excreted; it economizes substances introduced into the organism; it lessens disassimilation. It moreover supports the strength, stimulates the nervous functions, and is, from every point of view, the congener and rival of quinine. It is, however, of most signal use when administered along with quinine, which maintains especially the contractile energy of the heart. The doses of alcohol ought to be considerably larger than those ordinarily given, if one would obtain a refrigerant effect; but as it is impossible to exceed a certain dose without injury, it is well always to aid its action by suitable doses of quinine. This mixed treatment, in my judgment, constitutes the very best means of preservation of the vital forces during this protracted tedious disease.

The following table gives a bird's-eye view of the principal phenomena of the febrile processes, as habitually witnessed; the right-hand table gives the same processes as modified by quinine:

Febrile Phenomena Without Quinine.

(1) The combustions are exaggerated. CO₂ is increased.

(2) Urea, which indicates the combustion of the tissues and albuminous matter, is greatly increased.

(3) The pulse is accelerated.

(4) It is dicrotic.

(5) The temperature is from 38 to 41° C.

(6) The heart becomes gradually enfeebled.

The same Phenomena with Quinine.

(1) The combustions are diminished. The formation and elimination of CO₂ is lessened.

(2) Urea is lessened 15 to 24 per cent.

(3) The pulse is slowed.

(4) The dicrotism almost always disappears.

(5) The temperature falls a degree and a half.

(6) The heart acquires more contractile force.

COMMUNICATIONS.

VIEWS OF MORTALITY STATISTICS, WITH SPECIAL REFERENCE TO THE U. S. CENSUS RETURNS OF 1880.

BY THOS. S. SOZINSKEY, M. D., PH. D.,
Of Philadelphia.

In the January issue of *The American Journal of the Medical Sciences* there is a very instructive article on the registration of vital statistics, by Dr. John S. Billings, of the United States Army, to whom, I need hardly say, the profession is under considerable obligations for much useful work. In

it the importance of accuracy and completeness in such statistics is insisted on, and the means by which these desirable features of them may be at least approximately attained, are treated of interestingly and fully. A few words of advice, I may say, are also given to presumptuous critics, a class who, he would seem to think with Bacon, not infrequently assume that "that which they understand not is false set down." On the points treated of by the learned doctor it is not my purpose on this occasion to dwell; my purpose is to treat of the interpretation, so to speak, of mortality statistics—a still more difficult subject, and one that is but poorly understood by many. I do not intend to take up all the phases of this important theme. To discuss the matter in its entirety and at length would require much space. I have elsewhere* treated of it somewhat comprehensively.

Notwithstanding what Dr. Billings says about critics—a class, after all, whose better members, at least, do something in the interest of truth and progress—my remarks will be in the main critical. In fact, it is hardly possible to discuss the subject satisfactorily, or at least interestingly, in any other way, there being much risk of becoming wearisome and unpleasantly didactic. I will dwell principally on errors which should be avoided in handling statistics. And I will not take a newspaper article, or any other every-day production, as the basis of what I shall say—it would not be worth while to do so; I will go where one should expect soundness; I will take Dr. Billings' introduction to the abstract of the mortality statistics of the United States for the census year ending June 1, 1880, given in "The Compendium of the Census," which has just been issued.

According to the census returns for the year ending June 1, 1860, the death-rate was 12.5 per 1,000 of the population; in the year ending June 1, 1870, it was 12.8 per 1,000; and in the year ending June 1, 1880, it was 15.1 per 1,000. Referring to these figures for the year 1880, Dr. Billings says, "This does not indicate any actual increase in the number of deaths as compared with the living population." If the doctor had been duly on guard against indulging in unsound logic, he would have introduced the saving word *necessarily* before *indicate*. Indeed it may be set down as an important truth that one who has little love for qualifying words and phrases had better avoid speaking or writing

about any of the philosophical aspects of vital statistics. As Dr. Parkes says, "properly grouping complex facts so as to analyze them and to bring out all the possible inferences, can only be done by the most subtle and *logical* minds." However, Dr. Billings continues: "It shows rather that the efforts made in the census of 1880, to obtain more complete returns of deaths than had been collected in previous enumerations, have been to some extent successful." On the doctor's account and for other reasons, I would gladly take this statement to be true; but unfortunately I can find only a very little more ground than the doctor gives for believing it, which is none at all. He needs to be reminded that coincidence is one thing, and cause and effect another. The *non causa pro causa* or *post hoc ergo propter hoc* fallacy is far too common—especially in the writings of doctors, disgustingly common. My patient took such and such a medicine among others, perhaps with them, and got well; therefore it cured him. Very likely nature did it, and possibly in spite of that particular medicine.

I am aware, however, that some special pains were taken to make the returns of deaths reasonably complete in the census of 1880, but I have excellent reasons for believing that they were largely in vain. There is one obvious reason why the statistics for 1880 should be fuller than in other census years, all other things being equal; namely, because the local returns for the States of Massachusetts and New Jersey and the District of Columbia and twenty-two cities, were taken in place of a canvass by the census enumerators, returns which, being based on "a regular system of registration and on burial permits, are therefore probably very nearly accurate." In the State of Massachusetts, excepting Boston, the enumerators' returns were deficient 26.42 per cent. of the number returned by them; and in New Jersey they were deficient 34.45 per cent. Culling off a third in these States and cities would reduce the rate for the whole country considerably. This much may fairly be said, that while pot-house politicians compose the body of the enumerators there will be little room to hope that the returns will be very satisfactory.

As hinted already, I believe that Dr. Billings is in error, at least largely, in referring the increased death-rate in 1880 to greater completeness in the returns. I think that the increase can be shown to be, to a great extent, at least, the result of a heavier mortality in 1880 than in 1870, or 1860.

Now, if Dr. Billings had taken a critical glance at the causes of the deaths in 1880 he would

*"Aspects of Mortality Statistics," *Penn Monthly*, April, 1881.

likely have hesitated before making the assertions given above. Looking at death or any other vital statistics in their entirety is not apt to give right impressions. The doctor practically assumes that the deaths were in all respects essentially the same in proportion to the population in the census years 1860, 1870 and 1880. There is no sound reason for doing this; no reason at all in fact; whereas there are reasons sufficient and to spare for holding a reverse opinion. No disease is constantly alike in its fatality from year to year. Some, however, are comparatively so, while others are markedly otherwise. The various zymotic diseases are of the latter class. An epidemic disease may be infinitely more destructive one year than another. Weather differences are in themselves ample to cause very decided differences in the extent and character of the mortality from year to year—these being, as every one knows, great enough with us.

The deaths from many individual diseases and different classes of diseases were very far from similar in the census years 1870 and 1880. I have prepared the following table, which will show this very clearly:

DISEASES.	1870.		1880.	
	PROP. OF DEATHS- <i>To the Whole.</i>	<i>To the Pop...</i>	PROP. OF DEATHS- <i>To the Whole.</i>	<i>To the Pop...</i>
Measles	1 to 53	1 to 4,189	1 to 86	1 to 5,717
Scarlet Fever.....	1 to 24	1 to 1,904	1 to 46	1 to 3,055
Enteric Fever.....	1 to 22	1 to 1,744	1 to 33	1 to 2,189
Diphtheria.....	1 to 75	1 to 6,139	1 to 20	1 to 1,306
Whooping-Cough....	1 to 54	1 to 4,296	1 to 67	1 to 4,477
Malarial Fevers.....	1 to 42	1 to 3,312	1 to 37	1 to 2,475
Consumption	1 to 7	1 to 552	1 to 8	1 to 546
Respiratory Diseases.	1 to 7.6	1 to 605	1 to 7	1 to 565
Nervous Diseases....	1 to 8	1 to 640	1 to 9	1 to 599
Digestive Diseases....	1 to 6.6	1 to 523	1 to 7.6	1 to 503
Diarrheal Diseases...	1 to 11	1 to 914	1 to 11	1 to 765

As the reader will observe, there was an increase in the death-rate in 1880 from diphtheria and malarial, diarrheal, respiratory and nervous diseases and more or less of a decrease from measles, scarlet fever, whooping-cough, and enteric fever. The increase from diphtheria was shockingly great: in 1880 there were 38,398 deaths reported, while in 1870 there were only 6,303. If the deaths from this disease had been as few in 1880 as in 1870, the whole death-rate in the former would have been 14.4 instead of 15.1. Another contagious disease which tended to increase the mortality in 1880 was yellow fever. The deaths reported from this disease in 1870 were only 177, while in 1880 there were probably 1000

or more*. There were 587 in Memphis alone. The increase in deaths from malarial fevers was large. Likely it was real. The table of temperatures given below would prepare one for many cases of these diseases. A cool September and a warm October and mild winter as a whole, with great ranges of temperature, will almost inevitably produce many cases. In the census year ending June 1, 1880, there were forty deaths from malarial fevers, which was a fifth more than in preceding years, in Philadelphia.

Of the diseases which are nearly alike destructive from year to year, consumption is a notable one. Thus, in Philadelphia for the three years ending with 1881, the deaths from this disease were respectively 2,471, 2,692, and 2,768. The increase here is about proportionate with the increase in the population. In that city the deaths from the disease were 1 to 308 of the population in 1870, and 1 to 325 in 1880. Now, if the returns of the deaths from consumption should be in nearly similar proportion to the population from year to year, of course, the returns of it should give a fair idea of the completeness of the returns as a whole. This test would not give much support to Dr. Billings in his assertion that the returns for the census year 1880 are more complete than those for that of 1870. As seen above, there was 1 death to every 552 of the population in 1870, while in 1880 there was 1 to every 546.

The fact that the proportion of deaths reported from consumption in 1880 was 1 to 8, while in 1870 it was 1 to 7, would apparently indicate that the returns of deaths from other diseases were fuller in the former than in the latter year, the proportion of deaths from it to the population being taken as alike each year. What has been said above, however, regarding the greater mortality in 1880, from diphtheria and other diseases, greatly lessens the probability of the truth of this.

Probably, as Dr. Billings says, the deficiency in returns of deaths "is greatest in the case of infants, of females and of foreigners, and increases in a tolerably uniform ratio for each month, going backward in time from the date of taking the census. It is also greatest in the more thinly settled sections of the country." Taking the greatest deficiency to be in the case of young children, it of course follows, other things being equal, that the more complete the returns the greater is the proportion of such children. Now,

*The returns given in the *Compendium* do not indicate the number.

in 1870 the proportion of deaths of persons under one year to the whole was 1 to 4.4; and in 1880 it was 1 to 4.3. The proportion of deaths of persons under five years in 1870 was 1 to 2.4, and in 1880 it was 1 to 2.5. There is but little in these figures to support Dr. Billings. The slight increase in the proportion of deaths of infants in 1880 may not be entirely, or at all, due to greater completeness in the returns. The increased deaths from diphtheria, diarrhoeal diseases, etc., would, perhaps, entirely account for it.

As stated above, weather differences are in themselves ample to cause decided differences in the extent and character of the mortality from year to year. Now, it is not possible to furnish, in a limited space, definite information about the weather throughout the United States for any particular year, the extent of territory being so great. And indeed it is difficult to get definite meteorological information for any year previous to 1872, the U. S. Signal Service Bureau not being fully in operation till then. The following table, compiled from the observations so long and admirably made at the Pennsylvania Hospital, indicates in degrees Fahrenheit the state of temperature at Philadelphia, for the census year ending June 1, 1870 and the one ending June 1, 1880:

MONTH.	1869-70.		1879-80.	
	MEAN.	RANGE.	MEAN.	RANGE.
June	73.62	38.0	73.18	48.0
July	76.54	35.5	77.32	40.0
August	76.30	37.5	74.53	40.0
September	67.33	40.0	64.70	46.0
October	52.50	44.5	62.09	56.0
November	41.27	32.0	42.96	54.0
December	37.31	42.5	37.81	50.5
January	41.07	51.5	39.12	39.0
February	34.73	48.0	39.03	55.5
March	37.87	38.0	39.64	56.5
April	53.50	49.0	53.10	55.5
May	65.26	34.5	70.59	64.5

These figures will give some idea of the temperature in a large section of the United States in the two census years. It is not to be presumed that they will give a very definite idea. However, it will be seen by them that July was warmer and October, February, March and May greatly warmer, in the census year ending June 1, 1880, than the corresponding months of the census year ending June 1, 1870; but what is more remarkable is the greater range of temperature every month, except January, during the former than the latter year. The figures of ranges in the former year are very extraordinary. It may be said that the winter of 1879-80 was altogether mild, but with great ranges of temperature. In a volume before me (the Ninth Annual Report of the State Board of Health of Michigan) an

intelligent meteorologist (Dr. Baker) says: "The winter (1879-80) which is now far spent seems destined to take a memorable place in the annals of meteorology. Although its extraordinary thermometric ranges have yet to be fully made up, it bids fair to exhibit the most marked record of sunshine and warmth east of the Mississippi and south of the forty-fifth parallel." Now, generally speaking, it is the extent of range of temperature which tells on health. The records show a very heavy mortality in Philadelphia in July, September and October, 1879, and in January, April and May, 1880. In August, 1879, the mortality was somewhat less than in August, 1869, and the same was the case in December and in February, 1880. From all the data at hand I should say that the census year ending June 1, 1880, was much less healthful than that ending June 1, 1870.

There are reasons besides the state of the weather why an increased mortality might have been expected in 1880 over what it was in 1870. Among them are these two, namely, the fact that the deaths of great numbers of young men in the civil war lessened greatly the number who, in 1870, would otherwise have been parents and passing beyond middle life; and the other, that the great multitudes of immigrants who landed on our shores from the close of the civil war forward had largely become parents, and were fast passing beyond vigorous adult life in 1880.

(To be continued).

THE ARSENITE OF BROMINE AND ITS USE IN THE TREATMENT OF DIABETES MELLITUS.

BY R. H. GILLIFORD, M. D.,
Of Allegheny, Pa.

Read before a meeting of the Allegheny County Medical Society at Pittsburgh, Pa., May 15, 1883.

In the early part of December, 1882, I began some experiments with bromine and arsenious acid, the results of which have in part been corroborated by experiments performed at my request by a practical chemist. As I can find no account in any works on chemistry of a compound or salt formed by the union of bromine and arsenious acid, I submit my results or views with diffidence, and will welcome either correction or confirmation. I find that bromine and arsenious acid will unite under certain favoring conditions, in the proportions of two hundred and forty parts by weight of bromine to ninety-nine parts by weight of arsenious acid. When they are perfectly

united, or the arsenious acid completely dissolved by the bromine, they form an oily liquid, soluble in water and alcohol without any apparent reaction. They unite very slowly, and sometimes seem for many days as if no union was taking place, when merely agitated in contact with each other. When united without the addition of water, they form a salt which consists of three equivalents of bromine and one equivalent of arsenious acid, and would be represented by $\text{AsO}_3, 3 \text{ Br}$.

When water is added before the bromine is united completely with the arsenious acid, or when bromine and arsenious acid are brought together in the presence of water, there takes place an immediate and rapid reaction, with the evolution of considerable heat. Evidently the water is decomposed, and hydrobromic and arsenic acids are formed, and the result is a solution of the two acids with a little free bromine in the excess of water.

The solution used in the appended cases was made by the complete union of the arsenious acid and bromine before the addition of water, and from observation I believe it to be much less irritating to the stomach than a solution of the hydrobromic and arsenic acids.

As I have seen no account of any compound of bromine and arsenious acid in any medical works or journals, I have concluded that I have been the first, in this country at least, to make and prescribe arsenite of bromine.

Dr. Theodore Clemens, of Frankfort, Germany, has been using some compound of bromine and arsenic in the treatment of diabetes, and has reported great benefit from its use.

The medical journals have called his remedy bromide of arsenic, but from the known properties of bromide of arsenic, it seems much more probable that the article he uses is either arsenite of bromine, or a solution of the hydrobromic and arsenic acids.

I have made a solution of arsenite of bromine and used it in a number of cases, and furnished it to several physicians, who have prescribed it and reported to me its effects in the treatment of diabetes mellitus.

While the notes of some cases are incomplete in many important points, yet its use has been followed by the most marked benefit in every case of diabetes in which it has been prescribed so far.

Some of the cases seem to have made a complete recovery, others seem to be progressing steadily towards a complete recovery. Dr. C. Emmerling, of Penn avenue, Pittsburgh, has

treated two cases of diabetes mellitus with my solution.

The first case, a male, aged 30 years, was benefited so much that in two weeks' treatment he had got rid of all the distressing symptoms of the disease; the specific gravity of the urine falling from 1036 to 1029, and the quantity of urine being decreased to less than one-half that passed at the beginning of the use of the remedy.

The patient being of dissipated habits, disappeared from the doctor's observation.

Dr. Emmerling's other patient met with the same marked and immediate improvement following the use of the remedy. His age was 47 years, a saloon-keeper by occupation, and a very large man, and a very heavy eater and drinker; the quantity of urine passed was enormous. Dr. Emmerling reports that he seems to be getting well. The specific gravity of the urine has been reduced from 1036 to 1028, and the quantity of urine passed has been reduced to four and one half pints in twenty-four hours after one month's treatment.

Dr. A. D. Johnston, of Sedgwick street, Allegheny, furnishes the following notes of a case treated by him: Weston Hall, aged 19 years, laborer in steel works; called March 19, 1883, for treatment, and stated as follows: About January 1, 1883, he was carrying one end of a steel axle, and the man at the other end allowed his end to fall: the jar or shock was so severe as to unfit him for work for several days. Shortly after the accident he noticed an increase in the flow of his urine. The flow increased until March 20; he was passing three gallons of urine in twenty-four hours, of acid reaction and specific gravity of 1035.

His thirst was constant. He cannot eat enough to satisfy the cravings of hunger, and is very much emaciated and very weak. Tests for grape-sugar in the urine show not less than twenty-five grains of sugar to the fluid ounce, estimated by the fermentation test.

March 22d. A solution of arsenite of bromine was procured from Dr. Gilliford, and two drops ordered to be taken four times daily.

March 25th. Improvement marked as regards the quantity of urine passed; thirst not nearly so excessive; feels better after eating; feels stronger; spasms of the calves of the legs disappearing; specific gravity of the urine 1030; can lie until nearly morning, whereas formerly he was compelled to rise at least three times during the night to void urine. Dose increased to four drops four times a day.

March 29th. The patient is able to lie all night

without rising to urinate. The improvement in strength and general health very marked.

April 17th. The patient thinks himself well. His gain in flesh is very noticeable. Urine passed in twenty-four hours, eighty fluid ounces, specific gravity 1020, acid reaction. Fehling's test shows no sugar in the urine. The patient leaves for Clarion county in a few days to go to work, promising to write weekly and keep a record of the amount of urine passed.

Dr. J. B. Johnston, of No. 25 Pennsylvania avenue, Allegheny, furnishes the following notes:

On the 16th day of April, 1883, I was called to see a boy aged sixteen years and five months. I found him very much emaciated, but complaining of nothing in particular, only that his thirst was insatiable, and he was *ravenously* hungry, as he said. He said his fauces and throat were very dry and parched. I examined his *tongue* and found it red and fissured. From the symptoms, I concluded he had diabetes; he was passing from a gallon to a gallon and one half in twenty-four hours of limpid urine. I immediately made the tests for saccharine urine, and found it to contain sugar in a very decided quantity, *Moore's, Tromer's*, and the *yeast* test all verifying each other. I put him on the usual treatment of cutting off the supplies, and fed him mostly upon meats, animal broths, vegetable soups, fresh fish, etc., including cabbage and turnips. The sp. gr. when I first saw him was 1038. I found it to vary in density from 1035 to 1040. I tried the different modes of treatment usually resorted to, but must say I found little or no improvement in the case. I found the best results in the first part of the treatment from tinct. ferri. mur., given in fifteen-drop doses half an hour after meals, in a wine-glassful of water. During the time he was taking the *iron*, the thirst was not so distressing nor was the appetite so voracious, but the urine was nearly if not quite as copious, and the specific gravity remained high.

During the time the iron was being given, there was passed on

April 27, 132 fluid ounces of urine.

" 28, 130 " " "

" 29, 129 " " "

" 30, 127 " " "

May 1, 131 " " "

" 2, 129 " " "

" 3, 126 " " "

During this time the sp. gr. varied a little, from 1036 to 1038. On the 4th day of May I began giving four drops of solution of *arsenite* of *bromine* (my attention having been called to it by

Dr. R. H. Gilliford), largely diluted with water, half an hour after each meal. On the 5th the quantity of urine to my surprise had fallen to 110½ fl. oz.—on the 6th to 100 fl. oz. with sp. gr. of 1034.

On the 7th I again examined the density of the urine, and found it 1032, with a still decreased quantity, 98 fl. oz.

May 8th I did not take the sp. gr. but found 94 ounces of urine. Patient is sleeping well at night, and says he does not need to get up so often to urinate.

May 9th. Specific gravity 1032, and 94 ounces of urine. Same as on 8th, but he confessed to indiscretions in his diet.

10th. Specific gravity 1031, with 92 ounces of urine. Thinking the dose of the arsenite might be safely increased, I began on the 9th to give five drops instead of four.

11th. Specific gravity 1030, with 89 oz.

12th. Specific gravity 1030, with 87 oz.

13th. I did not take sp. gr. nor quantity.

14th. Examined both quantity and quality of urine. Specific gravity has fallen to 1029, and the quantity is 85 oz.

The symptoms of the patient are not by any means so urgent as in the beginning of the treatment. Thirst diminished, appetite less craving, diminished quantity of urine from 132 oz. to 85 oz., sp. gr. diminished from 1038 to 1029. There is one thing to be observed, that there has been a constant decrease in the quantity and sp. gr. of the urine, though it has not been regular; but when we see that the remedy has been in use only since the 4th day of May (10 days), we cannot but look upon the case with much hope. What the subsequent condition of the patient may be, cannot yet be known; but from the progress he has made, and his present condition, I look upon his case as very flattering.

HOSPITAL REPORTS.

WEST PENN HOSPITAL, PITTSBURGH, PA.

SERVICE OF F. LEMOYNE, M. D.

Reported by W. L. MILLS, M. D., Resident Surgeon.

Compound Fracture of Skull Followed by Abscess at Base of Brain.

Michael Corley, æt 9, of Mansfield, Pa., was admitted to hospital Saturday, Nov. 18, 1882, 9 p. m., having jumped from a coal car when in motion, and fractured his skull, five hours previous to admission. When admitted the boy was entirely conscious, and showed no evidences of compression. Patient had three scalp wounds, in two

of which were fractures; one merely a fracture in posterior upper part of left parietal bone, no depression; the other, the important one, was in right frontal region, wound extending from a point near median line, a little behind coronal suture forwards towards the outer canthus of right eye, about two inches in length. The scalp was entirely cut through, brain membranes ruptured, and brain substance oozing from wound. Anterior to scalp wound there was a marked depression. By use of probe, a large piece of frontal bone was found to be depressed, and so loose as to be easily removed by forceps, after wound was enlarged forwards. The removal was attended with considerable bleeding, and depressed fragment being so near the median line, fear was entertained lest the longitudinal sinus had been wounded. But after the removal, bleeding, which was venous, soon stopped. The wound was drawn together gently, but no straps or sutures used, only dry absorbent cotton applied so as to make slight compression. The fragment was from frontal bone, of an oval shape, an inch in length and nearly as wide, and both tables entire. The other scalp wounds were dressed with oakum and carbolized oil, and given free drainage.

The patient reacted well, and was soon put to bed and slept well all night. He asked continually for water, from time he came into hospital. All the following day the patient was quiet, but vomited whenever given water or milk. Nothing but beef-tea was retained, and only then when given in small quantities.

The following is a tabulated statement of pulse and temperature:

Morning.					
Nov. 19.	Pulse 120.	Temp. 101° F.	Pulse 130.	Temp. 103 $\frac{1}{2}$ ° F.	
" 20.	" 108.	" 103° F.	" 114.	" 102 $\frac{1}{2}$ ° F.	
" 21.	" 108.	" 103° F.	" 120.	" 104 $\frac{1}{2}$ ° F.	
" 22.	" 108.	" 102 $\frac{3}{4}$ ° F.	" 120.	" 103 $\frac{1}{2}$ ° F.	
" 23.	" 104.	" 101 $\frac{3}{4}$ ° F.	" 120.	" 103 $\frac{1}{2}$ ° F.	
" 24.	" 108.	" 103 $\frac{3}{4}$ ° F.	" 120.	" 104 $\frac{3}{8}$ ° F.	

Treatment.—On the night of admission,

R.—Calomel, grs. vi.
Bicarb sodæ, ℥ij.

was given. Also,

R.—Tr. veratri viridis, gtt. ij.
Liq. amm. acetatis, f̄ss.

every three hours, as pulse was 120.

Nov. 19. Gave calomel grs. x. in powder. Nov. 20. Had a good passage, vomited at intervals during day, but had a very good night. Slight discharge from compound fracture. Some decomposing brain substance was taken away, and part of wound drawn together. Breath very fetid. Asked continually for water. Was very restless, and bed-clothes tied down. Slept at intervals. When awake, perfectly rational. No difference in size of pupils.

Nov. 21–24. Condition about the same. Bowels moved naturally once or twice daily, stools dark-greenish. Headache was so little complained of that it was overlooked as a prominent symptom.

The only medicine given besides purgatives, (calomel in small doses) was veratrum viride to bring down pulse, and when it was found it did not tend to rise above 108 or a 120, the veratrum was stopped, Nov. 19th. Patient made a great outcry whenever head was dressed, but at other

times would roll about in bed, or jump out on floor, and evince no pain, so that little attention was paid to his cries.

Nov. 24th. Was particularly irritable and hard to dress head. Brain substance still protruding, but not so far as the day before. Talked wildly, always begging for water, and when in pain, always in Irish. Was somewhat flushed in face.

General condition so much the same that no particular attention was given the exaggeration of some former symptoms. Until 24th hope was entertained of recovery. Patient was drowsy and slept most of the day, waking at intervals and starting up wildly and asked for whiskey. Still no signs of compression or serious brain trouble, as he only showed signs of pain when head was dressed and this was attributed to irritability, as he at other times voluntarily jumped out of bed without evincing pain. No vomiting since 23d inst., and that only brought on by drinking water. Took and retained beef tea and milk.

Nov. 24, 8 P. M. Patient tore off bandage, and wound was much irritated by scratching or rubbing on pillow. Bandage reapplied, amid a storm of passion and Irish brogue, and hands were tied to prevent removal of bandage. He soon became quiet and slept.

10 P. M. Was sound asleep.

At 2 A. M. Nov. 25th. Night nurse noticed labored breathing, and before resident was waked and could get to ward, the boy was dead.

Autopsy made 14 hours after death.—The calvarium was removed, brain membranes cut through, and brain removed. The base of brain, particularly the pons, had an opaque appearance, was somewhat yellow and granular. The upper surface of brain showed no marked changes, except the meningeal veins were much congested. On raising up the cerebellum, an abscess was found lying in the fissure between the lobes of cerebellum, about the size of a chestnut, extending down to the fourth ventricle. The abscess was beneath the arachnoid membrane, and contained considerable yellowish pus. The lateral ventricles were filled with a purulent fluid and choroid plexuses somewhat congested. The wound in brain substance was sloughing, and extended some distance into tissue. There was a part as large as a walnut softened, but it in no way connected with abscess on lower surface. On raising the calvarium a marked depression was found in frontal bone, larger than, and lying towards, the median line, from hole left by removal of depressed fragment. The second fracture showed much larger on inner than outer surface, but no depression at all. The sudden death, with no premonitory symptoms of death, can be explained, I think, by abscess pressing on the upper part of fourth ventricle, which, as it enlarged, encroached on and pressed on the spot in floor of fourth ventricle, known as the respiratory centre, and suddenly stopped respiration. But why an abscess in under-surface, is another question? There was no fracture of base of skull discoverable on careful examination. A day or two before death, something peculiar was noticed about the boy's respiration, which was of a sighing character and very slow, but no more attention was paid to it, as at other times it was rather faster than normal. Headache was little complained of, and only did he

make resistance when raised up, which seemed to give him pain.

There was no time to examine lungs before body was removed, but as the central cause of death was found, the post mortem was entirely satisfactory to the resident physicians.

CITY HOSPITAL, PRAGUE.

Some Preparations of Gelatin in Diseases of the Skin.

BY PROF. F. O. PICK.

Professor of Dermatology and Syphilis in the University of Prague.

[Reported by LOUIS SCHWARZ, M. D.]

GENTLEMEN: A year ago I called your attention to a preparation called Chrysarobin gelatinum (Goa powder with gelatin), and recommended its use in psoriasis to you. The method of applying it is already known to you; the chrysarobin is prescribed in the quantity necessary, and is applied to the parts when in a fluid state by a brush. Jarisch, in referring to this mode of application and medicament, said the problem is solved and the beneficial effects of chrysarobin in psoriasis is established, and all evil effects are done away with. There are several points to be observed. The first is to obtain a method by which we can apply a medicament to a large surface at once, when necessary, for in many cases it is necessary. Formerly in such cases we were obliged to apply an ointment or plaster to one part alone. This required time and skill, for when an ointment was applied to one part, before the other part was finished the former was rubbed off; it was also necessary to bandage the entire body of the patient. This required time and skill, and annoyed the patient, and ointments always soil the underclothes, etc. By using the gelatin preparations, all these inconveniences are avoided. Following this plan of treatment, I have used other gelatin preparations with advantage—pyrogallol (pyrogallol acid), naphthol (the active principle obtained from tar), iodoform, salicylic, and carbolic acids. I will now demonstrate practically to you a case in which I used pyrogallol for psoriasis.

A. H., age 42, male, strong build, was admitted to my clinic two months ago with his entire body covered with psoriasis, so that only small parts of the skin were free from the disease. Having used pyrogallol in many other cases, and having good results from it, I applied a ten per cent. mixture of pyrogallol and gelatin to this patient's body. The mode of applying is the same as with other preparations. The patient, after having been bathed in water, a heated solution of the pyrogallol gelatin is applied to the parts with a small brush. As soon as it becomes dry, a small quantity of glycerine is applied to the surface to prevent the coating from cracking or peeling off. This coating being transparent, allows you to see the progress of the treatment without removing it. This is easily seen in this case: in some places the skin is perfectly normal. The dressing was applied in the beginning thrice weekly, and later twice weekly, with good results. These preparations can be applied by patients on themselves, and do not necessitate their being confined to a

hospital or their home. It is a clean preparation, can be easily removed, does not soil the clothes, nor prevent motion when applied over a joint; it is not expensive, does not crack or peel off. It is prepared in the following manner: dissolve 12½ of dry white gelatin in 25 of distilled water by a water bath, and while stirring add Goa powder, pyrogallol acid, naphthol, iodoform, carbolic or salicylic acids, in whatever quantity necessary, allow it to cool, and the cake will take the form of the capsule in which it was prepared (a porcelain capsule is preferred). You can then direct the patient to take the necessary quantity, place it in a china saucer, apply heat to it, and when in a fluid state apply to the parts with a brush. I am positive that any one resorting to this mode of treatment will never resort to the old manner of treating diseases of the skin by ointments, etc.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, April 12.

Dr. M. O'Hara in the chair.

Dr. C. M. Wilson presented the following specimens, the notes of which will appear in some future issue, owing to the author's failure to forward the papers to the Recorder:

Case of Invagination of the Ileum.

Case of Large Vesical Calculus.

Case of Multiple Vesical Calculi.

Dr. Guy Hinsdale presented three aneurisms, and a specimen of fracture at the base of the skull.

Case 1. Aneurism of the Arch of the Aorta.

Wm. G., a fireman, æt. 44, was admitted to the Episcopal Hospital September 16, 1881, suffering from pneumonia of the right side, associated with signs of pleurisy. It was noticed at the time of his admission that there was a slight diastolic murmur heard at the aortic cartilage, and that no radial or ulnar pulse could be felt upon the left side.

The pneumonia pursued its course until it ended in death on the eleventh day after admission. Eighteen hours before death occurred, however, after an attack of severe pain along the course of the sciatic nerve, he suddenly became unconscious, and his respiration puffing. His pupils were contracted, and his left arm rigid. His pulse became at once fuller and stronger than it had been since admission, there being ninety-six beats per minute. Fifteen hours before death the right side of the face was paralyzed. The radial pulse was smaller on the right side than on the left. The right foot was cold, and the posterior tibial pulse behind the internal malleolus was just perceptible. Respirations were forty per minute, and stertorous; sweat and urine profuse. Twelve hours before death respirations fifty-seven; temperature, 106.2°.

The patient remained essentially in this condition until his death. At the post-mortem examination, upon opening the thoracic cavity, the base of the right lung was found in the second stage of pneumonia. There was hypostatic congestion of

the left lung. But what at once threw light upon the later features of the case was the presence of an aneurism of the transverse portion of the arch of the aorta. The specimen shows a symmetrical dilatation of the vessel capable of receiving a large hen's egg. On examining the brain, clots, probably of embolic origin, were found in the right cerebral hemisphere, thus accounting for the paralysis which had been observed.

Case 2. Aneurism of the Common and External Iliac Arteries.

Johann B., a farmer, æt. 26, was admitted to the Episcopal Hospital October 27, 1882. His previous health was good; he denied specific history, and his habits were good. He was able to work until one week previous to admission, when he began to have a pain in the feet and legs, shooting up the body to the head. His skin was yellowish, his tongue coated, his urine did not contain albumen. There was oedema of the feet, and it is worthy of note that this had occurred on the right side four months before admission. His spleen was apparently enlarged; his lungs presented nothing abnormal. Systolic and diastolic murmurs could be distinctly heard all over the cardiac area, but most clearly at the right second cartilage, and transmitted over the left subclavian and carotid vessels. The heart was considerably hypertrophied.

Six weeks later, the attacks of pain in the right thigh and side, to which he had been subject ever since admission, became more frequent and severe. The murmurs at the aortic valve were systolic and diastolic, low, soft and confused. A distinct thrill was now felt; heart's impulse quick and trembling.

About one week before death a swelling occurred in the right parotid region, extending to the cheek and lower jaw. Subsequently a discharge, thin and purulent, took place from the ear, and the patient became unable to protrude his tongue. The oedema of the right leg returned and increased daily, extending up to the body, the whole leg being about three times the bulk of the other. The aneurism grew with great rapidity; the distention of the vessel and the overlying structures gave rise to the greatest pain. The patient was unable to lie down, and was always found in the sitting posture. The mind was clear up to the day of his death, which occurred two months after admission.

At the autopsy, upon opening the abdomen the aneurism was found very prominent, occupying the right side of the abdominal cavity and extending from the concavity of the liver to Poupert's ligament, a distance of about nine inches. The aorta bifurcated at the upper border of the fourth lumbar vertebra, the tumor arising from the common iliac artery one inch from the aorta. Its whole anterior surface was covered by peritoneum. The right kidney was elevated, lying upon the tumor's upper surface, the ureter passing over the convexity of the tumor and to the inner side. The psoas muscle and crural nerves were displaced and stretched to the outer side of the aneurism. The femoral artery emerged from the tumor one inch above the origin of the profunda.

Upon opening the sac a second sac was found within. No rupture had taken place. The cavities of both sacs were found filled with clots in

various stages of organization. The walls were leathery and large flaps of organizing clots were found attached to them. There were also *post-mortem* coagulations.

The line of the blood current could be determined by the passage of a catheter. This was found both from above and below to skirt the inner side of the tumor, and to pass through a comparatively short channel in its interior. Three of the bodies of the lumbar vertebrae were slightly eroded. The heart is hypertrophied; its weight fifteen ounces. The mitral valve is normal but the aortic valve shows exuberant vegetations which impede its action and which are very friable.

The specimen presented embraces the heart, the aorta, the aneurism with the right kidney upon its upper surface, the right femoral and the left iliac arteries.

Case 3. Aneurisms of the Abdominal Aorta and Left Common and External Iliacs.

Mary K., æt. 30, was admitted to the Episcopal Hospital Aug. 26, 1882. Her mother died in confinement, and her father, of heart disease. She had had three children; her husband was a bartender and had been treated for syphilis at a dispensary; but the patient herself denied specific history, nor were any evidences of it found. She had never been ill before.

Seven months previously she had pains in her left groin; these pains extended to the abdomen, and about five months previous to admission she noticed a small tumor in the hypogastrium, which pulsated and became painful on pressure. Three months later her strength began to fail; she became delicate and lost flesh. For one month the tumor had been prominent. Pain then came on spontaneously at intervals, and she had backache. She became weak and took to her bed. Two weeks before admission the left leg and thigh became painful and felt benumbed, and motion grew difficult and for a time was lost. Meanwhile the tumor increased.

Upon admission she was weak. Her face showed anxiety and suffering, and had a haggard and pinched look. The organs of digestion were not interfered with. Her lungs and heart were normal. On the right side of the abdomen a tumor was felt, one inch above the umbilicus, and extending from one inch to two and one-half inches from the median line, downwards two inches. It was painful on pressure, pulsated distinctly, and over it a distinct systolic bruit could be heard. A distinct notch separated this from a large, hard mass in the left iliac fossa, indistinctly pulsating, immovable, and not particularly painful on pressure. There was a faint *bruit*.

In the left thigh there was insensibility to touch over the distribution of the anterior crural nerve, while pain in the left knee was often so great as to deprive her of sleep. The urine did not contain albumen.

At the end of two weeks sensation was diminished on the left side as high as the edge of the ribs, and in the whole of the lower extremity, excepting the first and second toes. It was impaired over the buttock. Oedema of both legs occurred. The posterior tibial on the left side could scarcely be felt to pulsate.

September 13th the patient suddenly died. At

the autopsy the abdomen was first opened. There was no blood in that cavity. Upon the left side in the iliac fossa there was a prominent tumor of the size of a cocoon; over it lay the psoas muscle, which was spread out in the shape of a thin aponeurosis. The iliacus muscle was displaced. The psoas parvus was inserted in the tissue covering the tumor.

A fusiform dilatation of the aorta was then noted. The diameter of the aneurism was three times the normal diameter of the aorta. Commencing from a point seven inches above the bifurcation, it extended downward nearly five inches.

A second aneurism occupied the left iliac fossa, involving the left common and external iliac arteries. It was about six inches in length and was filled with old fibrous, laminated clots. The latter aneurism had opened posteriorly behind the peritoneum and against the iliac bone. There had evidently been ruptures previous to the one which finally caused the patient's death. There were found old as well as recent clots outside the aneurismal walls. There was no erosion of the bones. The femoral artery was normal, and no atheroma or evidences of syphilis observed, although the woman had been exposed to infection from a syphilitic husband.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Delhi or Oriental Sore.

Before the Epidemiological Society of London (*Med. Times and Gaz.*, April 14, 1883), Surgeon-General Murray read a paper on this subject. He stated that this disease had attracted little attention in India previous to the Mutiny in 1857-58, at which time the palace and city of Delhi were occupied by European and native troops. The military cantonment had previously been situated two miles outside of the city walls, and this disease was scarcely known amongst troops; but cases were occasionally heard of there, and at Mooltan and Lahore. After 1858 it was brought prominently to notice, as the troops in garrison at Delhi were attacked with great severity—from 40 to 70 per cent. were admitted into hospital suffering from the sore, whilst nearly half the regiments had slight sores which were treated out of hospital. The disease was very tedious and troublesome, though only in two or three instances fatal. When severe, or situated on a joint, it rendered the men unfit for duty; and when on the face it was very disgusting and disfiguring. This was illustrated by eighteen photographs of the disease situated in various parts of the body. In 1865 the Government of India appointed a commission to investigate the disease, to trace out its origin, and to point out a remedy. Dr. Murray was President of this commission, and he thus had an opportunity of accurate observation of the disease. It appears on exposed parts of the body—at first as a small pimple, like an irritated mosquito bite, and remains in this state for several days or weeks, sometimes even for months. It then slowly increases, and a thin fluid escapes from the top, which dries and forms a circular scab, gradually increasing in size and thickness. When this scab is removed, an indolent ulcer is exposed, with undermined edges, and lobulated granulations in the centre—in healthy subjects like raspberries, but paler and more blue in cachectic cases. These ulcers, when very broad, show signs of cicatrizing from the centre; in all

there remains a depressed cicatrix after healing. This is the natural course of the disease, which may last from six months to two or more years, when uncomplicated with leprosy, secondary syphilis, miasmatic fever, or a cachectic state of the body produced by other diseases or famine. When such diseases exist they are aggravated and rendered more fatal by combination with the one under consideration. The Delhi sore appears identical with the "yaws" of the West Indies, "parangi" of Ceylon, and the "bouton" of the eastern and southern shores of the Mediterranean. At Delhi, Mooltan, and Lahore the disease is endemic, and confined to residents within the city walls. The commission at Delhi, after patient investigation, formed the opinion that the Delhi sore is a cutaneous disease, of parasitic origin, and that the foul water of the city wells was the habitat of this parasite. The water of all these wells was excessively impure. In some, according to analysis at this time, the water contained from 45.375 to 123.200 grains of organic matter per gallon. The wells were then cleaned out, and from one a cartload of bones was extracted. It is probable they had not been cleared out for centuries. The water from them was only used for washing or bathing purposes. The wells in all the ancient cities of India are very impure, and if a germ or parasite in foul water is the cause of the disease, this would account for its presence in Mooltan, Lahore, etc., whilst the impure water in some of the tanks in Ceylon would furnish its habitat in that country. This germ or parasite finds entrance to the body, through bathing or washing, through an opening in the cuticle caused by any abrasion of the skin, and the most frequent channel is probably the surface of an irritated mosquito-bite, as the ordinary situation of the sores is on an exposed part of the person, as the face, hands, and arms, while the hairy scalp escapes. It was remarked that nearly all the dogs in Delhi suffered from this disease in the nose, whilst the body, which is covered with hair, and thus protected from mosquitoes, escapes. The germ, once introduced, develops in the cutis vera, exciting inflammation in the surrounding

part, and the sore results. Attempts were made to detect the germ microscopically, but in vain. Since then, Dr. Fleming and others have supposed they have discovered it, but as Drs. Lewis and Cunningham, after careful examination, failed to see it, implicit confidence cannot be placed in less experienced observers. Medical men differ in opinion regarding the contagious nature of the disease. To determine this point, six natives were inoculated from a dry crust, but no disease followed. They were then inoculated from a fresh sore, and twenty-three out of twenty-four punctures showed irritation like that from vaccination on the third day, which gradually extended till the sixth and tenth day, when remedies were applied to check the disease in four men, leaving it to take its course in the other two cases. Photographs of these cases show their similarity to the ordinary Delhi sore. The treatment recommended by the commission was to avoid using impure water, or, if that were impossible, to boil the water before using it, and to have all wells cleared out every year. The local treatment of the sore is directed to destroy the vitality of the germ by the application of the actual cautery in the earliest stage, and potential cautery—potassa fusa or nitric acid—and carbolic acid or mercury in more advanced stages, following the destruction of the specific disease by simple dressing, and washing with diluted carbolic acid.

The Dangers of the Parasitic Theory.

The *Medical Times and Gazette*, March 31, 1883, says:

Amidst the almost universal incense of admiration that awaits in France every fresh announcement of the results of M. Pasteur's researches, it is as well to note that some observers are not so easily satisfied. In the *Progrès Médical* for March 10 we find the following criticism, from the pen of M. Jousset de Bellesme:

"We were not among the last to raise our voice against the application of the theory of microbes to medicine, and to signalize the serious inconveniences which might be induced by the introduction of these doctrines into pathology. When we showed in this journal* that these theories, almost entirely hypothetical, engaged medicine in an unfortunate direction by attributing to morbid phenomena a simplicity that they are far from possessing in reality, and by leading to treatment both irrational and dangerous for the patient, we were taxed with exaggeration and foregone conclusions. And yet we were but the echo of a large number of clinicians, and so true is this the case that at the present time a reaction against these tendencies has set in in the school of French pathologists. Practitioners who pursue therapeutics in an impartial manner, and so to say experimentally, had evidently received M. Pasteur's theories in the hope of deriving from them an excellent means of treating disease. In no other way can be explained the success of the parasitic doctrine, and the somewhat premature prepossession of which it became the object, chiefly on the part of the young medical generation. It is such a great point, in order to combat a disease, that we should be aware of its cause, and M. Pasteur

was so affirmative, that a good number of practitioners came to the conclusion that from the moment that infectious diseases were known to be caused by invasion of microbes, it sufficed to kill the microbe in order to cure the disease. All those who have reasoned in this fashion have only, together with M. Pasteur, forgotten one thing, which yet deserves well that it should be taken into consideration—the patient. Yes, unfortunately, there is a patient in this question of microbes applied to pathology. It is not so simple a matter as in the laboratory, where the microbe is regenerated and strengthened in its chicken-broth. We have only to pour on it the blackest of poisons or the most energetic of antiseptics, and all disappears—all except the germs of these singular bodies, if we are to believe M. Pasteur. But when we have a patient in our hands we scarcely can treat him, however stuffed with microbes he may be supposed to be, as we would the chicken-broth, and deluge him with floods of carbolic or salicylic acid. Still, there have been found practitioners who have dared to do this; and Prof. Jaccoud, whose high authority none will contest, has taught us the results of these audacious attempts in the treatment of typhoid fever. It has come to pass just as might have been anticipated; the employment of antiseptics in large doses has introduced into the statistics of the mortality of typhoid fever an element which formerly only figured there very exceptionally—sudden death. It is but too certain that from the moment the idea is started that typhoid fever depends upon a microbe developed in the economy, a resort to antiseptics necessarily takes place. Those are employed which are best tolerated by the economy—salicylic acid, sulphate of quinine, and even carbolic acid. As the administration of these in small doses leads to no result, logic requires that the doses shall be increased and pushed on until this mischievous microbe is annihilated. Unfortunately, while on this road, as already stated, the patient is forgotten; but he, in his turn, does not forget, when the dose is sufficient, to die suddenly. Sudden death, then, is one of the results which may spring up in the art of healing from the discoveries of M. Pasteur; and on reflection, we cannot but regard it as highly extraordinary that doctrines which may lead to such results have been able to attain so great a vogue in medical practice. For, even supposing that the theories of M. Pasteur are exact, and that typhoid fever is really the fruits of an invasion of microbes, there is evidently no advantage to therapeutics to be derived from the knowledge of this fact; for this very simple reason—that the organism would not tolerate sufficiently strong doses of antiseptics to kill in the blood or amidst the tissues the lower parasitic organisms, the resistance of which to these agents is greater than that of the more highly differentiated cells of our economy. And as to believing that an antiseptic will be found which destroys bacteria without attacking the histological elements in man, it is to fall into a great illusion, and to misunderstand the laws of general physiology. The more an organism is differentiated, the less does it resist external agents capable of injuring it; consequently, we may affirm that, of all organic cells, it is well nigh those of bacteria which are most resistant to

* *Medical Times and Gazette*, April 29, 1883, page 451.

the action of poisons and antiseptic substances. However this may be, certain it is that typhoid patients to whom antiseptics are administered in large doses die suddenly, and quinine itself makes no exception to this rule. And thus Prof. Jacoud, in his lecture on the treatment of typhoid, protests forcibly against these therapeutical temerities."

On the Use of Anæsthetics During Labor.

In a paper recently read before the East Surrey District of the South-eastern Branch of the British Medical Association (*Brit. Med. Jour.*, May 5, 1883), Dr. Savill indicates what he believes to be the main precautions, the observation of which would render the use of chloroform perfectly justifiable.

1. There are certain women who have a tendency to flood at every confinement, and others in whom there seems to be an already too great relaxation of fibre—weak anæmic females in their eighth to tenth confinement; and to these it would be unadvisable to give chloroform, except for necessity. Happily, it is not these women who suffer the most pain, but rather those strong, healthy primiparæ whose pelvis and general build approximate to the masculine type.

2. We should not give it when labor is complicated with severe vomiting, or with acute heart or lung disease, unless there be imperative call for it.

3. It should not be given to the full extent, except for operation, convulsions, or spasm of the cervix; and then it is most necessary that one person should devote his entire attention to it.

4. The inhalation should be stopped directly we find the pulse becoming very weak, or the respiration irregular.

5. Anything which makes us suspect a fatty or enfeebled cardiac wall should make us cautious in the use of chloroform. Here, as in cases other than those of labor, it is not the most extensive valvular disease (so long as it be attended by compensating hypertrophy), but the atrophied or degenerate wall, that constitutes the source of danger. Unfortunately, the signs of these conditions are subtle and uncertain. Fatty heart may be suspected by an exceedingly feeble cardiac impulse, combined with an almost inaudible first sound; or attacks of dyspnœa, vertigo, and syncope, in the absence of anæmia, or valvular lesion; or the copious deposit of fat in other parts of the body, and the occurrence of dropsy without adequate cause. A dilated heart may be suspected by increased area of præcordial dullness, combined with epigastric and venous pulsation, and a want of correspondence between the violence of the cardiac impulse and the strength of the pulse. Pericardial adhesions also form a great source of danger. They may be suspected when the heart's apex is fixed above its normal position, and does not shift with respiration; or when there is depression instead of protrusion of intercostal spaces over the position of the apex, giving a wavy character to the cardiac impulse.

6. In all cases, we should take extra care to prevent the occurrence of hemorrhage after birth; by giving a full dose of ergot when the head reaches the perineum: by ceasing the chloroform immediately it is born; and by rousing the patient from her lethargy as soon as possible.

Diet in the Treatment of the Gouty Dyscrasia.

At a meeting of the New York Academy of Medicine, held February 15, Dr. William H. Draper read a paper with the above title.

Dr. Draper's observations went to show that gouty subjects were unable to digest the carbo-hydrates. This kind of food produced acid and flatulent dyspepsia, and the very symptoms which usually preceded an explosion of acute gout. In the children of gouty parents over-indulgence in amylaceous and saccharine foods was almost sure to be followed by evil consequences, and great caution in the use of these was one of the surest means of diminishing the liability to acute attacks in those already subject to the disease. The diet, then, in the gouty dyscrasia was to be in the main similar to that required in glycosuria, although it was not necessary that the abstinence from carbo-hydrates should be so strict as that demanded in diabetes. The patient should, therefore, refrain as much as possible from saccharine, starchy, and fatty foods, and especially from all fermented alcoholic beverages. Distilled liquors did not have the same effect, as seemed to be shown by the fact that gout was much more prevalent in England, where beer and stout were universally partaken of, than in Scotland, where whiskey was the drink most indulged in. It was also said that gout was rare in Russia and in Poland, where spirits are principally used. In regard to the effect of wines there was, of course, a difference according to the kind used. Sherry, port, and madeira were the most injurious, but the heavier clarets and burgundies were also to be carefully avoided. The effect of cider was well recognized in the production of gout, and in New England, where it was a common beverage, it often led to the development of the irregular forms of the disease.

All drinks containing any unfermented sugar were to be excluded, and if the patient insisted on taking wine, he would have to confine himself to the driest of the dry champagnes, hock, or light claret. But even these could not always be trusted, and the safest alcoholic beverage that could be taken was a very diluted spirit. Indulgence in saccharine food ranked next to that in wine and beer in danger, and it was an important point to observe that this excluded the use of many fruits, such as strawberries, apples, and oranges. Next in importance in this connection came amylaceous articles of diet; but it was not necessary that these should be entirely abstained from, but only that they should be eaten in moderation. They did most mischief in those inclined to obesity and who led sedentary lives. All kinds of salads, tomatoes, and the various succulent vegetables free of starch, could be taken with impunity. In obstinate cases the milk diet was of the greatest utility. The digestion of the carbo-hydrates was always more or less impaired in gouty individuals; but if an active outdoor life were engaged in, it was not necessary to look after the diet so carefully. The gouty man who remained in-doors much of his time, however, would do well not to live upon potatoes and puddings.

Iodoform Suppositories for Puerperal Septicæmia.

Before the Medico-Chirurgical Society of Montreal (*Med. News*, March 3, 1883):

Dr. Alloway presented the records of six cases of puerperal septicæmia, three of which had been treated by a new method, viz., the introduction into the uterine cavity of iodoform suppositories. He referred to the care and anxiety which these cases caused to the attendant, the frequent visits necessary if the ordinary method of repeated intra-uterine injections is followed, as in general practice the assistance obtained is rarely skilled enough for this. The advantages of iodoform in general surgery were now fully recognized, and it occurred to him that they might be extended to the treatment of the raw placental surface and to the lacerations and bruises of the passages. The site of a separated placenta had been well compared to the stump of a limb after amputation. (With this remedy we had the advantages not only of a topical action, but, applied in the manner directed, the effect was continuous, and the vapor, or whatever it was, given off, permeated to all parts. Too often, with injections, the superficial parts were cleansed, and in an hour or so, unless repeated, the discharges were again fetid. He believed that with the iodoform we could get a more effectual disinfection of the intra-uterine cavity in these cases than with the ordinary solutions, and the trouble of constant injections was completely obviated.) The author referred to the current views on septicæmia, particularly to the formation of a virus by the bacteria in the decomposing discharges, and suggested that if, as Binz has shown, the iodoform controls the activity of the protoplasm of the colorless blood-corpuscles, it may do the same with the bacteria. In carrying out the treatment he used a Sims' speculum, washed out the uterus first with plain or carbolyzed water, and then, with a tent-inserter, passed the suppository far up into the fundus. He used them of the strength of ten, fifteen, or twenty grains, and usually introduced one night and morning. No poisonous effects had been noted.

The Pathology and Treatment of Tuberculosis.

At the Second German Congress of Internal Medicine, Prof. Rühle, of Bonn, spoke as follows, *Med. Record*, May 19, 1883:

He reviewed and endeavored to answer the arguments against the view that the bacillus is the specific cause of phthisis. Accepting it as a cause, he urged the use of disinfection, isolation, and antiseptics in the treatment and prevention of the disease. His conclusions were: 1, human tuberculosis is an infectious disease; 2, the bacillus discovered by Koch is its special cause; 3, the fact that pulmonary tuberculosis may be transmitted from man to man by contagion is established; the exact method is not certainly known; 4, tuberculosis in man and animals is identical; 5, the therapeutics relate chiefly to prevention, but the best methods of prophylaxis cannot yet be formulated.

Dr. Fraentzel, of Berlin, related the results of the experiments made in connection with Koch and Gaffky with the

ANTISEPTIC METHOD OF TREATING PHTHISIS.

They had employed inhalations of menthol camphor, naphthalin, anilin, etc., but with negative results.

Professor Klebs, of Zurich, believed it demonstrated that bovine tuberculosis was communicable to man. He thought that a certain predisposition must exist in order that contagion occur, and reaffirmed his old view that the intestinal tract was often the place where the infective virus entered.

Professor Hiller, of Berlin, had made injections into the lung tissue (in cases of phthisis) of corrosive sublimate, bromide of ethyl, and alcohol, but without any result.

Dr. Schott, of Mannheim, recommended salicylate of sodium and sulphurous acid as antiseptics in tuberculosis.

Dr. Zeigler, of Tübingen, described his views of the way in which the tubercular virus enters the system. He thought that the entrance occurred through three channels, viz., the blood-vessels, the lymphatics, and the lungs. In accordance with this we may distinguish

THREE TYPES OF TUBERCULOSIS.

When it enters by the blood-vessels we usually have general miliary tuberculosis, but in rare cases, especially in children, tubercular foci are formed in the lungs, making the disease resemble a localized tuberculosis.

The second form, in which the lymphatics take part, is that which is generally produced by inhalation. A tubercular lymphangitis is excited. The tubercular foci thus formed enlarge, then soften, and their products may be carried further (1) by the lymph paths; or (2) by the blood-vessels, causing an embolic tuberculosis; or finally (3), directly along the bronchi. In this way, or by direct infection, we find developed the third type, or bronchial tuberculosis.

Professor Rühle, in concluding the discussion, called attention to the fact that not a voice had been raised against the view that tuberculosis was an infectious and parasitic disease.

Hypodermic Injections of Ether in cases of Imminent Death from Hemorrhage.

The Paris correspondent of the *Med. Press*, (Feb. 14, 1883), writes as follows:

M. Georges Hayen, of the St. Antoine Hospital, read a paper on the "Value of Hypodermic Injections of Ether in Cases of Imminent Death from Hemorrhage." In his report he said that transfusion of blood, although frequently practiced abroad, had but few partisans in France; yet if medical men would only give it a fair trial, he was sure their verdict would be in favor of it. He could not help thinking that the criticism made upon the operation was much exaggerated. His colleague, M. Verneuil, gave it as his opinion that transfusion of blood was a difficult, dangerous, useless operation; that the blood, acting only as a stimulant, could be easily replaced by subcutaneous injections of ether. Emanating from such a high authority, this assertion gave him food for reflection. Could it be true that transfusion could be replaced by an operation as easy and relatively as inoffensive as the injection into the cellular tissue of a few drops of ether? Immediately he determined to put the merits of the proposition of M. Verneuil to the test, and for that purpose he experimented on a lot of ordinary

street dogs, and the result was completely in favor of transfusion. He bled until convulsions commenced, indicating the approach of death, and although he injected ether four times, the dog died. In an exactly similar case he performed transfusion, and the dog recovered. Other experiments continued to prove the uselessness of ether, and, on the contrary, the exceeding great value of transfusion, which in nearly every case operated complete resurrection. As to the danger of the operation, it was greatly exaggerated, but he insisted on the absolute necessity of employing non-defibrinated blood. On the contrary, he considered that blood injected without its fibrine was not safe, and did not give good results.

The Trance Condition in Surgery.

The *Med. Gaz.*, May 19, 1883, says the activity of interest manifested in the curious psychological phenomena of mesmerism has awakened widespread inquiry regarding the nature of the trance state, and has established some few truths, along with dissipating many errors.

Not the least important of the questions that have been suggested by a study of these psychical phenomena, and by far the most interesting to the surgeon, from a practical point of view, is the possibility of performing surgical operations on patients in this state, with the same immunity from pain as is obtained by the use of ordinary anæsthetics.

An experiment was recently made by some New York physicians to aid in elucidating this problem, the result of which tended to establish the fact that on patients who are suitable subjects for the induction of the hypnotic state, it was practicable to perform minor surgical operations without awakening consciousness.

The operation done, was the removal of hypertrophied membrane from the nasal septum by the wire snare.

The rapidity with which the mesmeric state may be induced, as well as dissipated, and its freedom from disagreeable after-effects, as compared with ether, would render it a valuable substitute for that anæsthetic in minor surgery, if further experiments tended to confirm those already made.

The chief objection would seem to be that its application would necessarily be limited to those few who could readily be mesmerized, and that surgeons would either have to acquire, if they did not possess, the mesmerist's art, or add a mesmerist to their staff of assistants.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—With the May number, *The Century* begins a new volume, and announces some changes in its arrangements. Its contents are of usual interest, being the continuation of Frank H. Cushing's "Adventures in Zuni;" "The Christian League of Connecticut," by Washington Gladden; "The

Aboriginies and the Colonists," by Edward Eggleston; W. D. Howells' serial, "A Woman's Reason;" and "The Father of American Libraries," by Bunford Samuel. Frank R. Stockton has a bright little story, "Pomona's Daughter." The poetry is good, and the illustrations of the peculiar style lately adopted by *The Century*, are unusually spirited.

—*St. Nicholas*, of The Century Co., N. Y., and conducted by Mary M. Dodge, is the brightest and most charming of young people's magazines. The May number is a most interesting one, exquisitely illustrated, and is of itself worth half the yearly subscription of \$3.00.

BOOK NOTICES.

The Practitioner's Ready Reference Book. By Richard J. Dunglison, A. M., M. D. Third Edition. Philadelphia: P. Blakiston, Son & Co. Cloth, 8vo., pp. 529. Price \$3.50.

A great many points that the physician wants to look up are here collected into a moderate compass, and set forth with perspicuity and accuracy. Already the work has passed through two editions, and in preparing the third the author has added a mass of useful material, and carefully revised what was contained in the former issues. We do not doubt but what it will continue to enjoy its popularity, as it well deserves.

Insanity: Its Causes and Prevention. By Henry Putnam Stearns, M. D., etc. New York: G. P. Putnam's Sons, 1883. 8vo., pp. 248.

The subject which is treated of in this volume is one of great weight—perhaps increasingly so. That mental disease is gaining in proportionate frequency year by year is the opinion of many, and among others of Dr. Stearns. It is his object to analyze the causes, remote and immediate, which produce it, and to suggest when and how they can be remedied. He discusses with this view the insane diathesis, the influence of education, industrial and moral, heredity, consanguineous marriages, alcohol, tobacco, sex, poverty, religion, sleeplessness, etc. Few men can write on these subjects without betraying the personal prejudices of their own bias, and our author is not one of that few. It is often evident that his views are founded less on observation of what is, than on opinion of what ought to be. Yet his book contains a great deal that will be instructive to the mass, and occasionally suggestive to special students. His style is agreeable, and the volume is neatly manufactured.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

HOW TO PREPARE THE PANCREAS FERMENT.

Many preparations are sold to-day to the medical profession as pancreatin, respectively as the pancreas-ferment. But usually the physician is disappointed in their effect: why? we intend showing in the following. Generally the manufacture of the remedy mentioned is a very simple procedure and the result, therefore, an unsatisfactory one. "Accidentally while speaking of the chemical nature of unformed ferments, Dr. O. Löw (Ueber die chemische Natur der ungeformten Fermente. Pflüger's Arch., xxvii. p. 203) describes the manner of preparing a really pure pancreas-ferment, and we here translate the same for the benefit of those who wish to manufacture such an article. They will see also that the procedure is by no means so simple.

One kilo of a pancreas-gland, cut up finely, is left standing for a day or two at a temperature of 14°; one and a half of its weight of 40% alcohol is then poured over it and left standing for two days. The somewhat thick mass is then pressed through a hair-sieve, the fluid is isolated and directly precipitated with a mixture of two vol. absolute alcohol and 1 vol. ether; the precipitate is washed with absolute alcohol, pressed, the residue dissolved in water, and again precipitated with alcohol, ether, and the residue dried over sulphuric acid. This raw ferment is now dissolved in water, filtered, precipitated as thoroughly as possible with diluted acetate of lead, the filtered part freed again of lead, precipitated with absolute alcohol, etc.

The gain of pure ferment amounts to about 2 p. m. of the gland. The ferment procured in this manner is a snow-white powder, easily soluble in water, and forming then a fluid the reaction of which is very weakly acid; it digests fibrin energetically, and possesses powerful diastatic properties—is therefore a mixture of two ferments. The solution shows in general the reactions of an albuminoid substance, gives Millon's reaction, the biuret-reaction with potash and copper sulphate, but does not coagulate by heat, and becomes slightly turbid only with ferrocyanide of potash

and acetic acid or continues even clear, and the elementary analysis gives the following figures : $C_{52.75}, H_{7.51}, N_{16.85}, O + S_{23.19}$ p. m.; this coincides with that of albumen, and its behavior to reagents is very similar to that of the pepton.

A pancreas-ferment, if carefully prepared in the manner and by the method described above, would produce perhaps more satisfactory results in troubles of indigestion, than most common pepsin-preparations do now. But the pancreatin as at present generally sold by the drug trade is a remedy totally unreliable. We hope that some enterprising manufacturer will take the pains of preparing a really pure pancreatin, in which case we do not doubt that it would soon take the place of pepsin. Whenever prescribing the latter, we involuntarily do so from the idea that the change of albuminoids into albuminose wants assistance, while really the hydro-carbons and other aliments, digested by the pancreas-ferment, may be at fault.

ANÆSTHESIA BY CAUSTIC APPLICATIONS.

M. Jules Guerin, at a recent meeting of the Academie des Sciences (April 16th), related the first case where local insensibility, sufficient to perform an operation of gravity, was obtained by the use of caustics. It was a case of scirrhus tumor of the breast, presenting two small crateriform ulcerations, non-adherent at the base, and unaccompanied by any glandular enlargements in the axilla.

Her general health was not favorable; she had been troubled for a long period with catarrhal bronchitis, and presented symptoms of heart disease, so that it was not judged advisable to submit her to a prolonged sèance of anæsthesia.

About two centimeters from the circumference of the tumor was applied an elliptic layer of Vienna paste about two centimeters wide, completely surrounding the tumor.

After about a quarter of an hour, the patient said that all the pain she felt in the tumor was gone.

Five minutes later the caustic was removed, and

a wide dark surface was found where it had been applied.

A platinum thread was passed under the tumor from below upwards, so as to draw the breast out from the chest wall during the operation. An incision was then made circularly all around the breast on the cauterized line, and the breast itself detached, partly with the handle of the scalpel, partly with the scissors, with very little hemorrhage—only one arteriole required a ligature—and without the patient making any complaint of suffering. The operation succeeded, there was no fever, the excavation gradually filled in; the cauterized band at its circumference, at first dry and preventing the passage of the liquids of the wound, gradually became detached and disappeared.

PRESENCE OF MERCURY IN ANIMAL SUBSTANCES.

The method which for many years had been adopted to demonstrate the presence of mercury in the urine was originated by Ludwig, and received his name. Recently Dr. O. Lehmann disputed the correctness of the test. Dr. H. Paschkis has now given this subject a careful investigation, and he considers, in his article in the *Ztschrift. f. Physiol. Chemie*, vi., p. 495, Ludwig's method as one not only to be easily executed, but also perfectly sure and safe; 0.2 milligr. chloride of mercury were demonstrated in 400 ctns. urine by this method. P. made one modification of L.'s procedure; he washes the zinc-dust with an alkaline water, and heats the dust purified in this manner. The result is satisfactory.

According to Paschkis, Fürbringer's procedure can be executed with still greater rapidity and ease, it being also simple; but the test is hardly so delicate, though 0.2 milligr. chloride of mercury can also be demonstrated in 400 ctm. urine. The simplest method, however, of all, is the employment of goldleaf to digest the urine to be tested for mercury; the whole is pressed into a paste, washed with alcohol and ether, and then heated in a glass tube with sufficiently thick walls. The recommendation of Lehmann, with muriatic acid

and chlorate of potassium to destroy the organic substances contained in the urine, P. considers to be totally superfluous and unnecessary.

PROSTITUTION IN FRANCE.

In a recent work by M. Armand Desprès, of the Paris Faculty, devoted principally to statistics, and written in opposition to the recognition and licensing of the social evil by the state, the following figures are given :

There are in France 15,057 registered prostitutes, 7,859 belonging in maisons de tolerance, which number 1,328; 7,198 prostitutes are what is termed en carte—they live in their own rooms and appear at certain stated times (once monthly) for examination. Besides this prostitution recognized by the law, there is another; the individuals exercising it escaping as best they can the attention of the police. The number of free prostitutes is thought to be about 41,000.

M. Desprès asserts that where prostitution is regulated by the state, and the danger from infection thus obviated, marriage is thought of later in life, and increase of population reduced to a minimum.

D. S. S.

"Within the last dozen years, nearly all of the Universities and Colleges of Physicians in the United Kingdom have instituted special diplomas in state medicine, or certificates in sanitary science."

So says Dr. Charles A. Cameron in his address on "Sanitary Legislation and Administration at Home and Abroad," read before the First Meeting of the Sub-section of Public Health of the Academy of Medicine in Ireland, February 9 (*Med. Press*, February 28, 1883), and so we hope we can soon say of our American Universities and Colleges.

When we can chronicle the fact that our colleges have instituted regular chairs of hygiene, and when we have found worthy men who have added to their other titles that of D. S. S. (Doctor of Sanitary Science) then can we confidently look for intelligent preservation of health and avoidance of disease.

IODOFORM DRESSINGS IN LESIONS OF THE PERITONEUM.

The use of iodoform in cases of ovariectomy and other operations in the abdominal cavity has given exceptionally good results, but exposes the patient to the serious risks attending absorption of the toxic agent.

To avoid this, M. Kuster recommends for peritoneal dressings a layer of sponge impregnated with iodoform, so that but a very small quantity of the drug remains on the surface of the sponge.

In this way there is enough iodoform to insure perfect antisepsis, and not sufficient to induce toxic accidents through its absorption.

A tampon containing iodoform should at the same time be introduced into the vagina.

NOTES AND COMMENTS.

An Interesting Case of Injury to the Heart.

A laborer of herculean strength and immense build, received a wound in the region of the heart $\frac{3}{4}$ ctm. inside of the mammary line, 2 ctm. from the nipple, and $4\frac{1}{2}$ ctm. from the left margin of the sternum. The wound was 2 ctm. in length, and had been made by a knife, the blade of which had penetrated for a distance of 15 ctm. into the body of the patient. Immediately after the injury, the man walked on fifteen steps further, and not until a few hours after the trauma was he taken to the hospital, where the dulness over the heart, and the heart-sounds were found unaltered, but the pulse was very small for a man of his size. In the hospital it was supposed that the lung and perhaps the pericardium, but surely not more than the left coronary artery of the heart, had been injured. But the very next day, under symptoms of intense restlessness and dyspnoea, the pulse became still smaller; later in the day, a dulness developed itself, reaching from the heart to the spine, and under increasing restlessness and dyspnoea, the patient died thirteen hours after the injury had been received. The post-mortem examination revealed the following: The left pleural sac was widely open, the lung uninjured, the wound penetrated horizontally through the pericardium and the anterior wall of the right ventricle. The wound channel ended in the posterior wall, passing, therefore, fully through the ventricle. The pleural cavity contained an enormous quantity of blood, so did the pericar-

dium; in both, most of the blood was coagulated, but the right pleural cavity contained about 450 ctm. fluid blood. Death had taken place, therefore, in consequence of slow oozing out of blood into the pleura, and Dr. Husner, who reports the case in the *Deutsche Med. Wochenschr.*, 1882, No. 5, thinks that if adhesions had formed around the orifice of the wound in the heart, the patient might have been saved.

Œdema of the Temporal Region an Important Diagnostic Sign.

An unmarried lady, æt. 31, suffered for a long time from a purulent discharge of the ear and polypus-formation in the meatus on the right side. Suddenly there developed itself, with intense pains, deep in the ear, and spreading over the whole right side of the head, a swelling over the mastoid process, and synchronously a *diffuse hard œdema* in the region of the right temporal bone of the zygomatic process with slight redness of the integument. Soon unconsciousness set in, the pupils reacted evenly but sluggishly; the pulse was full, intermitting here and there, 56 per minute. Notwithstanding the discharge of a considerable quantity of fœtid pus by incision of the abscess over the mastoid process (carious in nature), death set in under progressing stupor. The post-mortem examination evinced meningitis caused by the otitis, complicated by phlebitis and thrombosis of the lateral sinus. The case is reported by Dr. S. Moos in the *Zeitsch. f. Ohrenhkd.*, xi., p. 242. M. had some time previous a similar case, where the œdema of the temporal region also enabled him to make a correct diagnosis, and to base the fatal prognosis upon.

A Case of Obscure Fatal Nervous Disease.

A woman aged 55, who had never given her health a thought, for it had always been excellent; but who had had a great deal of trouble, finally broke down with symptoms of partial paralysis of motion in the tongue, palate, portions of the face, the muscles of the back of the neck, and left shoulder.

At the end of six months' rest, these symptoms disappeared almost entirely, but returned more more rapidly than they went; and two months later, about seventeen months after the first appearance of paralysis, death ensued during sleep.

Dr. F. C. Shattuck, who reports the case in the *Boston M. and S. Jour.*, May 17, 1883, asks:

1. Was the original diagnosis of functional and recoverable disorder, made by me and confirmed by Dr. Webber, correct.

2. If it was correct how are we to explain the fatal result without the advent of any new symptoms, but simply under an aggravated return of the old?

3. If it was not correct, what was the nature of the disease? Can it have been an anomalous case of glosso-labio-laryngeal, or bulbar, paralysis?

Subcutaneous Nodules and Cardiac Vegetations.

Whether the existence of subcutaneous nodules has any bearing on the prognosis of disease of the mitral valve is a question recently discussed by Dr. Drewitt before the West London Medico-Chirurgical Society (*Med Press*, May 9, 1883), Drs. Barlow and Sainer first called attention to these bodies in children before the International Medical Congress. Dr. Drewitt exhibited a boy aged nine years, who had had rheumatic fever and who had in the knees, elbows, knuckles, and occiput about thirty-six small, slightly movable, painless bodies lying in the fibrous tissues immediately beneath the skin. He thought from the fact that in a case which he had recently shown at another society, where a loud, harsh, mitral murmur almost disappeared when a crop of nodules subsided, that these apparently unimportant bodies have an important bearing on the prognosis of disease of the mitral valve.

Dr. Dyce Duckworth (*Med Press*, May 2, 1883), relates another case which yielded gradually to iodide of potassium.

Peptonuria.

What becomes of the peptones is yet an unsettled question, though there is some ground for holding that they are converted into glycogen by the hepatic secretion. If this be true, then their presence in the urine would seem to indicate faulty hepatic digestion. Dr. Charles Henry Ralfe reports three cases in the *Brit. Med. Jour.*, May 12, 1883, in which he found peptones in the urine, in two of which the prominent symptoms were those of dyspepsia, after the relief of which, the peptones disappeared.

In order to insure the development of the characteristic reaction, the following mode of procedure must be adopted. A drachm of Fehling's solution is to be introduced into a test-tube, and then a drachm of urine is to be floated carefully on the surface. Where the urine comes in contact with the alkaline copper solution, a thick zone of phosphates will form, above which, if peptones be present, a red halo will appear, not

violet, as stated by Dr. George Johnson, but a decided claret, or ruby red.

Nature and Varieties of Gout.

Ebstein in his exhaustive and original work on this subject (*Die Natur und Behandlung der Gicht*), concludes that the formation of crystals of urate of soda in the different organs is not the only characteristic lesion of gout. He considers that these crystals are deposited only in tissues that have primarily undergone a form of necrosis, induced by the action on the elements of the tissues of urate of soda, dissolved in the blood and liquids bathing the affected parts.

He describes two forms of gout: the first, most frequent, affecting the joints alone and unaccompanied by any renal lesions. The second or renal form is more rarely observed, but of much greater gravity; the articulations in this form are secondarily affected, and never to such a degree as in the first form.

A Symptom of Lesion of the Sympatheticus.

Dr. E. Clément (*Rev. de Méd.*, 1882, No. 10,) had the opportunity of observing two cases, in which one characteristic symptom existed which proved lesion of the sympathetic nerve. In the first case a carcinomatous growth had caused softening of the dorsal spinal cord at the seventh dorsal vertebra; the sympatheticus was included in the new growth. When C. passed with a dull instrument over the skin, not only a redness appeared over the place touched but also a swelling similar to the one noted in urticaria. This could be induced all over the surface of the body.

In a second case the diagnosis was morbus maculæ Werthofii. Here the same symptom was noticed, with the difference that these phenomena appeared by themselves. C. believes that in both cases a lesion of the sympathetic nerve caused the symptom, which is the opinion of many observers.

The Difficulty of Detecting True Syphilis in a Woman.

Dr. C. H. F. Routh considers the difficulty extremely great. He holds (*Med. Press*, May 9, 1883,) that there is but one true syphilitic and venereal sore capable of contaminating the system, and that the other is a purely local affection, a pseudo-syphilis, chancroid, or dirt sore. This true sore is oftentimes exceedingly minute and benign in appearance and behavior. It may be situated on the cervix uteri, the vulva, or the mammae, and unless a most careful examination is made, aided

by a true history from the patient, its existence is very likely to be overlooked, with the result that we are left in great doubt and uncertainty as to the true nature of the constitutional manifestations which supervene.

Permanent Asthma.

Prof. Germain Sée (*L'Union Méd.*, March 6, 1883), regards asthma as made up of three elements: nervous, catarrhal, and emphysematous. When the latter condition is unduly prominent, we have permanent asthma.

His method of treatment, for which he claims excellent results, consists in the exhibition of full doses (thirty to forty-five grains per diem) of iodide of potassium. Under its continued use for some length of time, the asthmatic exacerbations disappear, and the permanent dyspnoea is greatly lessened, if not entirely controlled. It is sometimes useful to add from three-fourths to one and one-half grain of opium to the daily dose of the potassium salt, to prevent iodism.

Diet vs. Diabetic Coma.

In the report of a very interesting case of diabetic coma in the *Brit. Med. Jour.*, May 12, 1883, Dr. J. W. Bond says: "It is somewhat surprising that, in the published cases of diabetic coma, little is said as to the diet. In this, as in two other cases of which we have exact information, diabetic coma has supervened on the adoption of a diet rich in albumen and poor in starch. We think it noteworthy that the addition of extra mutton to a generous albuminous diet, in the case just described, was accompanied by an increased daily passage of over forty ounces of urine. On the first day after this increase of diet, the amount of urine rose from ninety-six to one hundred and sixty-eight ounces."

Cold-taking.

The past winter has been one of unusual severity in the West; in Iowa during January, the mercury was below zero on twenty-five days, and on two occasions it went to 33° below, yet Dr. Z. Carey, of Bangor, Iowa, notes in the *Cincinnati Med. Recorder*, May 15, 1883, that the people were singularly free from "colds" and catarrhal affections. But as soon as the warm weather commenced, there was a regular epidemic of catarrhal diseases, such as sore throats, bronchitis, lung fever, etc. This observation tends to emphasize, what we all know, but do not sufficiently realize, that it is not exposure to cold alone, but sudden changes, that prove injurious.

Cancer of the Pancreas.

While he does not consider them sufficiently distinctive to warrant a diagnosis, yet Dr. Alois Biach, in *Wiener Med. Presse*, February 11, 1883, gives the following as the symptoms usually observed in cancer of the pancreas:

1. Pain; 2, various dyspeptic disturbances; 3, pancreatic salivation; 4, pancreatic diarrhoea; 5, fatty diarrhoea; 6, the so-called "lipuria;" 7, the presence of a tumor in the epigastrium, which occasionally pulsates; 8, bronze coloration of the skin in occasional cases.

Hypertrophy of Toe Nails.

Before the Midland Medical Society (*Brit. Med. Jour.*, May 12, 1883). Mr. Hugh Thomas exhibited two very long nails, removed from the great toes of a woman aged 65. They had been allowed to remain uncut for eleven years. The right one measured five inches and a quarter, and passed under the four other toes; the left was three inches and three-quarters in length, and lay over the other toes of the foot. The patient was unable to walk. After removal, the matrix on both sides was found to be healthy.

To Prevent Blennorrhoea Neonatorum.

"Immediately after separating the child from its mother it is bathed, and during the bathing the eyelids and their immediate surroundings are carefully cleaned by folds of linen dipped in lukewarm water; afterwards the eyelids are gently separated, and into each eye a drop of a two per cent. solution of nitrate of silver is inserted."

This is Credè's method, and a recent circular from the magistracy of Vienna urges physicians to make its advantages known.

Excision of the Primary Sore in Syphilis.

There seems to be much diversity of opinion upon the merits of this procedure, which is probably due to the difficulty which often obtains in deciding whether certain suspicious sores are specific or not. Prof. Tarnovsky (*Monat. f. Prakt. Dermatol.*), formulates as follows:

1. That the primary syphilitic sore is from the moment of its appearance an evidence of constitutional infection.

2. Usually the wound heals easily after excision, and there is no return of the induration in the place; but there is no change in the course of the constitutional state; and

3. That there is no shortening by this means of the time required in treating the primary sore.

Plaster of Paris Pessary.

Dr. B. F. Dawson uses it. In the *N. Y. Med. Jour.*, May 19, 1883, he describes it. Pledgets of absorbent cotton each with a string attached, are soaked in a mixture of plaster of Paris and water, about the consistence of gum, and partially squeezed out. It is then placed in position. In a few minutes it hardens. It is then burned to remove the cotton, and dipped into wax or paraffine to make it impervious to the secretion. He praises them highly.

The Cause of the Wavy or Interrupted Breath-sound of Incipient Phthisis.

Dr. D. C. McVail (*Brit. Med. Jour.*, May 12, 1883), believes it is due to the transmission of the heart-sound through the solidified lung, since this solidification makes the lung a better conductor. Therefore, when the heart-sound is heard over the apex of a solidified lung, it gives to the ordinary sound of respiration an interrupted character, from the addition to it of this unusual sound.

Odontalgia of Pregnant Women.

M. Lindner strongly recommends the following potion in the dental neuralgia so common in pregnant females, and not caused by dental caries. He has found croton chloral of most benefit, as its analgesic effect persists several days:

R. Croton chloral, gr. xij.
Aq. menth. piperit, ʒj.

M. For one dose. To be taken in wineglassful of wine.

Lumbar Colotomy.

Dr. George R. Fowler reports a successful case of lumbar colotomy in an infant of two months in the *Med. Record*, May 19, 1883. The operation was performed for congenital absence of anus, the fæces having been previously discharged through a recto-vaginal fistula.

Bromide of Gold in Epilepsy.

Bourneville and Magnan have used this drug, in doses of about 10 centigrammes in cases of epilepsy. The results have been negative. Better try the bromide of diamonds.

Loreta's Operation.

The third patient upon whom Prof. Loreta performed his operation of digital division of the pylorus, died of collapse in thirty-six hours. The case was almost hopeless, however, before the operation was begun. The other cases we reported in a previous issue.

Treatment of Gouty Pains and Neuralgia by the External Application of Nitrate of Silver.

Dr. Fronmüller (*Memorabilien*, January 31, 1883) rubs the solid stick over the moistened surface for about thirty seconds. When dry, the skin is covered with a compress of salicylated cotton, which is removed once or twice a day until the blister is healed. In order to be efficient, the irritation should be sufficient to cause an exudation beneath the epidermis.

The Dormant Period of Diphtheria.

A strong appeal for sanitation is made by Mr. John Spear, in his report on an epidemic of diphtheria (*Med. Press*, May 9, 1883), for he clearly shows how the poison of this dread disease has lain dormant in certain localities for months, and again has sprung into activity when favored by bad hygienic surroundings.

Syndectomy for Pannus.

In a paper on this subject by Dr. Flavel B. Tiffany (*St. Louis M. and S. Journal*, May, 1883), the author states that of the twenty-eight times he has made this operation, he has not had a single case where there were any untoward results, and in all but one single exception the results have been most brilliant.

Local Application in Erysipelas of the Face.

The following rather strong application may be painted over the parts affected once every two hours; a thin layer of cotton being placed over the parts immediately afterwards:

R.	Ac. carbolic,	
	Sp. vini Rect, āā	℥j.
	Sp. Terebinth,	℥j.
	Tr. Iodinii,	℥j.
M.	Glycerine.	℥v.

Glycerine.

M. Jaccoud and M. Ferrand are using glycerine in place of cod-liver oil in phthisis, and with such success (*Med. Press*, May 2, 1883) that the former orders it in every case where the oil is not tolerated, and under its use the patients increase in weight, the cough diminishes, and the dyspnoea is in many cases considerably ameliorated.

Depressed Fracture of Skull.

In the *Brit. Med. Jour.*, April 21, 1882, Dr. George Wherry reports the case of a strong man aged 25, with a depressed fracture of the skull, and paralysis, in whom trephining was performed. This was followed by a period of insanity, and subsequently by complete recovery.

The Subcutaneous Injection of Nitro-Glycerine.

A correspondent of the *Medical Times and Gazette* (April 21, 1883,) writes, that by mistake, he injected thirty minims of a one per cent. solution of nitro-glycerine in a case of remittent fever, without any appreciable effects whatsoever. A subsequent examination revealed the presence of nitro-glycerine in the solution.

Chorea.

Dr. C. E. Armand Semple reports in the *Med. Press*, April 18, 1883, two cases of chorea cured by the following formula:

R.—Liquoris arsenicalis, ℥iij;
Mistura ferri perchloridi, ℥ij. Ter die.

CORRESPONDENCE.

Critical Notes on Eclampsia.

EDS. MED. AND SURG. REPORTER:—

It was with mingled feelings of pleasure and regret, that I read the axioms of Dr. Burdett (*REPORTER*, 10th March, 1883).

His first axiom is most excellent, when fully carried out. But bleeding, to be effectual in eclampsia, must be done for effect—to relieve the brain of pressure, to unload the lungs, and to enable the heart to carry its burden. Thus, and thus only, does it become “an anchor of safety.”

The three remaining axioms seem to merge into one—*immediate and unconditional forced delivery*, with the no less exceptional promise annexed, “That delivery will end the convulsions in half an hour.”

I shudder when I read this recommendation, strengthened by adding, “Often, with all the force of traction the attendant could give.”

In the case cited, Dr. Burdett says, “There were fourteen convulsions, six after bleeding to ℥xviii.; only one after loss of consciousness.” If it required thirteen fits to take away consciousness, we may safely infer that they were very light ones; that if the bleeding had been done axiomatically, or had been repeated after the next fit, the eclampsia would have been relieved, and gestation permitted to go on.

Then again, only a few pages further on (31st of March, 1883), we have quite a different solution offered for this difficult problem, by Dr. Fuller: “Addie, primipara, had five convulsions, the severest I ever saw; pulse full and bounding, face flushed; had had excruciating pain in the head—with no sign of labor. I gave

“Fl. ext. veratrum viride, gtt. iv.

“The pain left the head for the uterus, the pulse became softer, the convulsions ceased, and she was delivered in six and a half hours; mother and child doing well.”

We need not question the statement of Dr. Fuller. Similar results have been witnessed by others, where not even four drops of veratria had been used. But we may, and do, protest against the report of solitary, isolated facts and cases, in

a way to mislead and disappoint the young and inexperienced. Those of riper experience will not be misled by them.

E. MICHENER, M. D.

Sylvania, Pa.

A Monstrosity.

EDS. MED. AND SURG. REPORTER:—

On the 6th inst., a male child was born of Mrs. Jacob Baltz, of this vicinity, with the following monstrous peculiarities: There is no external opening to the rectum, and not even an indication in the appearance of the integuments where the anus should be. The contents of the bowels are discharged through the urethra several times through the day, and possess all the qualities of the feces of an infant of its age. Gas also escapes through the same avenue, with a whistling noise, having the sulphuretted odor, showing its source to be in the alimentary canal. The prepuce is defective, covering less than half of the glans. The raphe is drawn up abnormally, by which the testicles are strangely pendant. The veins distributed over the abdomen, together with the integuments, present a bluish tint. There are no other anatomical imperfections.

The child nurses, and has been ordinarily nourished, though not so well developed as it should be at twenty-three days. It is also fretful, and cries a great deal. When the feces pass there is much straining, and apparent tenesmus. There are two other children in the family, a boy and a girl. They are both healthy and well formed, with the exception of the right side of the head, which in both is manifestly larger than the left in all the features, especially the ears.

The parents are Germans, and are both large, healthy and well-formed persons.

T. F. TURNER, M. D.,

Lancaster, Ohio, May 31, 1883.

NEWS AND MISCELLANY.

American Laryngological Association.

(Continued from page 619.)

THIRD DAY.

Dr. J. Solis Cohen, of Philadelphia, read a paper entitled

A CASE OF THYROTOMY FOR MORBID GROWTH; WITH
SUBSEQUENT DEVELOPMENT OF EPITHELIOMA IN
THE CUTANEOUS CICATRIX, BUT WITHOUT
INVOLVEMENT OF THE INTERIOR OF
THE LARYNX.

He was followed by Dr. F. H. Hooper, of Boston, whose paper was entitled

EXPERIMENTAL RESEARCHES ON THE TENSION OF THE
VOCAL BANDS.

Dr. Beverly Robinson, of New York, then read a paper on

AURAL COMPLICATIONS OF INFLAMMATORY CONDITIONS
OF THE NOSE AND THROAT.

The author of the paper believed it was very important for laryngologists to be familiar with the aural complications incident to the disease of

the naso-pharyngeal space, and first directed attention to aural complications accompanying *acute* nasal and throat disease of inflammatory character; and, second, to the aural complications accompanying *chronic* inflammatory conditions of the nose and throat. The aural complications, such as occurred in connection with scarlet fever, diphtheria, measles, typhoid fever, and other acute general diseases and febrile affections, were discussed at considerable length. The author believed the complications were due not, as a rule, to direct extension from the nose and throat through the Eustachian tube to the ear, but to the same cause which produced the general disease. He believed that disease of the middle ear was much more likely to occur as a complication in case of chronic inflammatory affection of the throat and nose than in those cases in which these diseases were not present. In conclusion he urged upon laryngologists the importance of guiding their patients, especially with reference to the hygiene of the ear.

Dr. B. Bryson Delavan then read a paper on

TWO POINTS IN THE ANATOMY OF THE LACUNÆ TONSILLARUM.

Dr. George W. Major, of Montreal, read a paper on

THE VALUE OF POST-LARYNGEAL PAPILLOMATA AS A
MEANS OF DIAGNOSIS IN TUBERCULAR DISEASE.

He held that although these growths were recognized as present in a number of cases of laryngeal phthisis, no special importance as a means of diagnosis or prognosis has been attached to them. It was a difficult matter to say accurately in what proportion of cases of tubercle these developments were to be found, as frequently before coming under observation—laryngoscopically—the cases had either advanced to ulcerative changes, or undergone some local treatment modifying the condition of the facts. He thought about twenty per cent. of the cases might be a safe estimate. In his experience *feathery* papillomata occurring in the region stated were as valuable a means of diagnosing at a very early stage, and before physical signs had been developed, as any before the notice of the profession. Why this should be, he did not pretend to say, any more than he would attempt to explain the proneness of other parts to first affection. The *velvety* growths he did not regard as of paramount value, but considered they should be carefully pronounced upon.

In his private practice, and in the Montreal General Hospital clinique, he had found the conditions referred to, to be a most valuable aid to diagnosis, when present, and had observed the rapidity with which tuberculosis extended in this class of cases.

Dr. E. C. Morgan, of Washington, D. C., reported a case of a large pedunculated myxo-sarcoma, originating from the left glosso-epiglottic fossa and a portion of the lateral pharyngeal wall, in which he was enabled to remove the tumor in rather a novel and primitive manner, viz., by getting its pedicle between the tips of the *index* and *middle fingers*, and using considerable *torsion* and *force*.

The patient, a strong, well-developed man, of forty-nine years, had long suffered from dyspnoea,

dysphagia, and aphonia, which symptoms ceased almost immediately after the extraction. The tumor measured two and one-half inches in lesser, and two and three-quarter inches in greater circumference, was ovoid, of firm consistence, and had a pedicle one quarter inch long.

The common opinion that purely pharyngeal tumors are rare, he thought was erroneous, because he had found sixty-one reported cases, extending over a period of seventy-one years. He included in this class only those tumors which originated within the pharynx or extended into the inferior pharynx. Of the sixty-one cases fourteen were sarcomata and ten fibromata. The interest in his case centered in the rarity of pedunculated sarcomata in this region, the size of the tumor, and the method of removal.

Dr. M. J. Asch, of New York, then reported a case of sudden death occurring after tracheotomy.

At the autopsy nothing was found to account for the sudden death.

Dr. Asch believed that in the majority of cases in which there is obstruction in the larynx, tracheotomy is an exceedingly difficult operation; and that when it is performed for obstruction, whether acute or chronic, however easy its performance might be, tracheotomy should not be viewed in any light except that of a serious surgical procedure.

The reading of papers closed with one by Dr. Andrew H. Smith, of New York, on

ADHESION OF THE VELUM TO THE WALLS OF THE PHARYNX.

The Association then elected as officers for the ensuing year:

President—Dr. Frank H. Bosworth, of New York.

First Vice President—Dr. S. W. Langmaid, of Boston.

Second Vice President—Dr. S. Johnston, of Baltimore.

Member of the Council—Dr. Beverley Robinson, of New York.

Librarian—Dr. T. R. French, of Brooklyn.

The two retiring Vice Presidents, Dr. C. Seiler, of Philadelphia, and Dr. E. F. Ingals, of Chicago, as a committee, conducted the President-elect to the platform, and Dr. Lefferts, in a few well-chosen words, retired from the office, the duties of which he has so satisfactorily discharged. The President made a few appropriate remarks, and then declared the Association adjourned, to meet in New York on the third Monday in May, 1884.

American Surgical Association.

The American Surgical Association convened in its fourth annual session in Cincinnati on Thursday, May 31. There were about sixty members present. The President, Dr. Samuel D. Gross, of Philadelphia, called the meeting to order, and then delivered the following opening address:

FELLOW-MEMBERS OF THE AMERICAN SURGICAL ASSOCIATION: Allow me, as your presiding officer, to congratulate you upon your safe arrival, and to extend to you a cordial welcome to the Queen City, the centre of medical education in the Buckeye State, the residence of eminent medical teachers and practitioners, and the repository of the ashes of great medical men, who, during their

laborious lives, added lustre to the profession, and left behind them undying names. We have come here, not as pleasure-seekers, but as members of a great body of men bent upon earnest work in the interests of our great and noble calling. It is a source of rejoicing to me, as I am sure it is to you, that since our last meeting our ranks have not been invaded by the fell destroyer. On that occasion it was my melancholy duty to announce to you the demise of four of our fellows, all men of distinction and of great usefulness. The meeting upon which we are about to enter cannot fail, if we may judge from our programme, to be of unusual interest, and that our deliberations will be conducted with that celerity and harmony of feeling which has heretofore characterized it, I am safe in predicting. Allow me, in concluding this brief salutatory, to direct your attention to a proposed alteration of the constitution, to increase the number of fellows from 100 to 150. The change is an important one, and merits your serious consideration. I also respectfully suggest that the acting Council be increased from four to seven, so as to impart greater efficiency to its work. Finally, it appears to me wise to take action upon any proposed amendments to the constitution and by-laws on the last day of every session, instead of letting them lie over for one year, as now provided for.

A letter was read from Professor Willard Puck, of New York, in which he regretted his inability to be present, and recommended that future sessions be held in Washington City, so that members might have access to the libraries and museums there located.

The first paper was read by C. B. Nancrede, M. D., of Philadelphia, on the subject, "Have we any therapeutic means, as proved by experiment, which directly affect the local processes of inflammation?"

He was followed by B. A. Watson, M. D., of Jersey City, whose address was on the subject of "Lister's system of antiseptic wound treatment, versus its modifications."

At the conclusion of the last named paper the meeting adjourned and reassembled at three o'clock in the afternoon, when Dr. John H. Packard, of Philadelphia, read an interesting paper on the somewhat elaborate subject, "Reamputation of the hip-joint. Secondary Hæmorrhage. Ligation of the Primitive Iliac Artery. Remarks on Ligations."

The paper was discussed at length by Drs. Henry T. Campbell, of Augusta, Ga.; David M. Cheever, of Boston, and P. S. Conner, of the city.

Dr. Basil Norris, of the United States Army, was to have read a paper on the "Dislocation of the Astragalus," but at the last moment telegraphed that he could not be present in time to fulfill the duty. The vacancy was most acceptably filled by Dr. T. G. Richardson, of New Orleans, who read an instructive paper devoted to a discussion of a peculiar aneurismal formation of the thigh. He likewise read reports of several cases of excision of the ribs and trephining of the same for pus cavities in the thorax. The report was discussed by Prof. Gross.

The meeting then adjourned to the dissecting-room of the Ohio Medical College, under the care of Dr. P. S. Conner, where Dr. Packard demon-

strated on the cadaver the feasibility of the operations described in his paper. He also illustrated by the same medium his new method of reaching the colon by an incision through the back, in cases of obstruction or other troubles in that organ.

The session was then adjourned to meet the next morning at ten o'clock. In the evening a banquet was tendered the visiting physicians at the Gibson House. At the head of the long table, which was beautifully adorned with beds of flowers and baskets of fruits, sat Dr. S. D. Gross, the head and front of American surgeons, and on either side were seated men whose operations in surgery have made them famous. The occasion was a delightfully informal one, and there was an absence of regular toasts which was an agreeable innovation upon the average banquet.

The Association reassembled on Friday morning with a much larger attendance than on the preceding day.

In the absence of Dr. J. W. Yandell, of Louisville, who had been announced to read a paper on the subject "Resection of the Ribs," Dr. Gross delivered a discursive and interesting address on the value of early and late experiments in surgery. He was followed by Dr. Basil Norris, U. S. A., with an elaborate paper on "Dislocation of the Astralagus." At the conclusion the paper was liberally discussed by Dr. Gross and others. He was followed by Dr. P. S. Conner, who treated the subject, "Excisions of the Tarsus," in his usual masterly and thorough manner. Dr. L. A. Sayre, of New York, being absent from the session, his paper was omitted, and Dr. Marks, of Milwaukee, discoursed upon the method of "Trephining the Sternum for Removing Foreign Bodies from the Anterior Mediastinum."

At the afternoon session, Dr. E. M. Moore, of Rochester, N. Y., read a paper founded upon "Some Questions with Reference to Intra-Capsular Fracture of the Femur." The most elaborate paper of the entire session, possibly, was read later by Dr. M. Sern, of Milwaukee, regarding "Fractures of the Neck of the Femur, with Special Reference to Bony Union after Intra-Capsular Fracture." He illustrated by specimens as he proceeded. The paper, which was read for the most part by subjects, was discussed at length, after which the body adjourned.

In the evening Drs. N. P. Dandridge, of Cincinnati; Chris. Senger, of Chicago, Ill.; W. E. Taylor, of California; W. F. Peck, of Davenport, Iowa; and McCann, of Pittsburgh, were elected members of the Association.

(To be Concluded.)

Ship Surgeons.

A committee of the British Medical Association are petitioning the Board of Trade to reform, or rather to inaugurate, a system of Marine Medical service, in connection with which Dr. J. A. Irwin makes the following lamentable statement, of dreary interest to all contemplating its disastrous effects:

Not less than 140 medical officers, approved by the emigration officer at the port of clearance, were intrusted, on different voyages, with the sole "medical charge" of 108 steamships, which,

during the six months ending June 30, 1882, carried emigrants from Great Britain to the United States and Canada. Of these gentlemen, 8 possessed no qualification which would entitle them to practice in the United Kingdom; while, of 132 remaining, 35 held but a single diploma—29 as surgeon alone, 3 as physician alone, and three as apothecary alone. Forty-six are reported as being twenty-five years of age or under, and 19 as being twenty-three years of age or under. Of the latter, 11 possessed but a single qualification. Of these 132 medical officers, but twenty-four possessing any qualifications as a physician and surgeon, had reached their thirtieth year. Such facts need no comment. Certainly they go far to prove—there being nothing exceptional during the period named—that these officers "are appointed without due regard to age, qualification, or experience;" and that "comparatively few medical officers in every way suitable can be found in the mercantile marine medical service."

The Poison of the Coral Snake.

According to a detailed account given by Mr. F. W. True (*American Naturalist*, January, 1883) the coral snake of the Gulf States (*Elaps fulvius*) is poisonous, and the only reasons that injuries from it are rare, are (1) the scarcity of the snakes in the neighborhood of towns, (2) their sluggish disposition, and (3) the small size of the mouth. The snake, which occurs in southwestern Texas, Florida and Mexico, ranges from twelve to twenty-four or thirty inches in length. Mr. Shindler, an artist in the United States National Museum, was bitten by one that he was sketching, and in spite of cauterization was sick for two or three days, but recovered his health under prompt medical treatment.

Dr. Kearney, of San Antonio, Texas, mentions a case in which death followed the bite, but the victim was a child.

The deadly cobra of India, from whose bite more than 18,000 persons perish annually, and the asp of North Africa, belong to the same family (*Elapidae*) with the coral snake.

An Objection to the Electric Light.

Dr. Morris recently read a paper before the Birmingham Philosophical Society, entitled, "Experiments and Observations on the Air of the Birmingham Town Hall." He gave particulars of the results of his investigations as to the temperature and composition of the air in the hall when the building was lighted by gas, and also when lighted by electricity. His conclusion was, that the lighting of the public buildings by the electric light did not possess such superiority in ordinary cases over lighting by gas as might have been expected. That, he thought, was due to the fact that gas assisted in the ventilation by producing upward currents, which dragged up the lower strata of polluted air, whilst the electric light in no respect assisted ventilation.

Artificial Coffee.

The *Chemist and Druggist*, February 15, 1883, says that Sornani, of Pavia, in the *Ann. di Chin. Appl. Farm. ed Med.*, announces that he has discovered

ered quite a new and serious adulteration of coffee which is being practiced by the manufacture of artificial berries. These berries are composed of the meal of beans and acorns, with chicory and quartz powder to bring the mixture to the requisite specific gravity. A dough is made of these ingredients, which is cut by a special machine into the shape of coffee berries, and after drying, has exactly their color. Sornani says he has found as much as fifty per cent. of these artificial berries mixed with the genuine. On roasting, they take just the same color as the genuine, but they are discovered by soaking in water, when the false berries soon fall to pieces.

A Root Doctor.

A St. Louis doctor asserts that an old fellow living on the State line, who claims to be a root doctor, has had three medicines in the dispensatory. He names them respectively Hibobalorum, Lobobahirum, and Hilobustem. One is a cathartic, another an emetic, and the last a "rank pizen," which will bust his patients open. He makes the first by peeling the bark downward, the second by peeling it upward, and the last by peeling it around.

The Capon Springs.

This thermal and mineral source has long enjoyed a reputation as one of the most active of the therapeutic waters of West Virginia. The locality is an exceptionally healthy one; and we are informed that the accommodations for visitors are quite satisfactory.

The Berlin Polyclinic.

This institution, situated 51 Louisen Strasse, Berlin, merits the attention of all physicians who pay a visit to that great capital. Regular lectures on all the specialties are delivered, each course beginning on the first of a month and lasting through the month.

Items.

—Seventeen medical men have been chosen members of the Italian Parliament at the last general election.

—Dr. T. Lawrie Gentles, of England, has performed a successful operation for strangulated hernia in a man aged 86.

—In the *Brit. Med. Jour.*, April 28, 1883, Mr. Walsham reports a case of excision of cancer of the rectum with recovery.

—*Lycopodium* can be put to an excellent use when sprinkled over oiled silk. It prevents the fabric from adhering together.

—The managers of the Garfield Memorial Hospital have purchased a piece of property situated in the suburbs of Washington at a cost of \$37,000.

—On the reassembling of the French Chambers, the Government intend submitting a bill to raise Dr. Pasteur's yearly pension from 12,000 to 25,000 francs.

—The French law decrees that the legitimacy of a child born three hundred days after the death

or departure of the husband need not necessarily be questioned.

—A doctor is a *pillar* of society. His enemies say that he can kill with *powder* without shot, and that his *drops* are almost as dangerous as the hangman's.

—A hospital for the children of gentlemen of limited means—a class believed to be increasing both in number and necessity—has been established in England.

—Wave-lengths of the sounds emitted by a man's voice in ordinary conversation are from eight feet to twelve feet, and of women's, two feet to four feet per second.

—The Emperor of China has received the permission of the Government of India to send a certain number of youths to India, with a view to their studying European medicine and surgery at the Medical Colleges.

—Sir William Thomson follows Dr. Thomas Reed in ascribing to man six senses instead of five, namely, the sense of force, of heat, of sound, of light, of taste, and of smell.

—The number of students in the medical faculty of the University of Vienna during the session recently ended was 1,750, against 1,412 in the corresponding period of last year.

—Dr. Truzzi vaccinated a number of pregnant women during the last three months of gestation, with a view to determine the protection, if any, afforded to the child. The results were negative, as the children were all successfully vaccinated a few days after birth.

—In the new German Pharmacopœia, 360 articles have been struck out, and 48 added, a decrease of 312, the whole number being about 600. In the new edition of the U. S. Pharmacopœia 229 articles were cut out and 256 added, a net increase of 27, the whole number being 1,000.

—After a recent violent storm on the English coast, a quantity of saline matter was observed on windows at a distance inland. The deposit is believed to have been made by ocean spray, which in this case must have been blown by the wind at least sixty miles.

—On the announcement in Russia that the course of medical instruction for women would be closed, a great meeting was held to protest against the measure, and a Moscow merchant offered to spend 200,000 roubles if the St. Petersburg authorities would undertake the management of the lectures.

MARRIAGES.

HAIR—MORTON.—On May 22, 1883, by Rev. W. C. Falconer, D. D., of Springfield, Ohio, Dr. B. W. Hair and Mrs. M. M. Morton. All of Cincinnati, Ohio.

DEATHS.

FISHER.—On May 30, Dr. Joseph M. Fisher, in the fifty-fourth year of his age.

BRUNS.—In New Orleans, suddenly, May 20, 1883, Dr. J. Dickinson Bruns, aged fifty years.

COMMUNICATIONS.

IS THE CURRENT THEORY THAT TYPHOID FEVER OWES ITS ORIGIN TO SEWER-GAS EXPLODED? AND IS THE GREATER FA- TALITY OF TYPHOID FEVER IN THE COUNTRY CAUSED BY GREATER IM- PURITY OF THE DRINKING-WATER COMPARED WITH THAT OF THE CITY?

BY DR. GEORGE HAMILTON,
Of Philadelphia.

In the discussion subsequent to the reading of a paper upon this subject before the College of Physicians, March 7, by the writer, not a little surprise must have been felt at the declaration by the pre-eminent sanitary engineer, George E. Waring, "that the sewer-gas theory in regard to typhoid fever was, in the opinion of sanitarians, exploded." This announcement is the more remarkable and important, standing, as it does, in antagonism to the teaching and recommendations of many professed sanitary engineers, "that every effort should be made to exclude sewer-gas from dwellings, regarding it as the general, if not the sole cause, not only of typhoid, but also of scarlet fever and diphtheria." Neither does this doctrine, nor do these recommendations, run counter to the opinions, nor fail to obtain the support, of a large majority of physicians. Many of the medical journals, and not a few professors, coincide in this view, and successfully impress its alleged correctness upon the mind of the inexperienced student and young practitioner. Quite recently there appeared in a medical journal a

paragraph, contributed by a somewhat conspicuous physician, to this effect: "Is it not surprising and incomprehensible that there can yet be found physicians who deny the agency of sewer-gas in causing typhoid fever, diphtheria, and scarlet fever?" When it is stated that the writer of this quotation was, and continues to be, one of the most zealous and positive in regard to sewer-gas being the effective agent in the production of the diseases just named, may we not imagine an increased degree of surprise when he learns that this pre-eminent sanitary engineer declares "that the sewer-gas theory is, in the opinion of sanitarians, exploded!"

The paper upon Sewer Gas, by Dr. Frank Hamilton, published some months ago in the *Popular Science Monthly*, with its numerous quotations, cannot be construed in opposition to the opinions heretofore, and at the present time, held by physicians, sanitarians, and the public generally. The special object of that paper was, in fact, to devise more certain and reliable measures to exclude from dwellings this alleged source of disease; and to accomplish this, as was believed, desirable and well-intentioned object, scientific plumbing and improved apparatus, erected in an annex outside of the residence, were recommended. The efforts to exclude the gas are, up to the present moment, incessant; nor is this surprising in view of what has just been stated. Whether the typhoid, the scarlatinal or the diphtheritic germ, or some special quality of the gas itself, dependent upon peculiar matters finding entrance to the sewers, and subjected to various degrees of warmth and moisture, be the deleterious agents in question, is immaterial; for, practically,

to admit the gas, is to admit one or other of these agents—to exclude the gas, is to exclude them. Attempts to diminish the importance of sewer-gas as the chief agent in causing typhoid fever and other affections are manifest enough, and efforts in this direction are doubtlessly made by those who candidly acknowledge that the reports of the Board of Health of this city, and those of New York, are in opposition thereto. But this is not all, for a very large proportion of those physicians who have had the most frequent and abundant opportunities to observe the origin, development, and progress of typhoid fever, either withhold their assent from the current views upon this subject, or positively deny that sewer-gas is the sole cause of typhoid fever, or that it exceeds all other agencies combined in originating this disease. Does it not seem passing strange in this connection, that while the Trousseaus, the Niemeyers, the Murchisons, the Bristowes, the Flints, the Jacksons, and many others of similar experience and capacity, entertain doubts in reference to certain points pertaining to the origin and progress of typhoid fever, and express their opinions in relation thereto with calm, philosophic, commendable reserve, very many others, of different qualifications and temperament, find no difficulty of this kind, but, on the contrary, armed *cap-à-pie*, are always ready to solve any question in regard to this subject. Unfortunately, these attempted solutions are too often merely bold, positive assertions, having no real basis of support, and this is seen in the statement by some, “that the families located in the wealthy and fashionable parts of Philadelphia and New York are most liable to attacks of typhoid fever,” while the Reports of the Board of Health of both cities show, on the contrary, that the suburbs exhibit by far the largest number of cases. This accords perfectly with the testimony of the late Prof. John K. Mitchell, alluded to in my paper of the 7th of March, who, in consultation, told the writer and the late Dr. Louis P. Gebhard, “that he seldom saw cases of typhoid fever except on the outskirts of the city, where water-closets were scarcely known.”

One of the great difficulties with the sanguine theorist is in relation to the greater prevalence and fatality of this disease in the country. But, as usual, the explanation is at hand in the fact, as he boldly asserts, that the drinking water is contaminated by the drainage from the necessary. Now, this assertion should, if believed, inspire far more dread than the sewer-gas theory ever did, even in its palmiest days, long before the recent decree that it had been exploded was an-

nounced. What must now be the state of mind of the laborious farmer and family, in reflecting that to his own negligence or stupidity is he indebted for this sad condition of his household? But the mischief does not end here; for what, it may be rationally be asked, is to become of the thousands upon thousands of our citizens who every summer gladly visit the country and seek boarding with the farmer, or select, for a season, the accommodations furnished by cottages or hotels; many of them for the express purpose of escaping, as they declare, the heated and impure air of the city, and the contaminated water of the Schuylkill, receiving constantly, as it is stated, an immense amount of impurity from Manayunk, and many other points nearer to Fairmount! As is well known, not a few of the country people, on visiting the city, alarmed by the exaggerated reports of the condition of the water, abstain, as far as possible, from its use. But admitting the supposition, for it is nothing more, to be true, as to the contamination of the water in the notably beautiful, rolling country of the counties around Philadelphia, how are we to explain the fact that at uncertain intervals a severe epidemic will suddenly appear—fever sometimes, dysentery at other times—and will just as suddenly disappear, and neither of these diseases again be seen, to any extent, for one or several years, precisely as has often occurred in this city, and elsewhere. To suppose that the water has thus suddenly changed from purity to impurity, and again as suddenly to purity, with no conceivable cause, either by the family or the medical attendant, is simply absurd.

Such a statement as was made in the discussion alluded to as to the condition of what were termed country towns in New England can have but limited application, and is completely at variance with the contents of a letter from a conspicuous physician in one of the New England States, who, after inquiry in regard to outbreaks of typhoid fever, had replies from about fifty practitioners in that State to this effect, that the rural sections suffered by far the most from epidemics of typhoid fever. Any one who has traveled over the rural sections of New England could not have failed to observe the generally excellent condition of the farms, whatever he may have noticed of a contrary character in some localities. But why go from our own city or vicinity? Have we not in this city, or within an hour's journey, numerous factories and densely peopled districts notorious, when compared with the country, for their filthiness, with cess-pools and innumerable privies almost in contact with dwellings, and, in many

cases, in consequence of the porous nature of the soil, filled to repletion, affording every opportunity for contamination of the water in comparison with the country?

To show how delusive plausibly-written accounts of the origin and spread of typhoid fever may be, let the following suffice: A woman, after nursing a relative during several weeks, returned, after the death of the patient, to her own residence, distant three miles. In a few days she was prostrated with typhoid fever—the disease of the relative. In succession, one after another was attacked, until four out of seven members of the family were down with the disease, one death ensuing from perforation.

In the discussion of the paper, one of those who had taken part thought there could be no difficulty in accounting for the attacks of the last three members, as the dejections from the bowels of the woman were cast out in such a way as to admit of drainage into the drinking-water, and that thus the typhoid germs were received into the stomachs of those last attacked. But, unfortunately for this solution, the drainage descended the slope from the source of the water to the requisite outhouse.

In another family of eight persons, quoted in the lecture of March 7th, seven were attacked with the fever, all of which, except a colored servant, were dangerous cases. As in the former instance, the disease did not originate upon the premises. A son had been sent about forty miles into Maryland, and after remaining there several weeks, was brought home sick with typhoid fever, and in succession six other members were prostrated with the same disease. The house was upon a hillside, and, as in the former case, the drainage was from the water in the direction of the outhouse, so that contamination of the water in either instance was impossible. Typhoid fever, scarlet fever, diphtheria and dysentery, may not, under certain favorable conditions, be contagious; but under other conditions, as when these diseases are malignant, and the subjects crowded together, for example, three in the same room, as occurred in the family just alluded to, they are regarded by an immense majority of the most able, unprejudiced, and experienced physicians, as eminently contagious.

Col. Waring, to his credit be it said, was commendably conservative in this discussion, not disposed to be dogmatic, and in regard to this special point merely said that "The literature of the subject *seems* to prove that typhoid fever, in the country, is due to drinking water which has become contaminated," knowing, doubtless, full

well, that a score of probabilities can avail nothing when confronted by a single irrefutable fact. To revert for a moment to sewer-gas, it appears, from the remarks of one of the disputants, to be now placed in a worse position than ever; for while it is admitted to be the *vehicle for conveying typhoid germs*, when it contains them (?) it is also declared to be "the most potent cause of the typhoid state." The importance of this statement will at once be appreciated when we call to mind that the typhoid state is the almost invariable concomitant of the latter stages of dangerous and fatal diseases, whether acute or chronic.

During the discussion, repeated appeals were made on behalf of cleanliness. But who ever heard of any one, who had the least regard to the amenities of life, opposed to cleanliness?—for is it not said to be "akin to godliness."

As pertinent to this subject, Dr. John Syer Britton, President of the Society of Medical Officers of Health, confessedly one of the most sagacious observers and logical thinkers of the day, writes as follows: "If we look to the remarkable influence which simple *variations of temperature and peculiarities of season* exert on the mortality returns, in respect both of the number of deaths and the character of the fatal diseases, and compare therewith the comparatively small effect on the death-rate of even one of the most fatal of the zymotic diseases, or with the insignificant influence of deaths from enteric fever, diphtheria, and other affections, over which *sanitary science is supposed to exert a specially valuable influence*, we can scarcely avoid seeing, that on similar grounds, the deaths saved directly by the sanitary labors on which we are engaged, must, under any circumstances, be so few annually as to produce no *distinct and unmistakable effect on the mortality rates*." This sincere and ingenuous avowal of opinion, by one so distinguished as an author and teacher, may well be commended to the serious consideration of those who, for years past, have boastingly promised the extinction of certain diseases, under certain impossible conditions, yet with no other result than that just presented by the above-named conscientious and distinguished authority in medical science.

VIEWS OF MORTALITY STATISTICS, WITH SPECIAL REFERENCE TO THE U. S. CENSUS RETURNS OF 1880.

BY THOS. S. SOSINSKEY, M. D., PH. D.,
Of Philadelphia.

(Continued from page 627.)

Altogether, then, I believe I have said enough

to show that Dr. Billings assumed a great deal when he ventured the opinion that the greater returns in 1880 than in 1870 were due to a better canvass of deaths.

Passing on a little further in Dr. Billings' introductory remarks, I find that he figures out "an average mortality of the whole country of 18.2 per 1,000 of living population per annum." "The actual mortality," says he, "for the whole country during the census year was not less than 17, nor greater than 19, per 1,000." Now, how did the ingenious Doctor find this out? Finding the difference between the enumerators' returns and the State returns to be as given above, he decided that "it may be considered certain that in no State is the deficiency in the enumerators' returns less than it is in Massachusetts." "If we suppose," says he, "that after the addition of the 61,020 cases of deaths reported by physicians* to the returns of the enumerators, these last, excluding the states and cities above mentioned, are still deficient as much as 30 per cent., which is believed to be the maximum, the result will be an average mortality for the whole country of 18.2 per 1,000 of living population per annum." It is hardly allowable to assume that the percentage of deficiency is about equal in different States, the state of concentration, the intelligence, and other peculiarities of the population, telling on the results. Here is a point of special moment, namely, the amount of mortality among infants. If the deficiency be greatest among infants, as Dr. Billings says it is, the fact that the returns show that the proportion of deaths of infants to those of persons of all ages varies greatly, would indicate a wide range of variation in the deficiency in different States. Thus, as will be shown below, the proportion of deaths of infants to the whole in Pennsylvania was 1 to 4.6, while in Kansas it was 1 to 2.6.

O Libitina, how very ignorant we are as to how many bodies pass into thy hands from year to year in this broad land! Little reliance can be placed in the truth of the conclusions of Dr. Billings. Such conclusions are little better than guesses, whereas there should be no guessing in making up vital statistics, otherwise they are no statistics at all. But what can be thought of the work of enumerators which is likely deficient in general to the extent of a third!

* Blank books were sent out by the Census Bureau to the physicians throughout the United States, in which to enter all deaths occurring in their practice during the census year. The 61,020 cases referred to were found, I understand, to have been omitted by the census enumerators.

In this connection I may remark, that I do not wish to convey the impression that I am of the opinion that the census returns of vital statistics are of no value. I believe they are of much value, giving as they do a vast deal of more or less definite information about the destructiveness of different diseases in different parts of the country, the relations of age, sex, and season to diseases, etc.

Having decided that the death-rate in the United States was somewhere between 17 and 19 per 1000 of the living population, Dr. Billings proceeds with great complaisance to say that "this rate compares favorably with that of all other civilized countries. The death-rate in the rural population of England, comprising ten and a half millions of people, in the year 1880, was 18.5 per 1000. For the whole of England for the same year it was 20.5 per 1000. For Scotland, it was 21.3 per 1000. For the mainland rural group of Scotland, for the same period, it was 17.3 per 1000."

This is distressing. I wonder when it will be generally known that comparing aggregate rates of mortality of different places is entirely unscientific and absurd. It is an error of a preposterous kind, one that the merest tyro should not commit. Especially is it absurd to compare the death-rates of long-settled, comparatively stable communities, with those of places of a reverse character. The only proper comparison of an aggregate rate of mortality is with the rate in the same place in preceding years; and this is not of much interest, or practical value, unless a detailed analysis of the causes of death, and the period of life at which they occurred, be made.

The period of life at which the deaths occurred is a very important point to know in considering death-rates, and especially if one would institute comparisons. There may be a great disproportion in the number of people of different ages who die in different places. A very large proportion may be of persons past middle life in one place, while the reverse may be the case in another. During the census year ending June 1, 1880, of the deaths returned, the proportion of those of persons under one year to the whole in Massachusetts was 1 to 4.5; in Illinois, 1 to 4.1; in Pennsylvania, 1 to 4.6; in Georgia, 1 to 3.9, and in Kansas, 1 to 2.6; and the proportion of those of persons under five years to the whole in Massachusetts was 1 to 3; in Illinois, 1 to 2.3; in Pennsylvania, 1 to 2.6; in Georgia, 1 to 2.1; in Kansas, 1 to 2.1. These are somewhat striking figures. It is scarcely necessary to remark that it is particularly lamentable

when there is a heavy mortality among persons in early adult and middle life. The life of a baby is of much less worth than that of a person arrived at maturity. A study of this kind may be pursued profitably from the standpoint of the political economist.

In any community, or country, it would be extremely desirable to know the proportion of deaths among persons of different ages, but such knowledge is not readily attainable in reliable shape. The ages given in the census returns are notoriously unreliable. Thus 1,282,253 were said to be ten; while only 1,256,956 were one year old; and 682,714 were said to be fifty, while only 323,608 were forty-one years old. Without a knowledge of the rate of death among persons of different ages, it is impossible to construct a table of the expectation of life; and as Dr. Parkes says this, that is, the mean future or after life-time, "is the true test of the health of a people." A table of this kind cannot be expected under any circumstances to be very accurate, but more especially for an unstable community.

In a country like ours, to which a vast current of healthy young people is flowing from Europe and elsewhere, the death-rate should not be as high as in the communities whence these came. For evidently when great numbers of the young adults go from a place, the proportion of old, sickly and very young persons is greatly increased, and of course it is among such that the bulk of the mortality occurs everywhere.

The movement of population going on in this country renders comparisons of the aggregate rates of mortality of different parts of it extremely unscientific and misleading.

The birth-rate in the United States is not as high as one might expect. In proportion to the number of marriages it is low, and, indeed, the tendency to check productiveness is growing more and more obvious to every thoughtful observer from year to year. It is far from being alike in all parts. But, altogether, there is great productiveness. This is one and the main reason why a considerable death-rate should be expected in the United States. Calculations show that the births to the population in 1870, according to the census returns, were 1 to 31, and in 1880, 1 to 30. In determining these figures, the deaths of children under one year were added to the number of children under one year living, and this number was taken from the whole population plus the number of deaths.

To illustrate how different the populations of different states are as regards age, I have com-

piled the following table from the statistics of 1880:

STATE.	AGE.				
	Under 2 yrs.	30 years . .	50 years . .	60 years . .	70 years . .
Massachusetts	$\frac{1}{25}$	$\frac{41}{1}$	$\frac{56}{1}$	$\frac{88}{1}$	$\frac{190}{1}$
Michigan	$\frac{20}{1}$	$\frac{50}{1}$	$\frac{88}{1}$	$\frac{145}{1}$	$\frac{324}{1}$
Kansas	$\frac{16}{1}$	$\frac{50}{1}$	$\frac{115}{1}$	$\frac{210}{1}$	$\frac{605}{1}$
Illinois	$\frac{19}{1}$	$\frac{50}{1}$	$\frac{80}{1}$	$\frac{121}{1}$	$\frac{378}{1}$
Pennsylvania	$\frac{20}{1}$	$\frac{50}{1}$	$\frac{78}{1}$	$\frac{147}{1}$	$\frac{268}{1}$
New York	$\frac{24}{1}$	$\frac{43}{1}$	$\frac{58}{1}$	$\frac{90}{1}$	$\frac{209}{1}$
New Jersey	$\frac{21}{1}$	$\frac{45}{1}$	$\frac{63}{1}$	$\frac{102}{1}$	$\frac{238}{1}$

It is evident from this table that the babies are comparatively scarce in Massachusetts. There would seem to be something wrong with the women or with both sexes in that State. With so few infants, there should not be a high death-rate there, unless they are exceptionally degenerate as well as scarce. In Kansas it will be observed that one-sixteenth of the population are of children under two years of age. Evidently, if the babies were not healthy in that thriving State the death-rate should be high.

Massachusetts has a far greater proportion of persons of 30, 50, 60, and 70 years of age than any of the other States in the list. The comparative scarcity of children may account to some extent at least for this remarkable social feature of that State. The great proportion of old people there should tend to make the death-rate high.

As the table shows, $\frac{1}{100}$ of the population of Massachusetts were 70 years of age, while in Kansas the number was only $\frac{1}{605}$. Taking this statement as it stands, one would naturally conclude that the chance of living to be old is far better in Massachusetts than in Kansas. But the statement is misleading. It is akin to the obviously fallacious one that the small number of deaths of female in comparison with those of male Chinese in this country indicates that the former find it far more healthful than the latter. Kansas has comparatively few old people, because the population is, as a whole, of very recent growth. With so few old people, the death-rate should be extremely low, if it were not that the proportion of children (among whom there is always a pretty heavy mortality) is very large.

With apparent fullness of confidence in his philosophy, Dr. Billings remarks that "the low death-rate in this country is considered to be due to the comparative absence of overcrowding, and

to the more general and equable distribution of the means of supporting life, including especially the abundant food supply of good quality for all classes of the people." The Doctor assumes much in regarding the rate given by him as low; I take it to be high. A fresh, enterprising people, and one not disposed to be very prolific, should furnish a low death-rate. Anything above 15 per 1000 is excessive in most parts of the United States, and, indeed, in the country as a whole. Various points made above are confirmatory of the belief that the death-rate should be comparatively low. It is very questionable whether the "abundant food supply" argument of Dr. Billings is very forcible. I am rather inclined to hold that it is the reverse. A population that has little incentive to be frugal is not apt to be freest from disease, and the longest lived. Indulgence too generally attends plenty; and this vice hurries people prematurely into their graves. As Bacon well observed, life is not favored by "luxury and ease."

SULPHUR PREPARATIONS IN ACNE.

BY H. W. STELWAGON, M. D.,

Physician to the Philadelphia Dispensary for Skin Diseases,
Service for Diseases of the Skin, Northern Dispensary,
and Département for Diseases of the Skin, Howard
Hospital.

Sulphur, as a local application in the treatment of acne, has survived the deluge of new remedies; and although at times pushed momentarily to the background, it stands to-day the most reliable therapeutical agent for this affection. It has been employed in all of its various chemical preparations, and is so used at the present time. All are useful, and each has its advocates. Experience in their use, however, soon narrows the choice to a limited few. The most trustworthy of the preparations are the simple sulphur, either as the washed sulphur, precipitated sulphur, or flowers of sulphur, and sulphuret of potassium. There is very little difference in the varieties, so to speak, of plain sulphur, although preference is usually given to the precipitated. These two preparations, sulphur and the sulphuret of potassium, are not only the most valuable in their therapeutical effects, but also the cheapest—a small matter, it is true, yet of some importance. The plain sulphur may be used in various ways. In mild cases it may be employed simply as a toilet powder, and so used is frequently of advantage. As such, it should be dusted on the face at night by means of a powder brush and allowed to remain undisturbed until morning. The plan

is easy to carry out, and for that reason commends itself. It is, as a rule, less efficient than lotions or ointments, inasmuch as it is less intimately brought in contact with the skin. In the form of a lotion sulphur is often of great service. No better formula can be given than that containing a small amount of glycerine—ten minims to the ounce—and equal parts of alcohol and rose water. A combination, suggested by Dr. Bulkley, of a drachm of washed sulphur, a half fluid ounce of ether and three and a half fluid ounces of alcohol makes an excellent application, and is especially indicated in those cases in which comedones are predominant, or in which there is a moderate degree of seborrhœa present. Kummerfeld's lotion is another very useful combination:

R.	Sulph. præcip.,	℥iv.
	Pulv. camphoræ,	gr. x.
	Pulv. tragacanth,	gr. xx.
	Aquæ calcis,	
	Aquæ rosæ,	āā f. ℥ij.

M.

The proportion of sulphur in lotions should depend upon the effect produced, or to be produced; ten grains to a drachm or more to the ounce. A scruple to the ounce is a proportion most commonly used. Sulphur in ointment is another method in which this remedy may be advantageously employed. In the strength of one drachm to the ounce it is a very useful application. The percentage of sulphur in ointments is usually greater than in lotions, varying from twenty grains to the ounce up to equal parts.

The sulphuret of potassium, the other sulphur preparation which stands high in the treatment of acne, is, I think, superior to the simple sulphur, although it is not in such general use. This may be due to the fact that sulphur itself has been always used and considered "good for skin diseases," while the employment of the sulphuret of potassium is more recent and the knowledge of its application less wide-spread. The sulphuretted odor of the drug is a disadvantage, but it admits of correction if desired; besides, even in its undisguised condition, the odor is merely concomitant with the application, as a few minutes afterward it is scarcely noticeable.

It may be employed either as a lotion or as an ointment. The strength varies from five grains up to a half drachm to the ounce. The proportion which is most generally required is about fifteen grains to the ounce. The lotion may consist of a simple watery solution, or small quantities of alcohol and glycerine may be added at times with advantage; the former a half drachm to the ounce, and the latter about ten minims to

the ounce. The efficacy of such a lotion is in some instances increased by adding to it sulphate of zinc in the same proportion as the sulphuret of potassium.

An ointment may be ordered instead of a lotion, and is, occasionally, of greater service. The lotion, however, is less tenacious of its odor, and, on the whole, is probably more efficacious.

In the use of sulphur itself, preference is generally given to the ointment method; the sulphuret of potassium, on the contrary, is usually prescribed as a wash. In neither case is there any substantial reason for this, and it seems due merely to force of example or habit. It is a fact worth remembering that in some instances lotions prove of value where ointments had failed to benefit; the converse of this also holds true. Moreover, in some cases, sulphur itself may produce but little improvement, whereas marked advantage is found to follow a change to sulphuret of potassium, and *vice versa*.

The applications are best made at bed-time, as they are then less apt to be disturbed, and may remain on over night, and are moreover more comfortable and convenient for the patient.

Before applying the preparation, the face should be sponged with hot water for several minutes. The ointment then, if that is used, should be well rubbed in, and not disturbed until morning, when the face may be washed. If the lotion is employed, it should be well shaken, and rubbed on with a sponge or rag for three or four minutes, and allowed to dry and remain undisturbed until the face is washed the next morning.

It is well to intermit treatment every week for a few days in order that the furfuraceous desquamation which all such preparations are apt to produce, although slight and scarcely noticeable, may disappear. In this respect the ointments are far less objectionable, as the unguent, in a measure, prevents or conceals it.

The above preparations or combinations used in the manner described are, as I have repeatedly seen, productive of great benefit in cases of this disease: and conjoined with appropriate constitutional treatment, and perseveringly used, are in a fair proportion of the cases curative.

THE ABORTIVE TREATMENT OF VARIOLA.

BY W. R. CLARIDGE, M. D.,
Of Philadelphia, Pa.

The *Southern Clinic* of last year contained a contribution from the pen of Dr. DeCailhol, of St. Louis, Mo., styled, "Variola—its treatment, its

prophylaxis," in the reading of which I was much interested, although unable to agree with the writer in his views respecting the inutility of vaccination. It was with what he styles the French abortive treatment I felt most interest. The Doctor states that during his last sojourn in Paris Dr. Mene, connected with one of the children's hospitals of that city, explained to him the benefit of his (Dr. M.'s) abortive treatment of variola, and that since his return to the United States he has tested its efficacy frequently, and has recommended it to many of his brother practitioners with satisfactory results. This was the use of salicylic acid.

Having been practicing medicine between twenty and thirty years, I have had during that time hundreds of cases of variola to treat, the disgusting character of which, together with the often unsatisfactory results, made me wish for some better methods of treatment than that usually resorted to, and desirous of trying this to me new remedy.

It was not until April last that I had an opportunity of testing its action, when I was sent for to see Mr. W—, aged 74 years. I found him literally covered with variolous eruptions in the vesicular stage, and, commencing to umbilicate. He had up to this time ordinary good health, but was somewhat enfeebled by age.

To prevent injury through fear, it was thought best to conceal from him his true condition, and he was led to believe he was suffering from *nettle-rash*, and was not aware of the reality until well, so that on one occasion of my visit he said to me: "Doctor, I think I once had a horse that had the same disease I have," and then went on to describe the condition of the animal. I need not say we were amused. I immediately commenced the giving of salicylic acid in doses of ten grains. It was given regularly every three hours, day and night, in a liquid form combined with mucilage.

On the third day of its administration the pustules began to abort, their contents absorbed gradually, leaving a *pale, thin scab*, or scale, much resembling a minute fish-scale. These scales separated so rapidly that large quantities were removed each morning when changing the bed linen.

In two weeks the patient was convalescent, after which the remedy was continued one week longer in same dose three times a day. He is now as well as before the attack. The result has been most satisfactory. That loathsome disease is robbed of its horrors by this remedy. No pitting,

no disfigurement. I would earnestly call the attention of my professional brethren to its use. It is true, I have but the one case to offer; but had I a thousand more to treat, I would use it in all.

HOSPITAL REPORTS.

A CLINICAL LECTURE AT CHARITY HOSPITAL, CLEVELAND.

BY REUBEN A. VANCE, M. D.,
Of Cleveland, Ohio.

Professor of Operative Surgery and Clinical Surgery in the Medical Department of the University of Wooster; Consulting Surgeon to Charity Hospital, etc.

Tumors of the Breast: The Removal of Benign Growths From Young Women Without Mutilation of the Mammary Gland.

Those of you who have attended my clinics this session are well aware that there are certain tumors of the breast for the relief of which excision of the mammary gland was advised. In the patient from whom this growth was removed excision was not practiced—on the contrary the tumor was extracted, and not only was the mammary gland preserved intact, but the breast escaped mutilation and its integumentary coverings were not scarred. In this particular instance—and it is but one of a numerous class of cases—there was something which justified a very different procedure from that usually adopted in this amphitheater: in what does the difference consist? Review the question of age; you will know that prior to the twenty-fifth year cancer of the breast is almost unknown—that after the forty-fifth year it is very common. On the other hand, the tumors of the breast found in women under twenty-five are either fibromatous or sarcomatous, in the proportion of seven fibroids to one sarcomatous growth. Here, then, is one excellent reason: tumors of the breast in old women are commonly cancerous, those of young women as constantly non-cancerous; the former demand complete removal of the diseased breast, the latter require enucleation of the morbid mass. Second, consider the condition of the patient: in old women the implicated organ has played its part in life and is now entirely functionless; in the young woman the organ has just developed or is just developing, and all its duties are yet to be performed; the tumor in its substance is innocent in character, and can be extracted without injury to the secreting structures of the mammary gland. A third consideration is symmetry of form and bodily looks. To the young woman this is a matter of great importance: to the old woman it is a secondary consideration. The period of life at which a tumor is removed, the nature of the organ from which it is taken, and the influence of the operation upon the appearance of the patient, are not the only circumstances to be taken into consideration in these cases; the behavior of the organ in which the growth is situated, and the influence its developmental, functional or atrophic changes exert over the tumors its textures may give lodgment to, are also matters of moment. When the peculiar character of the mammary

glands is reviewed and their life-course traced, several reasons present themselves why the innocent tumors of these organs in young women should receive different treatment from that accorded the cancerous growths of old women. Without entering into these numerous additional reasons, it will suffice to say that the stimulus of menstruation, of pregnancy, and of lactation, so frequently augments the rapidity of growth and changes the character of benign tumors of the mammary gland, converting them into malignant growths, that it is the imperative duty of the surgeon to remove them at the earliest moment possible. In doing so, however, it is incumbent upon him to operate in such manner as to make sure of excising all the tumor without destroying the gland—the new growth must be taken out, but the symmetry of the patient's form must be preserved. Can this be done? The history of this patient will convince you not only that these new growths can be completely eradicated without injury to the mammary gland, but that tumors of even quite large dimensions can be taken out of that organ without the breast being mutilated or its surface scarred.

The patient, an unmarried lady in her twenty-first year, hurt her left breast during the holiday season of 1879; the elbow of a young lady friend accidentally came into violent contact with her person, striking just on the nipple. Sharp stinging pain followed the blow, but she noticed no immediate swelling, and as all pain subsided in a day or two, she would have thought nothing more of the matter had not a feeling of soreness led her to examine the organ just as her monthly period was commencing, ten days subsequently. She then discovered a lump, the size of an almond, deep in the gland. This alarmed her no little, and as the pain recurred every night after retiring (but was absent during the day) she became nervous and despondent. Having lost her mother some years since, the young lady had no one to whom she felt like going for advice; and while she was brooding over the matter, the pain disappeared and her attention was drawn to something else. With the advent of her next menstrual epoch, the distress was renewed. For the whole year—1880—she suffered in this intermittent way, but at the end of that time she discovered that the tumor was gradually enlarging. During the year 1881 each recurrence of her menses was attended by a decided augmentation in bulk of the mammary growth. The uneasiness and pain still returned at such times, but no distress was experienced in the intervals. About a year ago the gland became so distorted that she was compelled to adopt various devices to conceal the deformity. At this time a lady relative told the patient's father the true state of affairs, and he took her to Cincinnati for professional advice. I then saw her for the first time, and found a globular, firm growth near the centre and posterior part of the left mammary gland. The tumor seemed about the size of a large hen's egg. I urged immediate excision.

I saw nothing more of this patient until the first week in June, 1882. She then presented quite a matronly aspect, and her face bore evidence of the anxiety she had been enduring. Upon examination, the left breast exceeded the

right four inches in circumference; the gland projected abruptly forward, and its integument was tense and shining from distension. The young lady told a pitiful tale of mental agony and broken rest, and the great struggle she had gone through before she could make up her mind to have the tumor excised. Her father had used every inducement to have her consent to the removal of the tumor, but it was only a few days prior to the operation that she reluctantly yielded.

At the time she came under my care in June, I prescribed a mercurial cathartic, and after her bowels had been thoroughly emptied, she was confined to her room the two days preceding the operation for the excision of the mammary tumor. As you will see, ultimately there was nothing in the case to render it worthy of record except the principle upon which the operation was based, and the mechanical details of the surgical measures adopted. There can be little doubt but that all neoplasia of the breasts in young women demand excision so soon as they commence enlarging, or become the site of constant pain: there can be as little question but that, in removing these tumors, it is the surgeon's duty to disfigure these organs as little as possible. The history of this patient is an additional argument for early excision, and the operation performed an illustration of the fact that quite large tumors may be removed from the mammary glands of young unmarried women without the production of obvious scars or perceptible deformity.

Since the winter of 1869 I have been in the habit of making my incisions for the removal of non-malignant growths of the female breast in the fold caused by the fall of the organ upon the wall of the thorax. By this procedure I have excised good-sized tumors of the mammary gland in young women without marring their figures or scarring their chests.

Dr. T. Gaillard Thomas, in a recent article in the *New York Medical Journal and Obstetrical Review*, has systematized this procedure, and given the profession an original and valuable method of treating a certain class of tumors of the breast. He says his method is not adapted for malignant growths nor very large benign tumors. He has found it valuable in fibromata, lipomata, and adenomata, varying in size from a hen's egg to a duck's egg. He operates as follows: "The patient standing erect, and the mamma being completely exposed, a semi-circular line is drawn with pen and ink, exactly in the fold which is created by the fall of the organ upon the thorax. This line encircles the lower half of the breast at its junction with the trunk. As soon as it has dried, the patient is anesthetized, and with the bistoury the skin and areolar tissue are cut through, the knife exactly following the ink line until the thoracic muscles are reached. From these the mamma is now dissected away until the line of dissection represents the chord of an arc extending from extremity to extremity of the semi-circular incision. The lower half of the mamma which is now dissected off is, after ligation of all bleeding vessels, turned upward by an assistant, and laid upon the chest walls, just below the clavicle. An incision is then made upon the tumor from underneath the bistoury, a pair of short volsella forceps is firmly fixed into it, and

while traction is made, its connections are snipped with scissors, the body of the tumor being closely adhered to in this process, and the growth removed. All hemorrhage is then checked, and the breast put back in its original position. Its outer or cutaneous surface is entirely uninjured, and the only alteration consists in a cavity at the former situation of the tumor." This cavity is drained by means of a glass tube, the edges of the wound approximated with care, and the line of incision covered with gutta-percha and colloidion. The ordinary antiseptic dressings are next applied. The stitches are removed on the ninth day; the tube is also taken out at this time; and in cases where these details were accurately attended to, no offensive discharge is encountered, and the patient's temperature never exceeds 100° F.

The operation was substantially that set forth above by Dr. Thomas. In minor points there was some deviation, yet in principle it was the same. In order that there might be as little deformity as possible, the line of incision was distinctly outlined with nitrate of silver, and on each side, above and below, opposite points were marked, through which subsequently stitches were passed. Experience having shown that a disagreeable and persistent thickening is apt to develop at the place occupied by the glass tube, the necessity for the latter was obviated by employing a large number of stitches and then obliterating the cavity within the gland by compressing the breast with a carefully applied flannel bandage. It was thought that some arrangement would have to be made for drainage of the cavity in the breast: since the tube was abandoned and the gland compressed, there has been no demand for drainage materials of any kind. Should the mamma become distended, a probe can be introduced at a dependent point and the fluid discharged. In my last five cases treated with compression and without drainage-pipe, the cavity in the breast united by first intention as readily as the wound in the integument.

Ten months have elapsed since this young lady was before you. The change in her general appearance is as marked as the modification in outline of affected gland is distinct. She has once more become herself in every way, and presents herself here, not that she needs surgical aid, but that you may see how time has treated the organ then operated on. A thin white line marks the cutaneous incision; please note that as she stands erect you can notice no difference between the mammary glands of the two sides. She revisits us in company with a friend who requires an operation. It is a pleasure to meet with patients who appreciate what has been done for them. In this instance the young lady was not a clinical case, yet she voluntarily comes before you that you may see the result of an operation that to her was of such vital moment. After glancing at this result, I am sure you will hesitate long before performing any of the operations this procedure is designed to supersede—operations, the disfiguring character of which had much to do with preventing patients accepting the undoubted benefits they offered, and indirectly caused many women ultimately to suffer death from mammary cancers who should have escaped that fate. This pro-

cedure of Thomas will not only remove deformity and alleviate distress, but, by inviting early excision of lesions of the breast, will certainly tend to materially diminish that form of cancerous disease of the mammary gland in which carcinoma supervenes on long-standing benign growths of that organ.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, May 3, 1883.

The President, R. A. Cleemann, M. D., in the chair.

Dr. Wm. Goodell related the history of

Three Stubborn Cases of Vesico-Vaginal Fistulæ Successfully Treated After the Operation Without the Use of the Catheter.

The first one, after a non-instrumental labor lasting from a Tuesday evening, when the membranes broke, to a Friday night, found that her urine dribbled away immediately after the birth of the child. The fistula was situated so close to the cervix as to implicate it, and was quite large. Sixteen months after the accident she was operated on by a distinguished surgeon, whose success in uro-genital fistulæ is very great. He turned the cervix into the bladder, and successfully closed up all the rent save a small portion of it. On this fistula he operated three times without any union whatever. In each instance the urine dribbled away before the stitches were removed, and on two occasions an alarming hemorrhage came *per vaginam*. This information Dr. Goodell obtained from the surgeon himself.

Early in 1877, Dr. Goodell operated on her at the Hospital of the University of Pennsylvania and put in Sims's self-retaining catheter. Eight sutures were needed to close the opening. The next day a hemorrhage from the bladder, possibly menstrual, took place and lasted several days. A fever also set in which gave some alarm. When the stitches were removed very little union was found to have taken place. Four months later Dr. Goodell operated for the second time, and thinking that the vesical hemorrhage in the preceding operation was caused by the irritation of the self-retaining catheter, he treated her without one. The first twenty-four hours her urine was drawn off every four hours, but afterwards she was allowed to pass it herself. No hemorrhage occurred, and perfect union took place.

The second case was also one of tedious labor in which the forceps were not used. The fistula at first was a very large one, and was most skillfully closed by an excellent surgeon. A very small fistula, however, remained at each angle of the wound. These defied repeated operations on his part, and the case finally drifted into Dr. Goodell's hands. Twice the latter operated at his private hospital on these fistulæ, using the Goodman self-retaining catheter, but each time vesical and uterine tenesmus set in and the result was a failure. Both fistulæ were then burned with the actual cautery and one of them closed up, but the larger one resisted this treatment as well as that by nitric acid. He then operated upon it a month

ago for the third time, dispensing with the use of the catheter. The lady was instructed to pass her water before the desire was urgent. Neither vesical nor uterine tenesmus occurred. The stitches were left in for fourteen days and union was complete.

The third case was the result of a short labor and the cause of the fistula is obscure, as the lady was attended by a midwife, who pulled and tugged away at something after the birth of the child. The late Dr. H. Lenox Hodge had operated five times upon it, closing all but a small fistula which lay at the junction of the neck of the bladder with the urethra. Dr. Goodell closed this fistula at the Hospital of the University three weeks ago with eight stitches, and fearing that the catheter would interfere with union, dispensed wholly with it. The success was complete.

From these cases and from others which he had met with, Dr. Goodell was led to think that the catheter might as a source of irritation often be dispensed with very advantageously in the treatment of these fistulæ. He cited the practice of the late Dr. Simon, of Heidelberg, who was a very successful operator, and yet rarely resorted to its use. He also called attention to the fact that in these cases, and in the very great majority of the cases he had met with, the forceps had not been resorted to, showing that it was not the use of that instrument, but its neglect or the delay in its use, that caused the mischief. In fact, he could not recall a case in which the lesion could be attributed to instrumental delivery. In the general experience of surgeons, very small vesico-vaginal fistulæ were harder to cure than moderate-sized ones. One reason for this is attributable to the fact that they usually are found in sites difficult to reach; and another that the operator is unwilling to enlarge the small opening by bold incisions, and fails from too small a denuded surface. Including the one previously referred to, he had closed two of them by means of the actual cautery.

Dr. Albert H. Smith remarked that these cases were of great interest. He had been taken by surprise when Dr. Simon announced his plan of treatment without the catheter, as he had been afraid of the strain on the stitches resulting from the accumulation of urine in the bladder. The presence of the self-retaining catheter must necessarily be a source of irritation and vesical tenesmus. The small holes in its bulb may become occluded by mucus or clot, and then it would act as a plug instead of a drain. In those cases in which the loss of substance in the vesico-vaginal septum has been very great, and the mucous surface of the bladder has been prolapsed into the vagina, the capacity of the bladder becomes small, and it must be emptied frequently or the tension on the stitches becomes too great.

He had been gradually led to the conclusion that it would be better not to use the catheter after trachelorrhaphy and perineorrhaphy, unless called for by special circumstances. There are cases in which, in consequence of mental influence or the effect of position, the patient cannot pass her water for weeks after labor in which no injury or long or undue pressure has occurred.

Dr. R. P. Harris had recently operated for the restoration of a very long perineum. The last

stitch was almost on a line with the orifice of the urethra, and the nurse was not able to introduce the catheter. He placed the patient in a sitting position to pass her water, and used a male catheter, tied on the tube of a Davidson syringe, to wash out the vagina.

Dr. Goodell is by no means a convert to treatment in this class of cases without the employment of the catheter. He has been too successful with it. He prefers the Goodman self-retaining instrument, but he makes certain that it does not impinge on the wound. He has realized the influence of mind and of position on the ability to pass water, and he thinks the use of ergot, so general before the third stage of labor, is one cause of the difficulty, as it is quite possible that it may cause a spasm of the urethral constricting fibres. He would like to dispense with the use of both catheter and syringe after perineorrhaphy, as he has found injuries to the anterior angle of the wound, by the syringe and the fingers of the nurse while introducing the catheter. He has been in the habit of putting one stitch through the sound skin above the denuded surfaces to prevent this injury. In one case recently the Goodman catheter slipped out twenty-four hours after perineorrhaphy, and he did not replace it, the wound healing. He always uses the catheter after trachelorrhaphy.

Dr. W. Goodell also exhibited

Two Ovarian Tumors, one of them of Doubtful Character.

The one of doubtful character was removed from an unmarried woman, aged 27, who had not menstruated for over a year. It was first discovered nine years ago, but gave no trouble until two and a half years ago, when ascites set in. She had been tapped fourteen times when Dr. G. first saw her. She was very thin, pale, and so weak as to keep her bed. He recognized a hard tumor floating in the ascitic fluid, giving the feeling of balottement, and diagnosed it either as a solid ovarian tumor or a pedunculated fibroid.

On the 18th of last April he removed it at the University Hospital, and found it to be a hard, solid nodular tumor of the right ovary, with evidences of papillomatous degeneration. It had merely omental adhesions, and had a long slender pedicle twisted many times on its axis. It was evident that the ascitic fluid was secreted directly from the tumor, and did not come from pressure on abdominal veins or from irritation of the peritoneum.

The other cyst was removed also at the Hospital of the University, and on the same day, from a married woman, aged 26, who noticed it two months after her marriage and about four months ago. The cyst was as large as the adult head, and was apparently attached to the womb, which was drawn upwards and gave a measurement of four inches. It was operated on early because it caused great vesical disturbance. The lower portion of the cyst was found enveloped in the broad ligament close up to the womb and had to be enucleated. It was this condition that gave the symptoms of uterine attachment. The cyst was that of the left ovary, but as the right ovary also presented tokens of degeneration it was also removed. Both women recovered promptly, although the first one had on the third day a severe

attack of mumps, which appears to be prevailing in this city as an epidemic. The ascitic fluid, which was straw-colored and syrupy, was not examined microscopically.

Dr. M. O'Hara wished to know how Dr. Goodell could decide quickly between mumps and septic parotitis. He also spoke of the reflex action of the sexual organs as shown by the frequent occurrence of salivation during pregnancy. In a recent case of cancer of the rectum, the first symptom observed was excessive secretion of saliva.

Dr. Albert H. Smith remarked that mumps was a very interesting and very perplexing disease. He has seen cases of extension of the disease without retrocession, in adult women, to mastitis and ovaritis—the swelling of the parotid gland being rapidly followed by the involvement of the sexual glands, the inflammation of the ovaries being accompanied by local peritonitis. A singular question was raised by the case of a young man who went to Florida directly after marriage, and on the return trip by sea experienced a severe attack of mumps; it was complicated by orchitis, the inflammation being of high grade with great increase of temperature and rapid pulse. No atrophy of the testicle has occurred, but the union has been sterile, and there is no known fault on the part of the wife. The semen has not been examined microscopically to ascertain the presence of spermatozooids. The mastitis accompanying mumps has never, in Dr. Smith's experience, run into suppuration, but is accompanied by febrile action of a high grade. He has seen the ovary, the original point of attack, the inflammation of the mammary gland being later. It is a marvel of pathology that this disease, which affects in childhood the salivary glands only, should in adult life affect the sexual glands also. He has never seen a case of atrophy of the testicles following mumps.

Dr. Goodell recognized mumps in this case by his experience in two previous cases of mumps with severe symptoms in adults. The pulse does not become so frequent, as in septicæmia, and the eye remains clear and does not acquire that glassy appearance so indicative of a fatal issue. Dr. Goodell has never seen the involvement of the breast and ovary. A peculiar relation between the sexual organs and the glands of the neck is shown by a habit of the Roman matron who measured the throat of her daughter before and after the night after marriage, to ascertain if the young husband had properly performed his marital duties, and if they had been properly received.

Dr. Albert H. Smith exhibited a set of hard rubber

Urethral Dilators.

The set consists of ten pieces, with two handles into which they can be screwed; the smallest bougie is twenty millimetres in circumference at the point, and twenty-eight millimetres at the largest part, the tapering in each bougie being eight millimetres, and a difference of six millimetres between each one and the largest circumference of the next in the scale. The largest one is eighty-two millimetres at the largest part and would be useful as a rectal dilator. He had been very much surprised at a statement made by Dr. Emmet at the last meeting of the Gynecological

society in Boston, that dilatation of the urethra almost universally causes laceration, and is followed by permanent incontinence of urine. Dr. Smith has been in the habit of doing it frequently and fearlessly, without hesitation, not only in diseases of the urethra and bladder, but for exploratory purposes and for the removal of stone as a step in the operation of anterior elytrorrhaphy; but also that by means of a finger in the bladder he may judge of the thickness of the walls in denuding the vaginal surface, and place his sutures satisfactorily. He has never had incontinence of urine to last over twenty-four hours from this procedure.

Dr. R. P. Harris had seen a large number of dilatations of the urethra without any bad effect. He would consider the method of Dr. Smith is better than any other plan, as it would make a perfectly even and uniform pressure on every portion of the urethra, with a very gradual action, free from the dangers incident to the opening of any form of instrument with blades.

Dr. Goodell was much obliged to Dr. Smith for exhibiting these instruments, and would get a set of them. He has entirely dropped Simon's dilators, and has for some time been using his little finger as the best dilator. He has not had any trouble from laceration or incontinence. In one case in which he resorted to dilatation and treatment to the mucous surface of the bladder as a cure for cystitis following labor, incontinence remained for a long time, but gradually disappeared. He knew of laceration and incontinence in two instances resulting from the use of the thumb as a dilator. Dilatation alone is a good treatment for many cases of irritable bladder.

Dr. Wm. H. Parish related the case of a widow operated on by Dr. Smith by dilatation, for the relief of a very aggravated case of irritable bladder, the result of a gonorrhœa contracted years before from her husband, and which had been followed by cystitis. It was greatly relieved for several months, but not cured by dilatation, but the relief was only temporary. The patient passed under the care of Dr. J. Lenox Hodge, who cauterized the urethra by means of Paquelin's cautery. In consequence of the illness and death of Dr. Hodge, she came again under the care of Dr. Parish, who commenced treatment by the injection of a solution of nitrate of silver, very strong at first but weaker on subsequent applications. The trouble has passed entirely away. There are two causes of fissure in dilatation; the first is too rapid expansion of the dilator; the second, changes in the mucous membrane, as from inflammatory action, particularly if caused by gonorrhœal poison.

Dr. Chas. H. Thomas had lately procured a set of nickel-steel instruments of about the same taper and for the same purpose as those exhibited by Dr. Smith. The set consisted of sixteen pieces. They were one-and-a-half mm. as the scale, and each dilator tapered five mm. from the point to the largest circumference of the shank; they ranged from twenty-five to fifty mm. He has tried in some cases using every second instrument, making rises of three mm., but has found that the pain was increased by so doing. He has never known of a case of incontinence caused by dilata-

tion, but has heard of such from the hands of two celebrated surgeons of this city. He thinks dilatation to the size of the finger a good treatment for the relief of irritable bladder in connection with irritation of the urethra and neck of the bladder. He related the history of two cases in which this condition was complicated, and made persistent by sphincterismus of the sphincter-ani muscle; dilatation of the urethra in these cases, although a benefit, did not cure the trouble, but when to this was added dilatation of the sphincter-ani, so that two fingers could be introduced back to back, and a good dilatation secured, the cases were permanently cured.

Dr. B. F. Baer has practiced dilatation of the female urethra a number of times, and has had no instance of continued incontinence. He would, however, question the propriety of ever using a large-size dilator, except for the purpose of removing a calculus from the bladder, and even in that case he thought it might be better to allow the stone in the grasp of the forceps to finish the dilatation, than to use mechanical dilators to secure the full extent needed. In one instance incontinence lasted several weeks after dilatation, but final recovery was complete. Solutions of carbolic acid having been applied in the meantime for the cure of an irritability of the bladder and urethra.

Dr. Parish would like to hear from Dr. Smith respecting the indications for probable success in treatment by dilatation of the urethra for the relief of irritation of the bladder.

Dr. Smith in reply to Dr. Baer remarked that no cavity of the body should ever be dilated beyond the actual necessities of the case; such a principle is unquestionable; but no form of dilator could be worse than the irregularities and roughness of a calculus, increased in size, as it would be by the grasping forceps, which would present but two points of contact with the urethra, and render laceration quite probable. In a patient recently under his care he had reason to suspect the existence of papillomatous growths on the mucous surface of the bladder; he dilated the urethra, using the largest size of Simon's dilators and completing with a Molesworth dilator expanded very slowly. He was able to evert the bladder through the urethra, and removed the vegetations by means of scissors. There was no laceration nor incontinence resulting from this procedure. The danger is in too great haste.

In reply to Dr. Parish, he said that dilatation is usually resorted to for exploratory purposes, removal of stone growths on the vesical wall, or to ascertain the thickness of the wall of the bladder, and to introduce a finger into that viscus to guide the sutures in plastic operations upon the vagina. Irritability of the neck of the bladder can generally be relieved by dilatation, but it sometimes fails to cure.

Dr. Smith prefers hard rubber to plated metal as the material for the dilators; it is lighter in weight, is not liable to corrosion, and is more easily kept clean. He thinks the multiplicity of instruments in Dr. Thomas' scale a disadvantage, and that time is lost and irritation caused by introducing several instruments, in place of allowing one to remain a longer interval.

EDITORIAL DEPARTMENT.

PERISCOPE.

Dyspepsia—Ulcer of the Stomach.

Dr. Donald W. Hood read a practical paper on this subject before the West London Medico-Chirurgical Society, *Medical Press*, March 7, 1883.

In this paper the author maintained that the more our experience of the natural history of disease increased, the more we must accustom our selves to the fact that dyspepsia should be looked upon as symptomatic rather than generic. He drew especial attention to those cases of stomach lesion in which dyspepsia plays such an important part as a symptom, and suggested that in many cases of so-called simple dyspepsia there was a definite lesion of stomach coat. He held that the carefully compiled category of symptoms incidental to ulceration of the stomach suggests that its diagnosis is easy, the very opposite of that being clinically the case. In the early part of 1879 he had placed under his charge, by Sir William Gull, a gentleman, æt. 40, who had spent many years of his life in the colonies, where he had sheep-tracks. For eight years he had been a sufferer from dyspepsia, the commencement of which he attributed to irregularities of diet. He first felt pain over the region of the stomach; soon he suffered from attacks of vomiting, and acid water-brash. Failing to obtain relief, he came to England. When first seen by him, eighteen months after his arrival, his symptoms were much intensified. He detected blood in his vomit. Presently the stomach became intensely irritable, the patient being supported entirely by means of nutrient enemata. Slowly the grave symptoms subsided, and he regained flesh. In six weeks he went about as usual. But three weeks afterwards, while sitting, on moving suddenly, he felt a pain in the stomach, and died within twelve hours. The *post mortem* showed perforation of the stomach at its anterior base. A small healed ulcer, at its base no thicker than tissue paper, had given way, and the contents of the stomach had become extravasated into the peritoneal cavity. The most instructive part of the examination was the condition of the stomach in the immediate vicinity of the pyloric orifice, which was honey-combed with the remains of cicatrices of old ulcers that presented small depressions corresponding to the position of gastric follicles, which are in greatest abundance at the pyloric extremity. The condition of the mucous membrane appeared to supply abundant cause for all the gastric trouble which had caused so much pain during the preceding eight years. It happened that another patient, whose symptoms bore some resemblance to those of the case he had stated, was under his care at the same time. This was a German gentleman, æt. 40, who had suffered from painful digestion about fourteen years. In the early days of his illness he had felt pain after taking food. Later, he began to suffer from occasional attacks of vomiting. He had been repeatedly treated for dyspep-

sia. When first seen he was rather emaciated. The stomach usually emptied itself at the end of the day. On several occasions a coffee-colored matter had been ejected, and altered blood was sometimes mixed with the vomit. The stomach descended below its natural limit, and a small lump could be felt in the epigastric region, indicating obstructive disease of the pylorus. Upon treatment, flesh was gained, the vomiting ceased, and the stomach recovered its natural size; but the lump remained. Subsequently, he went to his business abroad, when the symptoms returned, and he died of exhaustion. Statistics proved that ulceration of the stomach was of very frequent occurrence, but beyond question the symptoms of ulceration varied very greatly. Although hæmorrhage was a symptom of the utmost moment, it was not judicious to wait for the presence of blood before inferring the existence of ulceration. All writers on the stomach treated ulcer as a chronic disease, but none of them advised such treatment as would be adopted in regard to an ulcer occurring on the surface of the body. In treating assumed ulcer, he thought it imperative that the patient be kept in a recumbent position, in order that the stomach walls might be in a state of rest. When there was much enlargement of the stomach he generally used a counter irritant, and he freely prescribed the various preparations of opium in those cases where there was no doubt that the dyspepsia did not arise from hepatic engorgement; but he found that it not only stimulated the bowels, but also made the patient intolerant of restraints. Such treatment in the early stages of dyspepsia was sure to result well. Where the presence of ulceration was well marked, such treatment should be resorted to as would be insisted on if the ulcer occurred on the surface of the body. He had found this method of treatment productive of the best results in the case of a lady who, at the time of first seeing him, was afraid to take the simplest food lest its ingesta should cause her pain. On making a careful examination of the abdomen he failed to find enlargement, but in the epigastric region there was a spot most tender on pressure. He ordered her to bed, recommended rich milk and light broth as diet, and prescribed six drops of laudanum every four hours. Iodine was suggested as a counter irritant. A simple soap-and-water enema was to be used every other day. From the first the patient's progress was satisfactory. Pain ceased, there was no vomiting, and the bowels acted regularly. She left her bed in fourteen days, and recently he received a letter stating that she was quite well. He regarded the case as representing ulceration or excoriation at that stage in which great good can be done by a decided course of treatment.

Lime Juice.

From the *Chemist and Druggist* we note that in a paper recently read before the Liverpool Chemists' Association, Mr. Michael Conroy F. C. S., gave an

interesting account of the production of Montserrat lime-juice, and a summary of his experiments on over 4,000 samples of this product.

Lime-juice is the expressed juice of the fruit of *Citrus limetta*, a member of the orange tribe (Aurantiaceæ). The tree is a thorny, bushy evergreen, with handsome dark foliage of exquisite fragrance. The flowers are white, resembling orange blossoms, and their perfume is equally delicious. The tree flourishes best in a light sandy soil, near the sea, and comes into full bearing in about seven years after the seed is set. It grows wild in nearly all tropical countries, but is now largely cultivated in the island of Montserrat. The fruit is about one-half the size of a lemon, with a smoother and thinner rind, oval, rounded at the extremities, and of a pale-yellow or greenish-yellow color. The exterior of the rind possesses a fragrant odor, and a warm, aromatic, slightly bitter taste, somewhat similar to that of the lemon. The juice, when fresh and sound, is sharply acid, with a peculiarly refreshing and grateful flavor. In Montserrat the lime-fruit harvest is heaviest from September to January, but a good supply of fruit is yielded throughout the whole year. Here, where the lime tree is specially cultivated for the sake of the juice, the work is done in a systematic manner, with suitable machinery. The fruit, after collection, is taken to two central factories, where it is sliced by water-power, and then squeezed in huge wooden presses, the juice being run into puncheons and quickly bunged up. Choice fruit is alone used, and only about two-thirds of the juice is pressed out, thus ensuring greater freedom from mucilaginous and pulpy matter. The further pressings, together with the juice of the unsound fruit, are evaporated to the consistence of treacle, and sent over to this country for the manufacture of citric acid.

It is chiefly owing to these precautions that Montserrat lime-juice is so much superior to that produced in Jamaica and elsewhere, where no care or supervision is exercised in its preparation.

Lime-juice contains citric acid, gum, sugar, albumen, extractive matter, inorganic salts, and water. The most important constituent is the citric acid, but as to the percentage of citric acid contained in juice authorities disagree considerably. Mr. Conroy, however, by a record of the citricity of over 4,000 samples, which he has examined during the past few years, has fairly settled that question. Each sample examined has represented a puncheon of over 100 gallons, and has been taken from the puncheon on the quay, after landing. The citricity has been estimated by volumetric estimation with caustic soda solution. The free citric acid in the 4,160 samples varied from 6.7 to 10.05 per cent., representing 10.72 to 16.08 oz. per gallon. The average of the whole was 7.84 per cent., representing 12.54 oz. per gallon.

Mr. Conroy has found that samples of the lime-juice bottled and kept in the laboratory for twelve months, with no preservative added, and exposed to light, remained perfectly sweet and sound. One sample filtered, retained its full citricity, but another sample which had been filtered had lost .02 per cent. Mr. Conroy accounts for this difference by supposing that the essential oil emulsified by the mucilage and sugar of the juice in the unfil-

tered sample had helped to preserve it. On the basis of this experiment Mr. Conroy concludes that for the purpose of supplying lime-juice for ships, the addition of spirit is not necessary. Spirit is necessary, however, for the preservation of lemon-juice, which contains much more sugar and mucilage. But the 15 per cent. of proof spirit, ordered by the Board of Trade, is insufficient and useless. At least 30 per cent., or, better still, its equivalent for a stronger spirit, is necessary.

In the Royal Navy only lime-juice is used, with the gratifying result that scurvy is now practically unknown. In the Merchant Marine Service, however, lemon-juice is chiefly used, owing to its cheapness, and here cases of scurvy are frequently occurring; not, Mr. Conroy thinks, that lemon-juice is inferior to lime-juice as an antiscorbutic, but simply that it soon becomes inert and useless by fermentation.

The Treatment of Phthisis by Iodoform.

The *Brit. Med. Jour.*, April 28, 1883, says that Dr. Dreschfeld has continued his observations since his first communication (*Brit. Med. Jour.*, 1882, vol. ii., p. 169). The favorable opinion then formed has been further strengthened by the results obtained. Of sixty-four cases of confirmed phthisis, more or less advanced, and concerning to a great extent out-patients at the Manchester Infirmary thirty-four cases only had been under treatment sufficiently long to be available for the purposes of this communication. Of these thirty-four cases, four were in so far advanced a condition that the iodoform was only borne in the form of inhalation, but gave no results; two cases were complicated with amyloid disease, and here also the iodoform was useless. Of the remaining twenty-eight cases, ten showed either no improvement or only a temporary improvement (increase of weight, improvement of appetite, decrease of cough and expectoration); while the physical symptoms showed no alteration at first, but afterwards the phthisical process gradually advanced and associated again with loss of flesh, night-sweats, etc. Of the remaining eighteen cases, some showed slight but steady improvement, broken only temporarily by a fresh cold or some complication, such as gastric catarrh, pleurisy, etc.; whilst in six cases the improvement was most marked and beyond all expectation, the increase in weight amounting in one case to fourteen pounds, in another to ten pounds, and in a third to eight pounds, in one month. The physical symptoms also improved; the sputa, however, continued to contain tubercle-bacilli. The iodoform treatment was also tried in six cases of incipient phthisis. Of these, two had only been under treatment for a very short time. Of the four remaining cases, two showed no improvement; one was at once benefited; cough and expectoration entirely ceased; the apex-catarrh disappeared; and the patient felt now perfectly well.

In the second case (reported in the *British Medical Journal*, February 17, under A. S.), the treatment was equally successful—only, however, after having been continued for a longer time. There being an almost entire cessation of cough, it was difficult to obtain any sputa; one specimen, however, was obtained, and this was found free from

bacilli, whilst before they were found abundantly. Two cases of laryngeal phthisis, treated both internally and by inhalation, and also locally by the application of iodoform-powder to the ulcers, gave satisfactory results; the ulcers cleared and became smaller, and the general condition improved. The iodoform was given in the form of pills (one grain of iodoform, two grains of croton-chloral, one minim of creasote), and in the form of inhalation (twenty grains of iodoform, twenty minims of oil of eucalyptus or ten minims of creasote, and half an ounce each of rectified spirit and of ether). The inhaler used was one devised by Dr. W. Roberts, consisting simply of horse-hair matting, to the inner side of which was attached some flannel or cotton-wool; and on this the inhalation-mixture was dropped. The cost of the inhaler was about threepence. Where the pills were badly borne (especially in women), the iodoform was added to cod-liver oil. In very young children, iodoform inunction, made with olive-oil or vaseline, was to be recommended; while older children seemed to take iodoform, either as powders or in small pills, very well. The good effects of iodoform seemed to consist in the following:

1. Increase of weight.
2. Increase of appetite.
3. Diminution of cough and expectoration.
4. Diminution or even total cessation of night-sweats.

5. The temperature was often a little lowered. No symptoms of iodoform intoxication had ever been seen. Several medical men, who had tried the iodoform treatment, had also obtained very satisfactory results.

The Diagnosis of Rotheln.

Dr. Edmond Shackleton thus writes to the *Brit. Med. Jour.*, April 21, 1883:

The diagnosis of r $\ddot{o}$ theln is of importance, as it is a trivial disease compared with those which it resembles. I have just had a case of it in a married woman over thirty, and I particularly noted the points by which it might be diagnosed on the first day of the eruption. My patient had complained of a sore-throat and soreness of some glands at the side of the neck for three days previous to the eruption. On April 9th, she found herself, on awakening, covered, on her body, upper extremities, face, and neck, with a red rash, the legs remaining unaffected till the third day. The case differed from one of scarlatina both in the appearance of the rash and in the general symptoms. The eruption consisted of spots like those of measles, and was particularly vivid on the face, so as to be conspicuous from a distance, which is not the case in scarlet fever. In spite of having some frontal headache and lumbar pain, she expressed herself as feeling quite well and bright; whereas, in scarlet fever at this stage, there is languor and prostration, and often nausea and vomiting. She had some shiverings, and loss of appetite, and thirst. Temperature 102.2°; pulse 100. In the evening, the temperature had fallen slightly, and next morning was 99.5°, and on the fourth day had reached the normal. From measles, it was distinguished by the absence of coryza, lachryma-

tion, etc., and cough. The spots are like those of measles, but are regularly distributed instead of appearing in patches. The skin felt tense, but there was no itchiness or sensation of burning. The chief diagnostic features of the disease appear to be that it presents the throat of scarlet fever with the eruption of measles, but without the coryza of the latter, and without the depression, rapid pulse, and high temperature of the former. My patient was sure that she had had scarlet fever and measles in her youth. No desquamation has followed.

Antiseptics in Phthisis.

Dr. Wm. Porter, Physician to Throat and Lung Department, St. Luke's Hospital, St. Louis, thus summarizes in the *Lancet and Clinic*:

Proven, it seems to me, are these two propositions:

1. Phthisis is a specific disease from a specific cause.

2. Phthisis may be produced by absorption of tuberculous matter in contact with the mucous membrane of the air-passages or intestinal tract.

There is also evidence that the energy of this tuberculous matter is due to germ development and progression.

Hence the value of antiseptic influence in the treatment of phthisis, not only in the later stages during pus-production and absorption, but also in the earlier process of infection.

One great demand is for that which, by local and internal use, may meet and destroy the septic agencies of disease. Such a remedy must be effective, unirritating and non-poisonous, susceptible of ready dilution and easy absorption, and withal inoffensive in odor and taste.

Carbolic acid and iodoform do not fully meet these requirements, and less harmful yet no less potent means of antagonizing contagion and putrefaction are finding favor.

The compound known as Listerine has, for nearly two years, served me better than any other remedy of its class, and, in the treatment of phthisis, has almost supplanted in my practice all other antiseptics. In treatment of diseases of the upper air-passages, it is pleasant and does not irritate; in the fermentative dyspepsia so often accompanying phthisis, it is safe and efficient.

It is the most powerful non-toxic antiseptic I have yet found.

The Value of Some Nitric, Nitrous, and Nitro-Compounds in Angina Pectoris.

With the view of determining whether it is the nitrous acid or its base that proves so beneficial in angina, Dr. Matthew Hay has instituted some investigations, which he publishes in the *Practitioner* for May, 1883; the following are his conclusions:

So far as at present known, the nitrogen-containing remedies for angina pectoris may be divided into two classes, the one consisting of combinations of nitrous acid with metallic oxides or alcoholic radicals, the other comprising a peculiar class of nitric ethers, obtained from the higher alcohols, whose decomposition within the body results in the production of nitrous acid. In both classes the action of the compound is ultimately

dependent on the nitrous acid present. Typical examples of the first class are nitrite of sodium and nitrite of ethyl, and, of the second class, nitro-glycerine. To these classes might be added another containing such substances as compounds of amyl, whose action is similar to that of nitrites. But, limited as this group at present is to compounds of amyl, it is not one to be chosen in the treatment of angina pectoris. The dose required is large, and the action is not rapidly produced, and disagreeable after-effects are apt to occur; and altogether I am very doubtful of its always acting so well as it did in one of my patients.

The Influence of Alcoholism on the Development of Skin Diseases.

Janin, *Th. de Paris*, 1881, says:

1. Alcohol is neither destroyed nor transformed within the organism, but remains there for a considerable length of time, and is eliminated, in great part, if not entirely, by the kidneys, the lungs, and the skin.

2. The bodily disturbances occasioned by this agent consist partly in intense congestion of the organs with which it is chiefly brought in contact, and partly in a profound alteration of the tissues and more important nutritive functions, which terminates in the development of genuine cachexia.

These disorders produce their most injurious effects on certain organs, particularly the skin, thus making it easy to explain the influence exerted by alcoholism upon the several varieties of cutaneous disease.

3. Alcoholism, by its unaided power, is capable of evoking morbid cutaneous phenomena, whose underlying cause, however, is to be sought for in some special constitutional predisposition, i. e., in either the arthritic, herpetic, scrofulous, or syphilitic diathesis. But these effects are seldom met with; and what we most frequently observe, and should always bear in mind, in respect to this condition, is the important part it performs in the maintenance and aggravation of pre-existing disease, to which it sometimes imparts a very serious character.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—"Science," published weekly at Cambridge, Mass., is, so far as the general aim of its contents is concerned, an excellent journal. But it is very regrettable to notice the narrowed, prejudiced, and carping spirit in which it is edited. There are few good words in it for anybody outside of Boston, and those who write for it seem to aim to vindicate their ability by a studiously depreciatory reference to other workers. There is in it too much the style of the *New York Nation*, which is too omniscient to be truthful, and too feeble to correct its own errors. Such is not the spirit of true science, and should not be of any journal that bears that name.

BOOK NOTICES.

Transfusion—Its History, Indications, and Modes of Application. By Chas. Egerton Jennings, L. R. C. P., etc. Bailliere, Tindall & Cox, London, 1883. Cloth, 8vo., pp. 69.

The operation of transfusion has had periodical revivals, and here and there ardent advocates for centuries. Now and then, a wonderfully brilliant result is obtained by it; generally it is a disappointment. Dr. Jennings takes up the question of its utility in a strictly practical manner, and from personal observation of its effects. He has invented a siphon for intravenous injection and immediate transfusion, which he figures and describes. The operation he recommends is not, however, properly transfusion. He does not draw blood from another subject, nor, in fact, does he use blood at all, but a saline alcoholic fluid, which he believes acts almost as well, and which can be prepared any time at a moment's notice. This removes one of the greatest difficulties about transfusion, the securing a donor for the necessary blood.

An excellent bibliography of the subject closes the volume.

The Transactions of the American Medical Association.

Vol. XXXIII., Philadelphia, 1882, pp. 669.

In this, which we presume is the final annual volume of the American Medical Association, we have the usual minutes and formal matter, and a very fair number of essays. The most of these have already been communicated to the profession in various manners, so that there is little which is new to readers of medical periodicals. There is, however, an advantage in reading an author's views in full, and those who have had their interest excited by abstracts of the papers presented at the meeting will be glad to receive them in their perfect form in this volume.

Among so many well known writers, it were invidious to draw distinctions. Moreover, as matters now stand in medicine, hardly any one but a specialist can judge of specialists' papers. Hence, we shall not undertake to pronounce on the merits of the articles read before the different sections. There are few which are not by men well known for their thorough study of their respective branches. Of many we have had, or shall have, occasion to make extracts and notices in our columns.

Finally, we may say, the volume is one quite equal to any of its predecessors—and this is high praise.

June 16, 1883.]

Editorial.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

MOTIONS OF THE INTESTINES.

Nothnagel has conducted a series of observations regarding the motions of the intestines, and published the results of the same in Zeitsch. f. Klin. Mediz., iv., p. 532. The experiments were performed after the method of Sanders*; they confirm the opinion of Hongkerst,† that we never find anti-peristaltic motion in the normal uninjured intestine. If unirritating, indifferent fluids are injected into the bowels either in the form of clysmas or by puncture with an hypodermic syringe, no anti-peristaltic motion sets in, but such does happen when the solution containing 27-20 p. ct. of chloride of sodium, or a similar irritating fluid is introduced in any way into the alimentary canal. The anti-peristaltic motion may take place in the small as well as in the large bowel.

Were acute closures of the bowels artificially produced, no anti-peristaltic motion was noticed. Had the intestine been quiet before the sudden closure, then it also continued that way after the same; was the bowel before in motion, the latter also continued after the closure; but this depended greatly upon the contents, viz: if the bowels were empty, there was no motion; were feces contained in them, then the upper part, which they had left, was motionless, while the lower part, with its contents, continued the motion. This fact goes to prove that stercoraceous vomiting in cases of convolvulus or intussusception or any other closure of bowels, cannot be caused by the increased anti-peristaltic motion, and that Sweiten's theory regarding the pathology of this symptom is correct.

In catarrh of the intestines, if rapidly developed in consequence of some acute irritant, there develop themselves first strong contractions near the inflamed tissue; as soon as this part of the bowels is empty, these cease also. Nothnagel believes, however, that the increased irritability of the diseased bowel continues. He also noticed that in rabbits invagination would take place with ease and rapidity whenever the motions of the bowels have been increased very much; a fact

* Centrbl. f. d. Med. Wissensch., 1881, p. 479.

† Ibidem, 1873, p. 471.

which would go to explain many a case of intus-susception in men, where hitherto no cause could be detected.

We further learn from Nothnagel's observations, that the sulphate of sodium acts far more promptly on the intestines than the sulphate of magnesium, and that it is also far less irritating in character; the redness and local exudation following the application of the latter remedy being invariably more intense than the same symptoms caused by sulphate of sodium. It is a remarkable fact, that in our country and in England, Epsom salt is the remedy usually employed when the physician wishes to administer a saline cathartic, sulphate of sodium being left to the veterinary surgeons, who, on account of the cheapness of Glauber-salt use it in horses. But if all practicing physicians were aware of the fact, that while being far milder in its action, so mild that it can with safety be administered to the youngest child, half a teaspoonful of Glauber-salt will go as far regarding its cathartic effect, as about a tablespoonful of the far stronger, but usually-employed Epsom salt, and that besides, the latter has a more disagreeable taste than the former, there soon would be few physicians who would still use the Epsom salt; most would do what their German confrères have been for fifty years in the habit of doing, give preference to the milder, surer, and better-tasting Glauber-salt.

THE PATHOLOGY OF DIABETES.

All our acquaintance with diabetes, is, to say the least, very vague. Of its treatment, we are still quite ignorant, and in reference to its pathology, we are so much in the dark, that an English physician recently made the statement before the Pathological Society of London, that, in his opinion, diabetes has no pathology, that it is a functional disease.

The attention of this society has been lately devoted in an especial manner to this subject, and at a recent meeting (*Brit. Med. Journal.*, May 12, 1883), Dr. Pavy advanced some views that are so striking as to be well worthy of consideration.

He notes that glucose, cane-sugar and starch, are, in health, all converted by the ferments of the alimentary canal into maltose, which, in turn, is converted in the liver into starch.

It can be demonstrated by experiment, that when the liver is supplied with blood that contains an excess of oxygen, that is not thoroughly venous, a reverse action takes place and starch is converted into sugar.

Dr. Pavy supposes that owing to some lesion of the vaso-motor nervous system, the blood is allowed to circulate abnormally fast through certain areas of the organs which make the chyle, and that thus the portal blood, owing to the hurried circulation which takes place in certain parts, comes to contain too much oxygen.

A valuable coincidence was, that at the same meeting Dr. Dickinson said that he looked to a dilated condition of the blood-vessels in the organs as an important factor in the production of diabetes.

This theory is a very ingenious one, and seems to borrow additional weight from the rather numerous reported cases of diabetes in which ergot has proved beneficial; but does it go far enough?

It accounts for the sugar in the urine, and the hepatic derangement may account for the emaciation and loss of strength; but what accounts for the thirst and the large quantities of urine voided?

What we want is, first to determine whether this theory will stand, and then to inquire into the location and nature of the lesion of the vaso-motor system.

The London Pathological Society has appointed a committee to further investigate the matter.

ANGINA PECTORIS.

Angina pectoris being an affection which is so calculated to tax the equilibrium of a physician when called to a severe case, it is well to have constantly in mind the more important points concerning it. A very interesting lecture on the subject, by Professor Germain Sée, is published in the *N. Y. Med. Jour.*, May 26, 1883.

He considers that angina from tobacco is rare, and when it does occur, abstinence from the weed suffices to cure it; but, on the contrary, alcoholic angina does not yield to suppression of the cause since it is evidence that endarteritis of the coronary vessels as well as degenerations or sclerosis of the myocardium exists.

He states that the etiological treatment is unsatisfactory, and generally unsuccessful, and that the best we can do is to treat the paroxysms, and endeavor to prevent their return.

To meet the first indication, his sheet-anchors are morphia, hypodermically, and nitrite of amyl. He has used nitro-glycerine (one or two drops of a one per cent. solution) with success.

In the intervals of the attacks, he relies upon bromide of potassium if the patient is excitable, and digitalis when the angina results from cardiac atony or degeneration.

SELF-LIMITATION OF CERTAIN DISEASES WHICH ORDINARILY PROVE FATAL.

Drs. T. Gaillard Thomas, B. W. McCready, and A. C. Post had considerable to say on this subject before a recent meeting of the New York Medical and Surgical Society.

They regaled the members with interesting histories of cancers and consumptions in which they had made the gloomiest prognostications, and the patients recovered.

It seems strange that these distinguished gentlemen should deem it worth while to consume the time of the Society in reminding us that *prognosis* is not quite yet an *exact* science.

We have but little fear of honest contradiction, when we say that were every physician to make a memorandum of his prognosis in every case and compare it with final results, we would find ourselves mistaken as often as we would be correct.

We do not mean to belittle the value of prognosis, but we do think that our prognostic signposts are very far from accurate.

THE UTILIZATION OF SEWAGE.

Now that they have succeeded in converting the Thames into a sewer, the people of London are

commencing to think "what they are going to do about it."

Sir Joseph Bazalgate has suggested that works should be undertaken for emptying the sewage of London into the German Ocean, at a cost of \$30,000,000.

This proposition has been very wisely rejected and it is now under consideration to devise some means of converting the sewage of London into manure.

It is estimated that the annual output would realize 650,000 tons of excellent manure, which would materially reduce the expense of inaugurating such a system.

This plan is now in successful operation in portions of France.

It would be well for our cities and towns that are not satisfied (and very few of them ought or have any right to be) with their present method of disposing of sewage, to seriously consider this matter.

PNEUMATIC DRAINAGE.

In our issue of October 14, 1882, we made mention of the pneumatic system of drainage, which was being tried in a quarter of Paris.

It consists in the removal, by suction, of the refuse to a safe distance from the city, where it is converted into manure.

We have now the pleasure of reporting that it has led to such remarkable results in the decline of typhoid fever that it is to be extended to other quarters of the city.

NOTES AND COMMENTS.

A Case of Cystocele Complicating Labor.

Dr. John H. Whitham, L. R. C. P. Ed. of Harworth writes, in the *Brit. Med. Jour.*, May 5, 1883:

On January 10th, a patient of mine, who was pregnant, complained to me that she had "bearing-down pains" in the lower part of her body, and that she thought something had given way. I made a digital examination, and found a tumor protruding through the vulva. I could pass my finger behind it, and could recognize the os uteri high up and looking backwards; but anteriorly the tumor was attached. I concluded that it was

a case of cystocele, and ordered my patient to preserve the recumbent posture, making frequent use of the catheter myself, to prevent accumulation and decomposition of urine. The case went on without any inflammatory symptoms until labor set in on the 29th ultimo. Early in the labor the bladder and rectum were emptied. As the patient had a very roomy pelvis, I found that at first I could replace the tumor and hold it up above the pubes by means of two fingers; but as the pains became more intense, I was obliged to withdraw my fingers, and, in doing so, the bladder followed them. I then consulted with Dr. Dobie, of Keighley, and the result was that I gave the patient a full dose of ergot, placed her in the knee-elbow position, replaced the tumor, and held it in position until the next pain brought down the head well into the pelvis. After this, there was no further trouble; the case was quickly and easily terminated without further complication.

I have reported this case, not because any extraordinary treatment is adopted, but because I had to deal with a complication which is apparently rare, since I have fruitlessly consulted on this point several well-known midwifery books.

Imperforate Hymen Persistent in Labor.

Mr. H. Grey Edwards, B. A., M. B., B. Ch., of Bangor, writes as follows in the *Brit. Med. Jour.*, May 5, 1883:

At 11 p. m., April 25, 1883, I was called to see S. O., primipara, aged 32, said to have been in labor since Monday morning, the 23d ultimo. I found the patient suffering from severe "pains." On digital examination, I was somewhat surprised to find that the orifice of the vagina was completely closed by a tough membrane. Anteriorly, it was comparatively thin, and attached to the edge of the vaginal orifice, whence it sloped gradually backwards, until, at the posterior wall, it was attached an inch and a half from the orifice. Here it was very thick, and gave the same sensation to the finger as the walls of the vagina itself. The foetal head could be easily felt through the tissue, which was perfectly lax, resisting all efforts at rupture with my finger.

Having decided to give the uterus time to do its best, I left, calling again at 4 a. m.; but, though the pains had been strong and frequent, things were much in the same condition. By sawing with my nail at the thinnest part, I eventually got the end of my finger in, and tore the hymen by drawing the finger backwards, until about halfway across, but I could not manage it further.

I then waited an hour, in the hope that the remaining half would not be sufficient obstruction to delivery; but, "pains" becoming short and slight, I put on a forceps, and delivered without difficulty. The patient is going on satisfactorily.

I have reported this case under the belief that such a tough condition of hymen is most unusual.

It is medico-legally interesting, that one single act of copulation, in spite of the seeming difficulties of the case, sufficed for impregnation.

Salicin in Rheumatism.

Salicin is the natural product of the willow root, while salicylic acid is the artificial phenol derivative. Dr. Quinlan says that while the latter will sometimes sicken even in moderate doses, almost any quantity of the former can be given, and in the *Lancet*, May 5, 1883, he records two cases of acute rheumatism rapidly cured by its use. He advises it in large and frequently-repeated doses. One of his cases took eighty grains in one dose, daily, for three days without any bad effect. Salicin in very large doses is most easily taken by stirring it into a hock glass of milk, which the patient rapidly swallows before it has time to settle down from its suspension. It may also be taken in wafer paper, or even in water, but in this case the bitter flavor is felt. It should always be taken on an empty stomach; after food it often occasions nausea and tinnitus. Its value in acute rheumatism cannot be over-estimated, and should the physician get hold of the case early he will likely be able to conquer it before there is time for cardiac complication, so apt to leave enduring mischief behind it. Finally, when the rheumatic sufferer convalesces the salicin should not be dropped too suddenly. For a week it should be given in full doses morning and evening, and for a fortnight once daily; otherwise a relapse may supervene. A notable feature in the salicin treatment is its tonic effect in promoting a steady and rapid recovery of strength and vigor during convalescence.

It is very cheap, selling in England, at retail, for less than twenty-five cents per ounce.

Acute Articular Rheumatism in Childhood, with a Peculiar Complication.

In a girl, æt. 12, suffering from regurgitation of the mitral valve, there were noticed on some joints, especially at the places of insertions of sinews, small, diffuse, painless spots of thickening; they could be felt especially well on both knee-joints, over the attachment of the quadriceps on the

upper edge of the patella and in both wrists above the styloid process. After the patient had passed through an attack of acute articular rheumatism, these spots of thickening had changed to moderately resisting and somewhat sensitive nodules of the size of a split pea. Besides the places above mentioned, these peculiar appearances were observed also on both external malleoli, on the right elbow above the olecranon, near the spina ileum sep-post on either side, and on the right shoulder-joint below the attachment of the clavicle. The *post mortem* examination revealed them as fibrous nodules with cartilaginous parts; some even showed a bony texture, and some chalky deposits, they evidently being different stages of the same process.

The case was observed in Henoch's clinic (*Berl. klin. Wochens.*, 1883, N. 11), and in a second case also treated there, these nodules were absorbed and totally disappeared. The second case was also that of a twelve-year-old girl.

Antiseptic Inhalations in Phthisis.

Viewing phthisis as caused by micro-organisms and knowing that certain antiseptic drugs have the power of destroying the vitality of organisms, the antiseptic treatment of phthisis would seem theoretically to possess much to recommend it. Dr. Arthur Hill Hassall has instituted some observations on the subject and his results (*Lancet*, May 5, 1883,) are negative. He used carbolic acid, creasote, thymol, and iodine. With the exception of iodine, only a very small amount of the drug was volatilized, the amount found in the vessel at the end of the observation being very nearly equal to that originally used, while the iodine was converted during the process of inhalation into the iodide, and thus lost its antiseptic properties. These results argue against attempting to volatilize these articles, but they do not prove that the insufflation of powders, such as iodoform, may not have a beneficial effect. This is a field of therapeutics but little cultivated as yet.

Poisoning by Salicylate of Soda.

In the *British Medical Journal*, May 5, 1883, Dr. Frank Ogston reports the case of a man who took fifteen grains of salicylate of soda for rheumatism. One hour and a half afterwards he fell asleep, and shortly afterwards became comatose, with contracted pupils; respiration 12, pulse 45, and temperature 98.5. He continued in this condition for sixteen hours, when he died. The remaining powders, upon examination, were found to contain nothing but salicylate of soda. Upon *post mortem*,

no organic lesions of sufficient gravity to account for death could be found, so that Dr. Ogston concluded that death was due to the salicylate. This opinion was doubted by many who heard the report of the case, but no one was able to absolutely disprove it. Such poisonous properties are not usually attributed to this drug, and it would be interesting to know more about the influence of idiosyncrasy in this regard.

The Picric Acid Test for Albumen.

Some physicians having failed to detect albumen with picric acid, when it was to be found with other tests, causes Dr. George Johnson to call attention to the erroneous manner in which they used it, and to enunciate the following caution in the *British Medical Journal*, May 5, 1883:

It should always be borne in mind that, in testing for albumen, the *picric acid must be in excess*. A few drops of a saturated solution of picric acid in a highly albuminous specimen will form a coagulum, which is quickly redissolved; and this explains the fact that one of my correspondents, who poured the picric acid solution on the surface of highly albuminous urine, got an indication of albumen, which soon disappeared. When urine contains much albumen, it should be mixed with its own volume of the picric acid solution; and in testing a fresh specimen, it is better to begin by adding an equal volume of the test liquid.

Treatment of Chordee.

The following prescription has very often been effectual in the hands of M. Mauriac, in the Hospital des Veneriens:

R. Syr. digitalis (fr. cod.),
Syr. morphiæ (fr. cod.), āā ̄ iss.
Kalii bromid, ʒ v.

M. Tablespoonful every evening at bedtime.

Or a suppository as follows:

R. Chloral hydrat., gr. xx.
Ol. theobromæ, q. s. M.

For one suppository.

Or the following injection, recommended by Camillard:

R. Kalii bromid., ʒ iss.
Tr. opii, ss.
Glycerinæ, ss.
Aq. distill., ʒ v. M.
S. 4 injections daily.

Methods of Administering Resorcin.

M. Andeer gives the following prescriptions for the administration of resorcin, which has been experimented with as an antipyretic and antiseptic.

tic in febrile conditions, especially in stomatitis, infantile cholera and diphtheria :

R. Resorcin, gr. vij.—gr. xlv.
Syr. aurantii cort., ℥j.
Aquæ destil., ℥iij. M.

S. A tablespoonful of this potion every two hours.

To make an emulsion, seven grains of resorcin may be made up with five drachms of sweet almonds and water to three fluid ounces, and a tablespoonful administered every two hours.

In powder, resorcin may be given in doses of two or four grains in syrup or alone in cachets.

Carbolic Acid in Piles and Fistulæ.

The fact that there is a growing tendency among physicians to the belief that carbolic acid injected into the pile tumors will radically cure and entirely remove them, and that it amounts almost to a specific in fistula, has induced Dr. A. B. Allen, of Jerseyville, Ill., to write to the *Peoria Medical Monthly* for May, 1883, condemning this practice. In conclusion, he says :

"I have met over one hundred cases that had been treated by some one of the above methods before coming to me. The universal verdict has been that it is very painful, and I am certain ineffectual, and a large proportion of them certainly very much debilitated, either from the therapeutical effects of the drug, or from the excruciating pain they had undergone."

The Treatment of Croup.

Dr. Charles J. Fahie writes to the *Brit. Med. Jour.*, May 12, 1883, that out of ten cases of croup treated as follows he did not lose one. He provides that the case must be seen early. A hot bath, a hot poultice of burnt salt to the throat externally, a mustard emetic, and a dose (to be regulated according to the age of the child) of the following mixture every two hours: Tartar emetic, liquor ammoniæ acetatis, and mistura citratis potassæ, to six ounces. The citrate of potash mixture can be made by saturating bicarbonate of potash with citric acid.

Such success raises a question as to the correctness of Dr. Fahie's diagnosis, about which he says nothing.

Solution in Otagia.

The following solution has been highly recommended in ordinary earache, unaccompanied by suppuration or rupture of the tympanum :

R.—Atropiæ sulphat, 20 centigrams.
Aquæ destillat., 25 grams. M.

Four or five drops of this solution may be dropped into the ear, and left there for ten or fifteen minutes, then the cavity of the external ear should be dried with a small pad of cotton wool.

This may be repeated several times, and is given as a heroic remedy in ear troubles. This solution is of course intended for the adult, and should be diluted at least with four times the quantity of water for children under three years of age.

The Nature of Puerperal Fever.

Dr. William Alexander, of Liverpool, believes that puerperal fever is in reality one of the eruptive fevers that has induced septicæmia. Scarlatina, typhus, erysipelas, or typhoid fever appearing in a puerperal woman will often rapidly interfere with the normal puerperal uterine conditions, and produce a disease whose origin is the poison of an eruptive or continued fever, and whose course is that of a modified septicæmia.

He has been contributing some valuable papers on this subject to the *Med. Times and Gaz.* (May 5-12, 1883.)

Swallowing of Shot and Insufflation in the Treatment of Ileus.

From the *London Med. Record*, May 15, 1883, we learn that in three cases (*Gazz. Med. Ital. Lomb.*, February 10, 1883), with well-marked symptoms of invagination of the bowel, obstinate constipation, stercoraceous vomiting, pain, etc., Dr. Pedrini, after other remedies had failed to relieve, made the patient swallow five or six bullets and two kilogrammes of No. 3 shot, at the same time using prolonged and repeated insufflation of air by the rectum. In each case the success of this treatment was complete, relief being quickly obtained, and the patient making a good recovery.

Is Distilled Water in all Cases the Best Vehicle for Eye Lotions?

In the *Practitioner* for May, 1883, Dr. Paul M. Chapman claims that it is not, saying: "I have tried the experiment on myself and on many of my friends, and the answer is always the same, viz., that the introduction of distilled water into the eye is attended with much discomfort and smarting, while with normal saline there is no noticeable effect whatever.

"The practical deduction is this, which I have also verified, that the addition of 2½ grains of chloride of sodium to the ounce of distilled water renders any lotion intended to be of a soothing character much more beneficial."

Ergot in Diabetes Insipidus.

The success which has attended this treatment in the hands of Dr. T. Hammond Williams (*Lancet*, May 12, 1883), would seem to lend some coloring to Dr. Pavy's view of the etiology of the disease (described in our editorial on the subject, p. 666). Two drachms of the fluid extract thrice daily reduced the quantity of urine more than one-half. The cases passed from observation, so that, unfortunately, the permanency of the good results cannot be told.

Insanity in a Child.

The *Alienist and Neurologist*, April, 1883, says that a six years ten months' old child is reported by Berner (*Norsk Magazin for Lægevidenkaaben*, Bund XII, Hefte 3) to have been attacked by melancholia. The patient was desirous of solitude, very restless and unquiet in slumber, and had hallucinations of sight and hearing. There were at times paroxysms of markedly painful depression. Hereditary history was uncertain, and the patient recovered in a month.

Sub-mucous Chloroform Injections in Toothache.

Gaillard's Med. Jour., May 19, 1883, says that Dr. Guillot (*Progrès Médical*, March 24, 1883), claims to have had very good results in the treatment of toothache from the injection of chloroform beneath the mucous membrane of the gums. The effects are more immediate and lasting than those of morphine. There have been no resultant abscesses or inflammations.

Snake Bites.

In the course of discussion on the "Poison of the Viper" in the *Lancet*, April 28, 1883, Sir Joseph Fayrer, commenting on the excision of the bitten part, says: "In cutting out the part it is necessary to remove all the tissues stained the peculiar red tint caused by snake bites."

CORRESPONDENCE.**Cases of Poisoning.**

EDS. MED. AND SURG. REPORTER:—

Passaic county has its courts a trifle burdened just at present in disposing of cases of poisoning. The second trial of "Aunt Sally" Story for causing the death of Mrs. Feest by giving her strychnia, which she told her was quinine, has just ended in her conviction for manslaughter. The prisoner has a bad record, having been accused of poisoning a neighbor's dog; of threats of poisoning human beings, and of one attempt on human life before the present. The poison had been in the house of the accused for two or three years, and had been seen by two neighbors at different times, Mrs. Story explaining what it

was, and that it was intended for rats and mice. It was wrapped in white paper, and enclosed in an envelope marked "Poison" with blue pencil. Not long prior to the poisoning, she showed the white paper and inclosure to the physician who sometimes attended her, asking him, "Is this marked quinine?" The doctor said not. On tasting it, he said, "It tastes like quinine, but you had better not use it, on account of uncertainty."

Not long subsequently the deceased was drawing water from Mrs. Story's well, and complaining of having the chills, which her physician failed to give quinine enough to cure effectually. Thereupon, Mrs. Story presented her with the powder, saying that it was quinine, and would help her. This was on the evening of September 14th last. The next morning at six o'clock the victim swallowed it, and in fifteen minutes died, with the spasms peculiar to strychnine poisoning.

Mrs. Story, who lived hard by, was informed of the death once or oftener, before 8 a. m., yet two hours later she affected surprise at hearing of it, weeping and making ado about her loss, etc. At the coroner's investigation, she swore that the only strychnine she had had in the house for years was entirely used in destroying minks. This made it very difficult for her to account for its presence in her house, and its accidental (?) substitution for quinine. She has been in prison for eight months, a former trial having resulted in a disagreement of the jury. The present trial attracted few spectators, though it has been distinguished for the legal acumen and ability with which it has been conducted, and for the fairness and perspicuity of the judge's charge. The verdict is universally regarded as just and proper; though the "recommendation to the mercy of the court," secured a sentence generally deemed inadequate.

The trial has thrown a strong light on the lack of care employed in dispensing deadly drugs. A clerk from a leading drug store testified that poison was sold without weighing, a guess being made at the amount to be delivered for a given purpose; that it was enclosed in white wrapping paper, and placed in an envelope, which was marked "Poison" with any marking material most convenient. There was nothing in the color of any of the enveloping materials to indicate the dangerous nature of the contained drug; and no record was kept of the name of the purchaser. The judge, who elicited many of these points, remarked that it would be necessary to be a little more careful, as the late legislature had passed an act bearing upon this matter.

The second case of poisoning includes the family of Robert McLaren, consisting of himself, wife, and three children, together with a boarder named William Black. They were all taken with extreme epigastric pains, vomitings, and some diarrhoea soon after eating the mid-day meal, on Tuesday, May 23d. McLaren is employed in the Rogers Locomotive Works, and in common with some fellow-workmen has a physician to attend by the month, who saw the McLarens soon after the occurrence of the violent symptoms, and subsequently on the evening of the same day. Becoming otherwise engaged, he gave no further attendance until the announcement of the death of John

McLaren, sometime in the morning of the 25th. A second physician having been summoned on the afternoon of the 24th, found the youngest of the McLarens, aged six, affected as above described, and pulseless; Robert McLaren, the father, in a fainting condition; and William Black in a collapse, pulseless, and in a cold sweat. The vomiting of the last had been very frequent and violent, and attended with cramps in the stomach and legs. He complained of a burning in the rectum as if hot water were passing his bowels. All were drinking large quantities of water, which was presently rejected. The pulse, in those in which it was appreciable, was quick. Measures were taken to check the vomiting and support the flagging powers of life, which succeeded in those in whom the pulse had not ceased at the wrist. William Black and John McLaren, exhibiting these symptoms, died between two and three o'clock of the morning of the 25th, a little over a day and a half from the period of attack.

The perpetrator is unknown, but some suspicion has rested upon Wm. Black, who was separated from his wife and other friends; and, having been an inmate of the poor-house, was supposed to be tired of life; he was also said to be at variance with the mistress of the house.

The autopsies, as reported by the daily papers, present some points of interest to the profession. In Black's case, it consisted of an examination of part of the abdominal viscera, and a superficial examination of the lungs. In the case of the child, the viscera of the chest and abdomen were examined, with the exception of the stomach, which was removed but not opened, being reserved entirely for the inspection of the analytical chemist, should one be employed in the case. This is said to be in accordance with the preference of Prof. Doremus in cases of volatile poisons. The autopsies were held in the evening, a circumstance condemned by the very high authority of Virchow.

E. T. BLACKWELL, M. D.

Paterson, N. J., June, 1883.

NEWS AND MISCELLANY.

American Surgical Association.

(Concluded from page 647.)

THIRD DAY.

Dr. S. W. Gross, of Philadelphia, reported

A CASE OF NEPHRECTOMY FOR MEDULLARY CARCINOMA AND PARTIAL CHOLEO-CYSTECTOMY FOR CALCULUS IN THE SAME SUBJECT.

Dr. J. Ewing Mears, of Philadelphia, followed with a paper entitled

CLOSURE OF THE JAWS AND ITS TREATMENT.

Dr. Vanderveer, of Albany, N. Y., now read his paper on

REMOVAL OF MECKEL'S GANGLION FOR THE RELIEF OF TRIFACIAL NEURALGIA.

Dr. J. M. Barton exhibited a splint which he had used for some years for synovitis of the wrist joint.

Dr. David Prince, of Jacksonville, Ill., gave a description of his *rectal obturator*.

Dr. Campbell, of Georgia, gave a description of several cases of

STRICTURE OF THE OESOPHAGUS WITH REMARKS ON TREATMENT.

Dr. Campbell presented some apparatus for fixation of the elbow-joint, devised by Dr. Coleman, of Augusta.

Dr. Bontecue advocated irrigation in cases of cystitis.

OFFICERS FOR 1883-84.

President—Dr. E. M. Moore, Rochester, New York.

First Vice-President—Dr. W. W. Dawson, Cincinnati.

Second Vice-President—Dr. C. H. Mastin, Mobile.

Secretary—Dr. J. R. Weist, Richmond, Indiana.

Treasurer—Dr. J. H. Packard, Philadelphia.

Recorder—Dr. J. Ewing Mears, Philadelphia.

Member of Council—Dr. P. S. Connor, Cincinnati.

The next place of meeting is to be Washington, D. C., on the Wednesday before the meeting of the American Medical Association.

American Medical Association.

The American Medical Association met in annual session in Cleveland, and continued in session June 5, 6, 7 and 8. The address of welcome was delivered by General Edward S. Meyer.

The President, the veteran Dr. John L. Atlee, of Lancaster, then delivered his address, which consisted in a most graphic and interesting description of the condition of our profession sixty-five years ago, when he was a student; it was replete with reminiscences of the distinguished teachers of those by-gone days, and was listened to with great attention.

BUSINESS TRANSACTED.

Drs. J. S. Billings, U. S. A., presented a communication from the President of the British Medical Association and Dr. Mahomed, inviting coöperation with the committee of the Association on the

COLLECTIVE INVESTIGATION OF DISEASE.

Dr. H. D. Didama, of New York, presented a communication from Dr. Tyndale, of New York, containing a petition to Congress, the Secretary of War, and the Signal Service Department, requesting that a committee of five professional gentlemen be appointed to establish

CLIMATIC OBSERVATIONS

at the general health resorts and watering-places, and to collect data in regard to the sanitary value of the localities in regard to pulmonary diseases. Adopted.

Prof. S. D. Gross, of Philadelphia, read a communication signed by himself, Dr. Austin Flint, Jr., and Dr. Oliver Wendell Holmes urging upon the Association the importance of petitioning Congress to provide a suitable fire proof building for the Army Medical Museum and Library.

Dr. H. A. Johnson, of Chicago, then offered a series of resolutions to this effect, in which Congress is asked to make an annual appropriation of \$10,000 for the purchase of books.

The report of the Trustees of the new Journal was read, which shows that they have received

pledges of subscription to the number of 2,500. The journal will be published in Chicago by A. D. Newell & Co. Dr. N. S. Davis, of the same city, will be the editor, and the first number will be issued soon after July 1. The minutes of the meetings will hereafter be published in a small volume, the papers appearing in the Association Journal.

A resolution was offered by Dr. Batchelor and adopted, that the President shall appoint one or more members from each State, whose duty it shall be to secure by petition or otherwise the passage in their respective States of more stringent laws respecting the sale of poisons.

Dr. S. D. Gross, of Philadelphia, offered a resolution that in recognition of the necessity of trained nurses, and the benefit that has arisen from the establishment of training-schools for nurses in large cities, the Association recommends the establishment of similar schools in every county of each State, instruction to be given gratuitously, or at rates which do not exclude the poor from their benefits.

Dr. Walter Hay, of Illinois, moved that a special

SECTION OF PSYCHOLOGICAL MEDICINE be organized. Laid over for one year in accordance with the rules.

The report of the Standing Committee on

ATMOSPHERIC CONDITIONS AND THEIR RELATIONS TO THE PREVALENCE OF DISEASES,

was presented by Dr. N. S. Davis, Chairman. He stated that the work of the Committee was begun as quickly as possible after the last meeting. Observers had been appointed in twelve different parts of the United States, who received instructions to take accurate observations, during the day and night of every day in the year, as well as to note the presence of any organic matter in the air. He then spoke of the necessity of continuing the observations through several years, and closed with a statement of the finances of the Committee.

Dr. S. Pollak, of Missouri, offered a resolution on behalf of the St. Louis Medical Society, to the effect that whereas many of the provisions of the present Code of Ethics are obsolete, and that early revision is necessary, and that no society except the American Medical Association has any power to alter the present Code, but only to ask for its revision; therefore, that the American Medical Association be respectfully requested to appoint a committee of one member from each State, for the purpose of taking into consideration the propriety of revision of the Code of Ethics of the American Medical Association, and report thereon at the meeting of 1884. That this committee be authorized to propose a Code of Ethics, which, in their opinion, will meet the wishes of the profession, and to submit the same at the next annual meeting.

It was immediately moved and seconded, by more than a hundred voices, that these resolutions be laid upon the table, and the motion was carried almost unanimously, amidst loud applause.

The Nominating Committee reported the following nominations of members of the

BOARD OF TRUSTEES OF THE JOURNAL,

to fill the positions occupied by those whose term

expires this year, and one to fill the vacancy occasioned by the resignation of Dr. N. S. Davis: A. Garcelon, of Maine; J. O. Hooper, of Arkansas; L. S. McMurtry, of Kentucky; and J. H. Hollister, of Illinois.

THE COMMITTEE OF PUBLICATION

reported that an index of all the volumes of Transactions was now in preparation, of which 1,500 copies would be issued, at a cost of \$500, and would be sold to members at one dollar per volume. The report was received and adopted.

THE COMMITTEE ON NOMINATIONS

presented the following report, which was adopted: President—Austin Flint, Sr., M. D., of New York.

Vice-Presidents—R. A. Kinloch, M. D., of Charleston, S. C.;

T. B. Lester, M. D., of Kansas City, Mo.;

A. L. Gihon, M. D., of U. S. Navy; and

S. C. Gordon, M. D., of Portland, Maine.

Treasurer—R. J. Dunglison, M. D., of Pa.

Librarian—C. H. A. Kleinschmidt, M. D., of Washington, D. C.

Place and Time of Meeting—Washington, on the first Tuesday in May, 1884.

Chairman of Committee on Arrangements, A. Y. P. Garnett, M. D., of Washington.

Assistant Secretary, D. W. Prentiss, M. D., of Washington.

CHAIRMEN OF SECTIONS.

Practice of Medicine—J. V. Shoemaker, of Pennsylvania.

Obstetrics—T. A. Reamy, of Cincinnati.

Surgery—C. T. Parks, of Illinois.

Ophthalmology—J. J. Chisolm, of Baltimore.

Diseases of Children—Wm. Lee, of Indiana.

State Medicine—J. D. Roberts, of Tennessee.

Oral Surgery—T. W. Brophy, of Illinois.

The following were appointed a committee on surgical service aboard steamers and other ocean vessels: Dr. A. N. Bell, of New York; Dr. A. L. Gihon, United States Navy; Dr. J. N. Quimby, New Jersey; Dr. H. O. Marcy, of Massachusetts, and Dr. Henry H. Smith, of Pennsylvania.

ADVANCEMENT IN CREMATION.

Dr. Keller presented the following:

That in the very near future, if not now, cremation will become a sanitary necessity in the large cities and populous districts of the country, and that the question be referred to the section on hygiene, which was done.

Dr. William Bodine and Dr. H. T. Walker were selected as delegates to the Canadian Medical Association meeting.

PAPERS READ.

Dr. Robert D. Murray, U. S. Marine Hospital Service, subject: Yellow Fever.

Dr. Wm. Morrow Beach, Ohio, subject: Milk Sickness.

Dr. W. H. Byford, Chicago, subject: Chronic Intra-Pelvic Inflammation.

Dr. Henry G. Landis, Columbus, Ohio, subject: Post-partum Polypoid Tumors.

Dr. H. O. Marcy, Massachusetts, subject: The Restoration of the Perineum by a New Method.

Dr. R. S. Sutton, Pennsylvania, subject: Enterotomy as a complication in Ovariectomy or Oöphorectomy.

Dr. Reuben A. Vance, Ohio, subject: The Radical Cure of Hernia by a New Method.

Dr. Dudley P. Allen, Ohio, subject: A Comparison of Antiseptic and Non-Antiseptic Methods of Treatment.

Dr. Henry A. Martin, Massachusetts, subject: The Treatment of Synovial Diseases by a New Method.

Dr. Lawrence Turnbull, Philadelphia, subject: Paralysis of the Facial Nerve in Connection with Diseases of the Ear.

Dr. W. C. Jarvis, New York, subject: Tonsillectomy by Ecrasement.

Dr. Carl Seiler, Philadelphia, subject: Action of Nitrate of Silver on the Mucous Membrane of the Throat.

Dr. C. Williams, St. Paul, Minn., subject: Myringitis.

Dr. C. W. Earle, Chicago, subject: Cephalæmatoma in New-born.

Dr. J. H. Hollister, Chicago, subject: The Address in Medicine.

Dr. J. K. Bartlett, Wisconsin, subject: The Address in Obstetrics and Diseases of Women.

Dr. W. F. Peck, Davenport, Iowa, subject: The Address in Surgery.

Dr. Foster Pratt, Kalamazoo, Mich., subject: The Address on State Medicine.

Dr. R. M. Blount, Indiana, subject: Address on Diseases of Children.

Dr. Paul T. Eve, Nashville, Tenn., subject: An Appliance for Keeping the Arm Stationary.

A postal card addressed to the Secretary of the American Medical Association, Dr. Wm. B. Atkinson, No. 1400 Pine street, Philadelphia, will procure the post-office address of any of these gentlemen, and a postal card to any of them will procure a copy of any desired paper; thus freeing our columns from pressure.

Connecticut State Medical Society.

At the recent meeting held in Hartford, May 22d and 23d, the following papers were read:

<i>Author.</i>	<i>Subject.</i>
Dr. W. G. Brownson . . .	President's Address.
" M. H. Henry	Varicocele.
" M. C. White	Micro-spectroscopy.
" W. C. Wile	Extirpation of the Entire Uterus.
" " "	Resection of Hip-joint.
" W. C. Burke, Jr. . .	Removal of Entire Uterus.
" G. L. Porter	Extra-uterine Pregnancy.
" M. C. White	Vesical Calculi.
" George S. Parmelu .	Points in Oral Surgery.
" W. H. Holmes . . .	The Treatment of Pleurisy by Aspiration.
" F. N. Braman . . .	Complications in Labor.
" A. Beardsley . . .	The Treatment of Intermittent Fever.

The Secretary is Dr. S. B. St. John, Hartford, Conn.

Parasites in the Human Body.

We note the following from the *Proceedings of the Med. Soc. of the County of Kings*:

Recent investigations have added greatly to our knowledge of the more highly organized parasites of the helminthoid type. For example, it has

been ascertained beyond doubt that the blood-vessels of a human being capable of performing his daily avocations may contain from 20,000 to 30,000 minute embryo nematoid worms. A physician of Calcutta demonstrated this with regard to persons in that climate. Numbers of individuals so affected suffer from chyluria, or elephantiasis in one or other of its forms; but this is by no means universally the case. Researches have also revealed the curious fact that these teeming multitudes of nematoids lurk in some unknown recesses of the vascular system during the daytime, and that only as night approaches do they wander at large through the vessels generally. Experts assure us that a single drop of blood taken from the prick of a finger at midnight in a person so affected may contain as many as 200 embryo nematoids, while many drops similarly obtained at midday will not reveal a single worm.

Missouri Medical Association.

The following are the officers for the ensuing year.

President—Dr. E. H. Gregory, of St. Louis.

Vice-Presidents—Dr. O. A. Williams, of Morgan county; Dr. John H. Duncan, of Boone county; Dr. J. D. Griffith, of Jackson county; Dr. T. J. Norris, of Macon county; Dr. C. A. Hughes, of St. Louis.

Recording Secretaries—Dr. A. H. Ohmann Dusenil, of St. Louis; Dr. D. V. Wales, of Jasper county.

Corresponding Secretary—Dr. N. F. Essig, of Clinton county.

Treasurer—Dr. C. A. Thompson, of Cole county.

The next meeting of the Association will be at Sedalia.

A Useful Book.

Dr. J. W. McCausland, of Fort Wayne, Ind., pays a deserved compliment to the excellent practical treatise of Dr. F. de Havilland Hall. He writes:

"Why is the work called 'Hall's Differential Diagnosis' not more generally introduced. I think it is far ahead of any other work of its kind. The manner in which the symptoms of kindred diseases are tabulated for convenient comparison renders it at once invaluable, and such I think would be the universal verdict if the book were better known."

Regulating the Practice of Medicine in Minnesota.

A law recently enacted provides that the Faculty of the Medical Department of the Universities of Minnesota shall organize as a Board of Examiners. All persons who practice medicine in the State must present their diplomas to this Board for verification, or if they have no diploma must submit to examination in order to receive a license.

Philadelphia County Medical Society.

At the last meeting of the Philadelphia County Medical Society, held June 13, Dr. W. S. Little read a paper entitled "Condition of the Eyes in Strabismus due to Optical Defects," and Dr. M. Lardesberg read a paper entitled "Stretching the Optic Nerve."

Texas Medical Association.

Officers for the ensuing year :

President—Dr. A. P. Brown, of Jefferson.

Vice-Presidents—Drs. T. H. Nott, of Goliad; J. D. Osborne, of Cleburne; Frank Allen, of Lexington.

Secretary—Dr. W. J. Burt, of Austin.

Treasurer—Dr. J. Larendon, of Houston.

Place and time of next meeting, *Belton*, on the last Tuesday in April, 1884.

To Preserve Milk.

In the *Berlin Klin. Woch.*, 1882, No. 5, Ph. Biebert says that milk allowed to remain at a temperature of 100° in a water bath for two hours, will keep sweet and pure for at least six months. It is important to seal it up before placing it in the water bath. The method known as Becker's, which consists in keeping the bath at 60°, is unsatisfactory, as milk thus treated is preserved for only forty-eight hours.

Therapeutic Improvements—Fehling's Test Tablets.

An exceedingly neat form of these tablets is made by John Wyeth & Bro., Philadelphia. As our readers know, they are used for the ready preparation of a test solution of potassio-cupric tartrate for the purposes of urinary analysis. They will be found very convenient in practice.

Iodia.

The combination under this name—the formula of which is published, and the peculiar merit of which is principally owing to the studious care devoted to obtaining perfectly pure and fresh ingredients—has met with much favor in the profession. We notice Dr. Byford, of Chicago, recommends it highly. It is prepared by Battle & Co., St. Louis.

Tennessee State Medical Society.

The following officers were elected for the ensuing year: President, Dr. A. B. Tadlock, of Knoxville; Vice-Presidents, Dr. A. Morrison, Nashville, and Dr. C. S. Wright, Chattanooga; Secretary, Dr. C. C. Fite; Treasurer, Dr. D. J. Roberts.

The Chicago Medical Society.

The Chicago Medical Society elected the following officers for the current year: Dr. S. W. Graham, President; Dr. R. G. Bogue, First Vice-President; Dr. R. Park, Second Vice-President; Dr. L. H. Montgomery, Secretary, and Dr. E. F. Ingalls, Treasurer.

Items.

—Mr. Edison's patents now number 396; more than were ever before granted to one man.

—For making permanganate of potassium into pills, B. S. Proctor (*Pharm. Jour. and Trans.*) recommends China clay and water. The pills keep well, and disintegrate readily in water, yielding the permanganate unchanged.

—It is stated that the Duke Leopold Torlonia has taken in hand the matter of sanitary arrangements of Rome, and will see to the funds being forthcoming.

—Ten tons of linseed meal are used annually for poultices in one of the largest London (England) hospitals, and the yearly bill for lint foots up to over two thousand dollars.

—Asthma cigarettes, made by impregnating tobacco with fluid extract of grindelia, drying, and rolling up in the usual way, are recommended by the *Boston Journal of Chemistry*.

—When John Hunter first tied the femoral artery for popliteal aneurism, he turned around to Mr. Peile and said: "Now, the absorbents are busy below, like mites in a cheese."

—The cost of cremating seven thousand bodies per annum at Bombay is said to be only \$15,000, or rather less than two dollars and a quarter for each corpse.

—An unmarried woman in France administered a teaspoonful of creasote to her infant with a fatal result. The post-mortem appearances were those of an escharotic poison, and the odor of creasote was marked.

—The curious observation has been made by a French writer that the initials of the five elements (in their French names) which enter chiefly into the constitution of organic matter, namely, Carbone, Hydrogene, Azote, Oxygene, and Soufre, spell CHAOS.

—MM. Paul Hélot, surgeon to the Rouen Hospital, and Q. Trouvé, have devised an electric lamp to be worn on the forehead, in the examination of cavities. The light is very intense, and will last for hours.

—The Crown Prince and Princess of Germany, in accepting a fund collected in Germany on the occasion of their silver wedding, have resolved to devote it to the promotion of the welfare of the people, and especially to the improvement of existing sanitary conditions.

—The Signal Service Office estimates that ships containing at least \$13,000,000 of property, besides many lives, were saved from running into the disastrous cyclone in October by the warning it gave. The money thus saved in one storm would pay the expense of the Service for ten years.

—Professor Blackie considers that we have at the present day made a distinct advance in the art of dining, though he admits there are still "fools and beasts in high places" who are a disgrace to humanity. The Professor does not deny that we have vastly improved on the habits of our ancestors in the matter of post-prandial drinking.

—A German doctor, named Senna, recommends bread made with sea-water as a wonderful remedy against scrofula and disorders resulting from insufficient nourishment. Sea-water ought to stand twelve hours before being used for making dough, in order to free it from impurities. Bread made with it has no unpleasant taste.

—A writer in a German paper states that it is the custom in offices in that country to have a sliced potato on the desk for use as a penwiper, and to clean steel pens. It removes all ink-

crusts, and gives a peculiar smooth flow to the ink. New pens should be passed two or three times through the gas flame to remove the grease with which they are coated. The ink will then flow freely.

—Curran, being at a party at the seat of an Irish nobleman, one of the company, who was a physician, strolled out into the churchyard. Dinner being served up, and the doctor not returned, some of the company were expressing their surprise where he could have gone to. "Oh," says Curran, "he has just stepped out to pay a visit to some of his old patients."

—"New Remedies" says odors can be removed from bottles, jars, etc., by washing them with a mixture of powdered black mustard and warm water. Before using this, all visible remains of the former contents should be removed by scalding, scouring, or by agitating shot or pebbles with water in the vessels. Another method is to rinse them with a solution of permanganate of potassium, accompanied or followed by diluted sulphuric acid. In many cases, a solution of chlorinated lime or chlorinated soda will answer the same purpose.

—A method of signaling by means of electric balloons was recently tried in Paris by MM. Mangin and Baudet. The balloon, made of paper rendered translucent, was about 8 feet in diameter and was filled with pure hydrogen. A Swan lamp was fitted inside, and a light rope, carrying two copper wires, was attached. When the circuit was completed, the whole balloon appeared to be a globe of fire. By switching the current off and on, the Morse code can be spelled out, and thus captive balloons of this kind can be used for signaling purposes.

OBITUARY NOTICES.

DR. DAVID PARSONS HOLTON.

Dr. David Parsons Holton, a well-known gynecologist of New York city, died at his late residence, No. 20 Sutton Place, near East Fifty-ninth street, June 7, in the seventy-second year of his age. Dr. Holton had been gradually failing for several months. He leaves a widow, but no children. Dr. Holton was born in Vermont in 1812, and his early education was received in an academy at Bell's Falls, in that State. When about nineteen years old he was appointed Principal of an academy at Southwick, Mass., where he remained two years. Afterwards he came to New York, and graduated from the Medical School of the University of the City of New York. For two years he practiced medicine in Essex county, N. Y., and then returned to New York city to reside. He is said to have used up an estate valued at more than \$50,000 in benevolent projects.

DR. JAMES LENOX BANKS.

Dr. James Lenox Banks died June 3, at his residence, No. 79 Fifth avenue, New York city. He was born at No. 5 Pearl street, May 11, 1832. Dr. Banks matriculated in 1854 at the College of Physicians and Surgeons. He was graduated from that institution in 1857. He pursued the higher branches of his studies in foreign institu-

tions for two years, and in 1859 began the active practice of his profession in New York city. He was a member of the American Medical Association, the New York State Medical Society, the New York Pathological Society, the New York County Medical Society, the New York Academy of Medicine, and the Medico-Legal Society. He was also consulting physician of the Presbyterian Hospital and of the Presbyterian Home for Aged Women. He was a member of the Boards of Trustees of the College of Physicians and Surgeons and the Lenox Library, a member of the Board of Managers of the American Bible Society, and was a member of the American Geographical and New York Historical Societies.

DR. S. G. WOLCOTT.

Dr. Samuel G. Wolcott, of Utica, N. Y., the distinguished surgeon, member of the State Medical Society, and one of its censors for the middle district, died June 4, at the age of 63 years.

DR. W. R. CLAPP.

Dr. William R. Clapp, ex-Grand Treasurer of the Grand Lodge of F. and A. M., and a prominent man, died at his residence in Trenton, N. J., June 6. He was in his 87th year, and was born in New York City, his father being Dr. Allen Clapp, who, for half a century was librarian of the Pennsylvania Hospital at Philadelphia. He had a stroke of paralysis on May 3. He died in sleep.

MARRIAGES.

CRAMPTON—MARLING.—On Tuesday, June 5, at the Fourteenth Street Presbyterian church, New York, by Rev. F. H. Marling, pastor, Henry E. Crampton, M. D., and Ellen Eliza, daughter of the officiating minister.

HASBROUCK—SEWALL.—On Wednesday, June 6, at Dobb's Ferry, N. Y., by Rev. D. L. Marks, Joseph Hasbrouck, M. D., to Mrs. Ellen M. Sewall, daughter of the officiating clergyman.

MELLUS—JENKS.—On Saturday, June 2, at the residence of the bride's father, by Rev. W. R. Huntington, D. D., of Worcester, Mass., Edward Lindon Mellus, M. D., of Worcester, Mass., and Mary Gardner, daughter of Francis H. Jenks, of this city.

DEATHS.

BANKS.—In New York, on Sunday, June 3, 1883, James Lenox Banks, M. D., aged 51 years.

FUQUA.—At Plano, Collin county, Texas, on May 22, Dr. S. H. Fuqua, a prominent physician.

KARSNER.—At Ocean Grove, June 6, Dr. Charles Karsner, of Germantown, Pa., aged sixty-nine years.

PANCOAST.—At Baltimore, Md., On the morning of June 7, Rebecca A., widow of Joseph Pancoast, M. D.

STROUSS.—At his residence, Amity, Washington county, Pa., on Tuesday, April 24, 1883, S. S. Strauss, M. D., in his 74th year.

STROUSS.—At her residence, Amity, Washington county, Pa., on Wednesday, May 16, 1883, Mrs. A., widow of the late S. S. Strauss, M. D., in her 55th year.

WELLS.—Suddenly, at sea, on the steamship Arizona, on the evening of Friday, April 27, Dr. William Lehman Wells, of this city. Burial at sea.

WOLCOTT.—At his residence, in Utica, on Sunday, June 3, 1883, Samuel Gardner Wolcott, M. D., in the 63d year of his age.

BRASHEAR.—At Akron, Ohio, Sunday, May 27, Catherine Whitacre Brashear, wife of B. B. Brashear, in the 55th year of her age.

JENSEN'S CRYSTAL PEPSIN,

Strictly Inodorously and Tasteless, and Perfectly Soluble in Water without Acid.

(gr. j. of it will dissolve the boiled whites of two or three eggs.)

LECTURE.

RACHITIS AND HEREDITARY SYPHILIS.

BY M. PAUL RÉCLUS.

Prof. Agrégé of the Paris Faculty.

GENTLEMEN: It has been long suspected that a close connection existed between rickets and hereditary syphilis; the idea that one had its origin remote or near from the other, naturally presented itself on account of the strange and sudden appearance of these two diseases, the first, syphilis, preceding the other by about a century and a half.

But what influence has syphilis on the development of this disease?

Must ancestral syphilis be incriminated as a simple cause of dystrophy among the descendants, the same as scrofula, alcoholism, every failing of the organism, and every physiological defect?

The feeble, delicate child, inheriting insufficient vital resistance, will have his articulations affected and his long bones incurvated with the same facility that his feeble constitution, under the same conditions, allows of the development of the tuberculous germ.

Boerhaave and Van Swieten, Portal and Boyer, are among the most illustrious defenders of this doctrine.

Should we, on the contrary, consider rickets as having its origin directly from syphilis, engendered directly by it, and occurring, if not as a necessary, at least, as an habitual accident of this disease; taking its place in the evolution of hereditary syphilis, by the side of specific coryza, alopecia, pemphigus, mucous patches, and visceral

gummata? So that we might conclude by this aphorism, unless there is syphilis among the parents, no child will be affected with rickets.

Such is the thesis proclaimed by M. Parrot, and sustained by him with great ability. We will devote this lecture to the careful examination of his opinions.

Rachitis, affirms M. Parrot, is an accident of hereditary syphilis.

To demonstrate the truth of this opinion, it is not sufficient to show that syphilis has existed among the ancestors of the child; this fact, often very difficult of proof, would simply indicate the influence of syphilis in the development of rachitism, but not the direct descent of the latter from the former.

Because alcoholic subjects frequently engender scrofulous children, it is no proof that scrofula is a manifestation of alcoholism. M. Parrot well understood this, and sought the proofs of hereditary syphilis in the child itself.

Hereditary syphilis, like the acquired form of the disease, is characterized by multiple accidents, which appear simultaneously, or at different periods; they have a certain evolution and may completely disappear, but not without leaving some vestige of their existence.

In order to demonstrate the syphilitic nature of rickets, it is necessary to find on the child, in conjunction with the bone lesions characteristic of rachitis, one or more lesions or signs of old lesions found only in hereditary syphilis.

Such is the method pursued by M. Parrot, who found the subject very imperfectly treated in diverse works on the subject. He succeeded, however, in grouping together a certain number of

lesions, some already well known and others discovered and described by himself. These are: first, accidents of syphilis in full activity, syphilides (mucous patches) about the mouth and anus, alopecia, bullæ, pustules, ulcerations, and gummata, all having their peculiar characteristics and habitual mode of evolution.

Among the alterations of mucous surfaces which have escaped the notice of observers, M. Parrot describes a desquamative affection of the lingual mucous membrane. This consists in white spots over the surface, where the epithelium is thicker than usual, the centre is soon shed, while the lesion continues to spread at the periphery, forming a crescent-shaped lesion with the opening towards the front. Several of these lesions may be found on the surface of the tongue, disappearing to again return without any appreciable cause and at undetermined periods.

In connection with the visceral gummata found at the autopsy, certain forms of cheesy degeneration are found in other organs, particularly, according to the researches of MM. Parrot and Hutinel, in the testicle, which should always be carefully examined, when there is any suspicion of the existence of hereditary syphilis.

These gummata, also, though often found only at the autopsy, are of great importance in demonstrating the connection between rachitism and syphilis.

This is not all. M. Parrot asserts that he can recognize, by certain indelible stigmata, the vestiges of former syphilis; the disease has proceeded through its diverse periods and is finally cured, but not without leaving traces of its passage; so that an experienced observer may reconstitute the history of the malady, its gravity and even the period of duration of the different accidents. These lesions, which affect the external integument and the teeth, are of very great importance in the elucidation of the question at present before us.

Transmitted syphilis, like the acquired disease, often leaves after it cutaneous cicatrices, of which the situation alone reveals the origin.

These marks are always found at certain points, particularly those oftenest occupied by bullæ, pustules and ulcerations of diathetic origin. They are met with on the lips, to the right or left of the median line, or about the commissures. But they appear oftenest towards the lower extremity of the body, at the sacro-coccygeal region, about the anus, and over the internal surface of the thighs.

These stigmata vary, according to their duration and the gravity of the accidents, which pri-

marily produced them. At first they have a red, purplish coloration; later on they become of a pearly-white tinge, and are surrounded by a pigmented zone.

When they result from bullæ or superficial ulcerations, they leave a circular mark of no very great depth, and hardly noticeable. When the lesions have been caused by gummata, a sort of cup-shaped depression is found, showing the loss of substance on the evacuation of the mass.

The dental alterations are more rarely observed, but furnish important evidence when they exist. For syphilis cannot attack the teeth in the adult.

When the ivory and enamel have been completely formed syphilis cannot attack them. The lesion is produced during the period of evolution of the follicle. As, on the other hand, the teeth of the first and second dentition appear in the jaw, and are developed at certain limited and well-known periods, it is possible, by the simple examination of one of the affected teeth, to form an opinion regarding the exact period when the individual suffered from the disease. It will then be necessary to observe if the tooth affected belongs to the first or second dentition; whether the lesion is found on one of the incisors, on a small or large molar, and also the height of the marks on the crown of the tooth. It is from the information thus derived that a close opinion may be formed as to the period the individual suffered from the disease.

These dental alterations, first noticed at the commencement of the last century, by Fauchard, have been well studied by Hutchinson, Tames, Broca, Magitot, Rattier, and by M. Parrot, in the remarkable articles published in the *Gazette des Hôpitaux*.

He describes, under the general designation of atrophy, five forms of alteration; cup-shaped or cupuli-form, sulciform, cuspidian, hatchet-shaped (*en hache*) and Hutchinson's atrophy.

M. Magitot prefers the designation erosion to that of atrophy, and distinguishes several varieties; first a simple notching of the free border of the incisors, small elevations on the triturating surface of the molar teeth (erosion *en mamelon*), congenital absence of the enamel, finally complete erosion of the crown of certain teeth.

These alterations, several varieties sometimes being found on the same tooth, are symmetrical; they attack the two corresponding teeth in the same jaw, and have ordinarily the same seat, form, and depth in both teeth. If two ridges are found on the right canine of the lower jaw, the left canine of the same jaw will present the same

alterations. It is then on homologous points of the same jaw that the diathesis leaves its marks, which permits us to conclude, from the seat and extent of the dental lesion, the precise period when their pathological cause attacked the system, and the more or less marked intensity of the attack.

M. Parrot attributes these alterations to syphilis. They may then be added to the lesions we have already mentioned, and in conjunction with the maculæ patches, bullæ ulcerations, gummata and peculiar alterations of the lingual mucous membrane which characterize syphilis in full activity, we will have the cicatrices of the external integument and mucous membranes, and the atrophic alteration of the teeth as signs that the malady formerly existed. It is thus that M. Parrot solves the problem and considers himself justified in affirming the existence of hereditary syphilis when he discovers any one of the signs enumerated.

The affection of the bones, which by a series of progressive changes leads to rickets, coincides almost constantly with the lesions of syphilis in activity, or with vestiges of the former existence of the malady.

Hence, says M. Parrot, hereditary syphilis must be considered as the immediate cause of rickets.

Rachitis is a systematic lesion affecting the bones at certain determined points, the same for homologous bones and the alterations attacking one rib, or the humerus, or tibia of one side, are found also on the corresponding rib, humerus, or tibia of the other side of the body. Rachitis is also a "chronologic" malady, with distinct types, corresponding invariably to certain periods of the disease; the first type appears at the end of the intra-uterine existence, and may continue during the first five or six months of life. After this term, the second type is developed. The third type, which, according to M. Parrot, differs in no degree from ordinary rickets, very seldom supervenes before the second year. The disease may go through these three periods, but in many cases it first appears in the second or third type.

The first type is characterized particularly by the presence of hard osteophytes, which appear in new layers of bone tissue, deposited about the long and flat bones, particularly towards the lower half of the humerus and the internal surface of the tibia; often they appear on the cranial bones at the junction of the frontal with the two parietal bones, causing the singular deformation

known under the designation, "natiform skull."

These masses differ from normal bone by a peculiar coloration, and by the direction of the trabecules, which are perpendicular to the axis of the diaphysis. At the same time in many cases a chalky layer is met with, not far from the epiphysis; it is friable, and not more than one or two millimetres in thickness; it has been called by M. Parrot chondro-calcareous, "because it is nothing more than cartilaginous tissue infiltrated with lime salts."

The second type, that of gelatiniform atrophy, presents, together with the alterations found in the preceding type, osteophytes and chondro-calcareous layer, certain circumscribed portions, where the bone is replaced by a soft tissue, filled with a substance "watery, transparent, of different shades, often yellow, much resembling a mass of gelatine."

At these points the bone offers no resistance and breaks easily; juxta-epiphysary fractures are observed, and the limbs are so powerless that pseudo-paralysis of syphilitic nature is often suspected.

Finally, the third type, that of spongoid tissue corresponds to ordinary rickets. The chondroid layer of the conjugal cartilage is very thick, and is penetrated by a soft, vascular tissue of new formation called spongoid tissue by Jules Guerin; these exuberant masses raise about the joint numerous osteophytes, of which the volume and flexibility explain the peculiar appearance of the extremities, the incurvations of the diaphyses, and the frequent occurrence of fracture. The bones are in part decalcified and almost wholly composed of masses of medullary elements.

These three types may succeed each other; they pass one to the other by insensible transitions.

It is not rare to meet with traces of the three types on the same bone, each leaving its peculiar marks on the concentric layers of the diaphysis; so that the evolution of the malady and the pathological history of the bone may be thence reconstituted. The microscope also demonstrates that these three varieties, apparently distinct one from the other, are in reality different forms of the same morbid processes.

In effect, "if close attention be paid to structural details, it will be seen that gelatiniform atrophy, decalcification, and medullization consist—the first in a melting of the bone elements, for which is substituted a fibrillary net-work; the second in the absorption of the lime salts, and the third in the predominance of the soft over the

hard parts; while the osteophytes, which mark these different periods constitute a characteristic sign of the disease."

In these osteophytes the normal bone is replaced "by large spaces, disposed perpendicularly as regards the axis of the diaphysis, and by a net-work of connective tissue of vessels and a few medullocelles (sic)"; they are limited by osiform trabecules, surrounded by corpuscles resembling those of connective tissue, of irregular shape, having fibrillary prolongations, anastomosing about the angles. They form a net-work becoming more dense as the malady progresses, attaining the maximum in spongoid tissue.

"The fundamental anatomical element of these products of new formation is then the same at the different periods of evolution of the morbid processes. What causes the different varieties observed, is the quantity of the elements present, the width of the spaces separating the trabeculæ, etc."

M. Parrot asserts then, that he has established the identity of the three types of osseous alterations he has described.

Or, since the third type is rachitis, as ordinarily observed, it may be concluded that the presence of hard osteophytes and gelatiniform atrophy constitute rickets in newly-born children, and, on the other hand, as corollary, that rachitis is but the sign of hereditary syphilis, as it affects the bones towards the second year of existence.

M. Parrot has never met the first two types of bone alteration without concomitant syphilitic lesion. At the same time that hard osteophytes and gelatiniform atrophy are found, "some incontestable mark of hereditary syphilis will be revealed by careful examination, either in the viscera or on the skin." In children or adults, presenting rachitic deformations, the clinical demonstration is more difficult. But even in many of these cases evidences of actual or long-cured syphilis may often be found.

The doctrine of M. Parrot, as regards its most essential points, may then be summed up as follows: hard osteophytes, gelatiniform atrophy, and spongoid tissues are different varieties of the same disease. Or, since the two first are evidently of syphilitic origin, then the last also must derive from the same source, and we arrive at the general conclusion, that rickets is engendered by hereditary syphilis.

This doctrine has naturally provoked considerable discussion, for rachitis has been frequently observed where observation during a long course of years has never shown any trace of syphilis in the family.

And again, M. Parrot, at the Hospice des Enfants Assistés, is fixed in a situation where hereditary syphilis is very common. And besides being syphilitic, the children are exposed to all the causes which usually provoke rickets. That they are born of syphilitic parents is incontestable; but they are also poorly nourished, badly clothed; they have suffered from cold in low, damp localities; in fact, besides suffering from hereditary syphilis, they have been exposed to all the causes of organic degeneration, capable, according to all authors on the subject, of producing rachitis, without the presence of any morbid diathesis.

M. Cornil draws our attention in this respect, to an important fact. "Why," says he, "is rachitis rare in large cities where syphilis is frequent, but where the inhabitants are well clothed and fed, while it is frequent in certain country districts where the people live in misery?"

Is syphilis the unique cause of rickets, as is the bacteride of malignant charbon? In the very favorable centre of observation where M. Parrot is placed, out of 100 rachitic patients there is always 10 who present no appreciable sign of syphilis. And nevertheless, M. Parrot admits as signs of syphilis several accidents, which, according to other authors, are of very doubtful value.

The value of the lingual lesions and of certain cicatrices in the gluteal regions have been much contested in this respect.

And this is not all. M. Magitot, in an able communication to the Medical Congress at London, denies in toto the syphilitic origin of the dental alterations, attributed by M. Parrot to hereditary syphilis.

He reproaches M. Parrot with relying on the atrophy of the teeth to establish the diagnosis of syphilis, before proving, by rigorous clinical observation, the syphilitic nature of these alterations.

And then, how many individuals affected with hereditary syphilis, present no traces of dental atrophy. M. Magitot has found that the natives in Algeria, among whom syphilis has been endemic and hereditary for a long period, very rarely present any erosions of the teeth.

Have we not, on the other hand, observed individuals presenting marked alterations of the teeth, contract hard chancre? And yet it is generally admitted that hereditary syphilis preserves surely from the acquired disease.

Again, syphilis is a disease observed only in the human subject: and yet this same symmetrical erosion of the teeth has been observed by M. Magitot in cattle.

Finally, this author has observed forty cases of dental erosion where minute research has shown, in the great majority, complete absence of syphilitic antecedents.

But we will return to the figures furnished by M. Parrot.

In 100 cases of rickets, he found in 90 cases traces of hereditary syphilis, but if the bone lesions, alterations of teeth, and integumental cicatrices, admitted by him as signs of the disease, be eliminated, how many cases would present the other classic signs of the congenital diathesis?

However, the arguments brought forward by M. Parrot in the support of his opinion, are exceedingly plausible.

He brings forward the fact that the two maladies became generalized at about the same epoch, and that they are exclusively developed in the human subject, for the researches of M. Tripiér have demonstrated the falsity of the ancient opinion that rickets exists in animals.

And again, what a multitude of causes have been brought forward to explain the development of an affection of so characteristic an evolution and so constant a course. It is difficult to admit that the many opposing causes invoked can develop rachitism.

We would then be tempted to consider rickets as simply an accident of hereditary syphilis.

Unfortunately, even if the pathological anatomy seems to point in this direction, notwithstanding the adverse opinion of Kassowitz, clinical facts do not confirm the theory, and the magnificent and laboriously executed researches of M. Parrot are yet far from inspiring entire conviction in the value of his opinions.

COMMUNICATIONS.

REPORT OF AN OBSCURE AND FATAL DISEASE.

BY JOSEPH GIBB, M. D.

Read before the Northern Medical Association of Philadelphia.

I desire to bring the following case to the notice of the society, hoping that thereby there may be some light thrown upon what to me was an extremely interesting and puzzling case.

Richard C., æt. 26, colored, a strong, hearty man, has always enjoyed good health, never having been seriously ill, a moderate drinker, and by occupation a coachman, was taken sick March 3, 1883, as near as could be judged by a rather disconnected history, with pains in head, chest, and

limbs, together with chilly sensations and sweating. He was much exposed to the weather, as would naturally follow from his occupation. He continued with these symptoms for one week, and though feeling quite ill, did not give up his occupation, until the evening of the 9th, when he was obliged to do so by an exacerbation of the above symptoms, accompanied with dyspnœa. At this time there was a slight cough and trifling expectoration. When first seen the evening of the 10th, the most noticeable objective symptoms were great dyspnœa and heat of skin. The subjective symptoms were pains in head and limbs. In addition, it was noted: pulse was 130, rapid and compressible; temperature, $104\frac{1}{2}$; respiration, 48; tongue harsh and dry. Moves about the bed with great difficulty, each turn giving rise to expressions of pain. His mind was clear, though he manifested a dislike to being disturbed, and when allowed to rest for a moment relapsed into a sort of stupor, from which he could be easily aroused, and answered questions plainly and intelligently.

From the above symptoms, attention was naturally directed towards the chest as the seat of trouble, and a careful examination was accordingly made.

Inspection.—Movements rapid.

Percussion.—Slightly impaired resonance over base of right lung, extending to finger's breadth below nipple anteriorly, and nearly to angle of scapula posteriorly. This impairment was so slight that I could not convince myself that it existed except by comparison with the other side where percussion resonance was normal.

Auscultation.—Sibilant rales over both sides of chest, anteriorly and posteriorly. The respiratory murmur was over the base of right lung; the seat of impaired resonance was weak and distant.

These conflicting and negative physical signs led me to abandon the lungs as the seat of the affection, and turn my attention to other parts. The belly was not tympanitic, nor was there pain or gurgling in the right iliac fossa. Upon questioning, it was ascertained that his bowels had not been moved for one week. The symptoms were certainly typhoid in their nature, but upon examination there was not the slightest evidence of the specific disease.

There was some slight amelioration of the symptoms the next morning (11th), the temperature dropped to 103° , and there was not quite so much stupor, but towards evening he began to develop twitching of muscles around the mouth. The bowels had been freely opened by small doses of calomel frequently repeated; and thinking there

might be some malarial trouble 10 grains cinchona was given every two hours.

The next day (the 12th) the same symptoms continued, and in addition sub-sultus tendinum, jactation, and other nervous symptoms began to be developed. Urine was suppressed, or rather, retained. These last symptoms increased through the day, and in the evening, when seen in consultation with another gentleman, he was semi-comatose. Urine withdrawn with catheter was dark colored; upon examination contained no albumen. Pulse 144, fluttering; and the most remarkable of all the symptoms, the temperature, was 107° ; the respiration 45; abdomen tympanitic; no iliac tenderness; no eruption.

Again the lungs were carefully examined with a negative result. He rallied slightly on the 13th, being a little easier to arouse from the stupor, still the sub-sultus and nervous symptoms continued with a pulse of 130, weak, temperature $105\frac{1}{2}^{\circ}$, respiration 60, in the morning; pulse 120, more regular, temperature $103\frac{1}{4}^{\circ}$, respiration 54 in the evening. Was called early the morning of the 14th, and found him in the following condition: Oscillation of the eyes, twitching of different groups of muscles not regularly or symmetrically, which at times resembled clonic spasms. Pulse impossible to take because of the spasms. Temperature $105\frac{1}{2}$. These were all merely the evidences of approaching dissolution, which took place at 9 a. m. of this day.

The *post mortem*, which was made thirty-six hours after death, was nearly as negative in its results as the endeavor to make a diagnosis during life.

Chest.—No fluid in pleural cavities. Bands of organized lymph, with adhesions on both sides of chest showing the existence of an old pleurisy. The lung tissue was normal in appearance and perfectly crepitant, excepting at the base of both lungs, posteriorly, where there was hypostatic congestion as evidenced by the dark, almost black, color. It was easily lacerable, and was not entirely devoid of air manifesting a slight degree of crepitation.

Throat.—Normal.

Liver and Spleen.—Normal.

Kidneys.—Normal in appearance. Capsule non-adherent. Several feet of the ilium, the cæcum and portion of colon were removed and carefully examined. External appearances normal. The gut was cut open with scissors just at the attachment of mesentery. The mucous surface of this portion of intestine was intensely congested. At parts, and particularly around the ileo-cæcal

valve, it was of a scarlet-red appearance. At other parts the vessels were engorged, but the color of membrane was more dusky. No elevation or ulceration of Peyer's patches were noticed though carefully looked for. Circumstances would not admit an examination of brain and spinal cord.

Such is the history of this singular case with the results obtained *post mortem*. It is to be regretted that a more detailed account could not have been obtained from the incipency of this case to the time when I first saw him, when he was almost moribund. Though his mind was tolerably clear and remained so to the end, still it was with great difficulty anything could be obtained from him; all his friends seemed to know, was that he was very sick before he came here, and passed a good deal of his time sitting in a stable over a gas-stove, to which they attributed all his trouble. Had an accurate and full account of the earlier days of his illness been obtained, a diagnosis might have been more simple, as it was, it was extremely complicated. The idea of lung trouble was abandoned after the examination of those organs. A low typhoid condition: could it be typhoid fever? was the mental inquiry, if so, where were the iliac tenderness—the diarrhoea, the typical temperature, etc.? All absent. Typhus? No history of the causes which usually act in producing this disease—overcrowding, bad food, etc.; positively no eruption, though it was sought for several times. Had this eruption been present, the difficulty would have been solved, for the other symptoms pointed markedly toward typhus fever. Observe a rapid, feeble, highly compressible pulse, an unusually high temperature, mounting still higher as the fatal end approached, a hot, stinging skin, and cerebral symptoms indicating a typhoid condition, with absolutely no abdominal symptoms, save towards the very end, when tympanites developed. Being fully cognizant of the extreme rarity of sporadic cases of typhus fever, still I could not divest myself of the idea that this was a case of that nature. While a resident at the Philadelphia Hospital in the winter of 1880 and 1881, I saw a number of cases of this disease, though never without the characteristic eruption. In other respects, the symptoms of this patient were singularly like some of those treated in the hospital.

I should like to have the opinion of the members of the society in reference to this case, as it would in a measure mollify the chagrin felt at being unable to thoroughly diagnose it, and at the same time lead me into different channels of

thought, and thereby save me the mortification, should a similar case arise in the future.

TETANUS OR WORMS?

BY PAUL KEMPF, M. D.,
Of Ferdinand, Indiana.

On the 25th day of October, 1882, a butcher called at my office with his son, John Weber. The latter is nine years old, heretofore has enjoyed good health, and never had any convulsions in his babyhood. Three of his uncles died when young of cerebral meningitis.

Three weeks before he came to see me he was vaccinated with humanized virus. The vaccination proved successful, and two well-formed scabs were on his arm, but there was no undue amount of inflammation present.

The most striking symptoms on the above-named date were, a contorted face, difficulty in opening the mouth, vague pains everywhere, a stiff back, and a peculiar walk. Nothing further save negative points could be elicited by questioning the father. The temperature was normal, the skin moist and cool, and the bowels had responded by three watery actions to a dose of castor oil given the day before. Two six-grain doses of potassium bromide, and then two five-grain doses of chloral hydrate, were ordered.

On the night of this day I was hastily summoned to the patient's home. He was in severe convulsions. The jaws were firmly closed, the eyelids partly so, *risus sardonius* was well marked, slight opisthotonos was present, and he had bitten his tongue so that the blood flowed.

The thermometer registered 104° F.; the pulse was much accelerated. After a thorough examination, no lesions excepting those of vaccination, and several large herpetic sores around the anus, could be discovered. There was no tenderness or pain along the spinal column, and the mind was perfectly clear. Profuse sweating appeared at intervals. Occasionally, the boy would shriek out, and then the entire body was as stiff as a board. The jarring of a footstep on the floor, a draught of air, or the simple touch of my fingers, would bring on or intensify the general spasm. Tetanus was my diagnosis; whether idiopathic or traumatic, I was not prepared to say. The vaccination I suspected as a cause, however; but I took good care not to communicate my suspicions to the family. The chloral hydrate was increased to ten grains every hour till sleep was produced. On the next day eight grains of potassium bromide and a half ounce of the elixir of ammonia

valerianate were given at every third hour. The room was darkened, kept agreeably warm, and silence about the house was enjoined.

It soon became apparent that the chloral hydrate held the convulsions in check, and accordingly this medicine was continued, the dose being increased or given more frequently according to the severity of the attacks.

These attacks of spasm, especially after the first three days of the disease, occurred at night to a much greater extent than during the day. In fact, after this period of time, he had not once in daytime opisthotonos, but the "devilish smile" and rigidity of the legs were constant. I feared that malaria, the greatest factor in diseases in this part of the country, might have some influence in this case; so I gave twenty-five grains of quinia sulphate during two afternoons. No visible effect for good was created.

One night all the symptoms were aggravated. The *risus sardonius* was extreme; all the facial muscles were horribly contorted, and the patient foamed at the mouth, while his body formed a complete arch. No medicines could be given *per os*. The hypodermic injection of one-fourth of a grain of morphia sulphate quieted the patient. A stick of hard wood was then put between the teeth, to prevent further laceration of the tongue. My prognosis was necessarily gloomy. After the patient had lived through a week's illness, it became brighter, as nourishment, milk, eggs, beef tea, and small quantities of whiskey, were given at short intervals. I determined to stick to the original plan of treatment, and so the chloral hydrate at night, and the potassium bromide mixture during the day, were kept up.

On the eighth day of his illness the patient passed a large worm of the "*ascarides lumbricoides*" kind. I asked myself, could worms have anything to do in this case? The patient had extreme pains in the abdominal region, with contraction of the muscles there—but these things occur in nearly all cases of tetanus. Four grains of santonin in a drachm of fluid extract of senna and spigelia were administered at night. The next morning two more worms passed with the stool. On alternate nights the same vermifuge was given, and in all, thirteen large worms came away.

Sweating was very profuse at times, and a large crop of miliaria rubra appeared. Extreme itching was complained of. Simple vaseline relieved this greatly. Thus the disease progressed, gradually, becoming less in intensity, though there were occasions of exacerbation, till the seventh day of November.

On the night of this day the patient had the last severe convulsion. Sleep was however often interrupted for the next week by dreams, and to prevent these the chloral hydrate was continued, though in gradually diminished doses. The potassium bromide was now given twice daily. At the end of three weeks I pronounced the patient out of danger. The peculiar expression of the face then passed away, also the skin eruption and the swelling of the eyelids. The appetite became voracious: it had in truth never failed seriously throughout the illness. It may be mentioned here that the submaxillary glands had been enlarged and painful. No particular treatment was used for these, and they resumed their normal condition.

The power to walk returned but slowly; however, on the sixth day of December the boy was entirely well.

Was this a case of tetanus, or of reflex convulsions from intestinal worms? Looking over the standard works on these subjects, and considering all things, I thought it a case of tetanus, and treated it as such.

The course of the disease, the peculiar convulsions, the great sensibility of the nervous periphery, the enormous doses of toxic medicines taken, all point towards tetanus. On the side of reflex convulsions from worms, are the facts that the patient recovered, and that worms were present. May not a case of tetanus terminate favorably? May not the presence of worms be a coincidence? Or may not the combined irritation of intestinal worms and that of the vaccination sore have produced tetanus? At any rate it is an open question, and an unbiased mind will not jump suddenly at the conclusion that it was a case of reflex convulsions "produced by worms."

Professor of Anatomy.

Necrosis of the Phalanges of the Great Toe from Frost Bite.

GENTLEMEN: This is a case of frost bite. Before I tell you the different symptoms assumed in a case of this kind, we will try to get the information from the patient himself. The man says he wore a pair of coarse boots after his feet were frozen, a few nails stuck up in the soles of the boots and hurt his feet. Sometimes these pegs

are only wooden ones, at other times they are metallic. Some of these pegs projected through the soles of the boot and produced sores. Now the question comes up, Were those nails in the soles of this man's coarse boots the cause of this trouble, or is it due to the fact that his feet were frozen? It is very desirable to know. The irritation of those pegs might cause ulceration of the soft parts, but they would scarcely ever produce necrosis of the bone, deeply seated under them. In order to understand the pathology, it is necessary to trace it from the first stage. He says he experienced a peculiar tingling in the parts after they were exposed to excessive cold. That is the first symptom of frost bite. Then came numbness and whiteness of the parts, followed by redness, swelling, itching, and prickling. Perhaps every one of you has experienced some of the symptoms during very cold weather. The border of your ear, tip of your nose, points of your fingers, may have been slightly frost bitten, and you undoubtedly noticed the train of symptoms this patient has just described. Excessive heat has a similar effect in producing the first visible symptom of frost bite, viz, redness. Hold your hand by a fire, or expose it to the rays of the sun on a hot day, and it becomes red; increase the heat, and you increase the redness by dilating and irritating the capillaries; increase the cold, you diminish the redness by contracting the blood-vessels. Endeavor to restore the part by gentle rubbing and gradual elevation of temperature, and you may be entirely successful. If the frost bite has been severe, the part will be of a purplish color, almost the color of this man's nose. You have then a certain amount of stasis of the blood. We may have a still greater degree, and then you will have mortification take place. The first degree is where you have a certain amount of redness of the part; second, where you have a vesicle forming; third, where there is gangrene of the part.

You have three degrees of heat also; first, the erythematous blush where the part is exposed to a moderate amount of heat, especially in summer on a very bright day; second, where you have a more severe heat, and you will have a blister; and third, where there is still more severe heat, and you have sloughing of the part and gangrene. Cold is liable to produce any of these results. It is not the high dry cold that is liable to produce these results. This fact was proven during Napoleon's expedition to Moscow; retreating through Russia it was observed that during the extreme cold weather, when the atmosphere was dry and the thermometer away below zero, the soldiers did not suffer much; but when the thermometer was above zero, sleet falling and this accompanied by wind, then the men suffered most from the effects of cold. It is the cold with moisture, and not the dry cold, that produces the quickest and most marked effects.

Now before taking up the treatment, we will consider another variety; that variety where a person suffers from cold for a while and afterwards is overcome by it, gets drowsy, the circulation becomes sluggish, he is affected with stupor, falls asleep, perhaps never to wake again—general paralysis not only of a part but of the whole frame, a general impression upon the whole sys-

tem. When people have died from these causes, it was found that the fluids were all frozen throughout the body; it shows that the whole body was penetrated by this atmosphere.

The parts become very brittle. In histories of some of the wars we read that a great number of wounded were placed in ambulances and suffered severely; a general impression was made upon the soldiers by the cold, and quite a number had their limbs entirely broken off. It is very easy for a person with a frozen ear to chip off parts of it, which shows that the parts become very brittle.

What are we to do for such cases? Great care should be exercised not to bring on the reaction too suddenly in bringing back vitality to the paralyzed nerves and blood-vessels. Suppose a finger or a nose is frostitened, revive the vitality all at once, and the re-action would be too severe, and as a result we would have a failure in our efforts. If we put the part in warm water the rush of blood is intensified, and a heavy sensation because the blood cannot get through the arterioles; we have a determination of blood to the part—a stasis, following which we may have gangrene and sloughing. Do not make too sudden a change from one temperature to another. Use friction with the hand, also using snow or dipping the hand in cold water, keeping up the friction and in that way gradually elevating the temperature, coaxing the blood back by degrees. In this and other cases, where you have to resort to friction of the body, it should be kept in a cool room. In those cases that have been generally impressed by the effects of a very low temperature, you may assume that, whenever you find a pulse however feeble, and the least motion of the heart, the patient may be resuscitated. Do not place him in a warm room, that would be too sudden a change; stimulate and excite the vital powers by rubbing. After the respiration has become regular and the heart's beat increases, you may give stimulants—whisky, brandy and ammonia—in the meantime keep up the rubbing. To revert now to this patient. We see the great toes of both feet red, ulcerated, and œdematous, the œdema extending up both legs. Inserting a probe in those open sores, it comes in contact with dead bone, which we will proceed to remove. The general rule in these cases of necrosis is to wait until the sequestrum is detached from the healthy bone before operation. Sometimes new bone is thrown out and encircles the necrosed portions. Here is a case of two years' standing, and little progress towards recovery. The question is whether it is better to remove the source of irritation, or to allow it to remain in this state. The reason of the existence of this swelling is, that the diseased bone becomes a source of irritation which causes an excessive flow of blood to the part, the serum of the blood becomes effused into the surrounding tissue. We will now cut down to see what we can do for him; it is always the rule to take away all the diseased tissue and dead bone. I find as we get down that it is necessary to go above the metatarsal phalangeal articulation before healthy bone is reached, and with a chain-saw passed around the bone, we have no trouble in effecting its removal.

HOSPICE DE LA SALPETRIÈRE.

SERVICE OF M. BAILLARGER.

Translated for the MEDICAL AND SURGICAL REPORTER from "Annales Medico-Psychologiques" by A. A. Gleason, M. D., Elmhurst, N. Y.

Access of Melancholy Appearing at the Menstrual Epoch; Symptoms Intermittent—Cure by Sulphate of Quinine.

S—, aged forty years, seamstress, entered the Salpêtrière November 27, 1865. (Published May, 1882.)

We learn from the account furnished us by her daughter that the patient was very industrious, but of a sad disposition; her health generally good, appetite excellent, menstruation regular. They say that there have been no insane members in the family. Menstruation, which should have appeared November 20, has not come on. It may be added that for three weeks the patient has complained of flashes of heat in the head. Until then, however, no sign of intellectual derangement.

Delirium broke out November 23, in the evening. The patient maintained that she was bewitched. She threw various pieces of furniture out of the window. Complete insomnia, stupor, melancholic delirious conceptions, distress, anxiety.

At her entrance into the hospital, the same symptoms. Refusal of food. From time to time the patient pronounces a few words in a low voice; "They want to cut her in pieces; they are going to put her in the stove, plunge her into a kettle of boiling oil," etc.

November 28. The menses appear and last three or four days.

The state of the patient is not modified; the face remains sad; delirious conceptions persist, Refusal of food irregular.

December 12. A marked intermittence of the symptoms is observed.

The patient has a good and bad day very decidedly. During one day she converses reasonably; speaks no more of her delirious conceptions; her face is much less sad. The next day there is a reappearance of all the melancholic symptoms.

After having noted this intermittence of symptoms for a week, I administer the sulphate of quinine, and the attack does not occur next day. The medicine was continued for five or six days, and the attacks have disappeared (40 then 75 centigrammes of sulphate of quinine were given).

From this time the state of the patient has rapidly ameliorated; the appetite is excellent.

Very soon S— became completely conscious of her condition and recognized the absurdity of these delirious conceptions; she left Dec. 30.

The attack, as you can see, lasted scarcely a month.

If the causes are sought which caused this attack of melancholia, none can be found except the delay of five or six days in the appearance of the menses and the flashes of heat which had lasted three weeks; which appear very insufficient. The patient as we have seen enjoyed good health before this, and according to all accounts had experienced no grief which could ex-

plain the appearance of the delirium; but she was of a sad disposition.

Remark also that the appearance of the menses resulted in no modification of the melancholic state, which subsided very rapidly under the influence of the sulphate of quinine.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Conversational meeting April 26, 1833.

James Tyson, M. D., President, in the chair.

Dr. Charles K. Mills delivered the lecture of the evening on the

Medical Examination of the Brain.

The lecture was amply illustrated by diagrams and specimens prepared by Dr. Mills, and also by a series of preparations from the *Mütter Museum* of the College of Physicians of Philadelphia.

Dr. Mills passed by with brief allusions examination of the scalp, skull, and membranes of the brain, the cerebral space and vessels, and the best methods of determining volume, specific gravity, and cranial capacity. His chief object in the lecture was to discuss and demonstrate the proper procedures to be pursued in methodically examining the surface and interior of the brain, after the removal of its envelopes, for the purpose of discovering and accurately localizing lesions.

In order to make an autopsy of the brain proper in a rapid, methodical, and scientific manner, he considered several requirements necessary:

1. The superficial topography of the brain should be understood. The examiner should be able to pick out without hesitation the chief tissues and convolutions. He should also, of course, be perfectly familiar with the numerous superficial subdivisions of the base of the cerebrum.

2. The variations in the size, direction, or arrangement of cerebral fissures and convolutions most likely to occur should be known to him. Age, race, individual type, education, and other causes, act to produce variations and anomalies. The student thoroughly familiar with the diagrams and demonstrations of Ecker might find himself at sea in his first examinations if this fact is not remembered.

3. A knowledge of the internal structure of the brain should be possessed by the operator. He should understand not only its ventricles and horns, its commissures and peduncles, its foramina and aqueducts, but also its medullated structure, as exhibited by sections of the cerebral and cerebellar hemispheres made in various directions. Methodical cerebrotomy, practiced in the vertico-transverse, vertico-longitudinal, horizontal, and even in other directions, will give certain more or less fixed appearances which should be familiar.

The surface of the brain should be thoroughly examined for morphological peculiarities, such as deficiency or excess of fissures and gyri, confluence of fissures, simplicity or complexity of folds and furrows; and also, of course, for pathological changes, for atrophy, softening, hæmorrhages,

changes of color, etc. Dr. Mills described the fissures and convolutions as given by Ecker, and also called attention to some of the most common and striking variations from the usual type of the adult human brain, dwelling particularly on the fissures most likely to be confused—the pre-central, central, and retro-central, etc. The views and observations of Moriz Benedikt on the brains of criminals were referred to and criticised.

The examination of the fissures, convolutions, cranial nerves, and various regions of the surface of the cerebrum and cerebellum having been completed, the interior of the brain should next claim attention. The examination should be made in such a way as to cause as little disturbance as possible of the relations of parts by the incisions, and to allow, if desired, that the brain be brought together again after the autopsy and preserved as a whole. This could be done so as to submit every cavity, canal, part and structure to comparatively minute exploration. Some cerebrotomists, as Bitot, without stopping to investigate particularly into the various cavities and subdivisions, at once proceed to divide the brain into blocks by large incisions made at carefully-selected points.

The advantages of each of the three forms of sections—vertical transverse, vertical antero-posterior, and horizontal—were pointed out. The vertical transverse sections are the most generally useful. What are known as the middle transverse, mesolobar, or cortico-central zones are most important to understand. These comprise all the cerebral mass situated between the anterior and posterior extremities of the corpus callosum. Bitot describes and figures seven of these zones.

Sections and diagrams were exhibited by Dr. Mills, and the places and methods of making these sections were explained. The particular convolutions, and the regions of the ganglia, centrum ovale, capsules, etc., traversed by these sections were shown. The ganglio-insular region was particularly described. This region includes a large portion of the island of Reil, of the optic and striate ganglia, of the external and internal capsules, and of the external wall. The importance of having at command a fixed nomenclature for the various planes and regions was dwelt upon. Following the method of Bitot, the surfaces exposed by the sections were divided into a superior, inferior and middle division, and these were studied. A diagram representing the relations of the middle portion of the brain to cranium was shown and explained.

Dr. Mills said that he preferred to open the brain so as to expose its ventricles, horns, and parts, and examine each as nearly as possible in its integrity. By his methods such structures as the corpus callosum, septum lucidum, tænia semicircularis, velum interpositum, choroid plexus, fornix, foramen of Monro, pineal gland and its peduncles, etc., could be each in turn investigated for lesions.

After the cavities and horns had been exposed by proper incisions, methodical cerebrotomy, as advised by Charcot and Pitre, or Bitot, could be practiced, the cuts being made from within outwards, but not quite through the brain, so that the whole mass could be drawn together again after the cut surface had been examined.

Dr. Mills described three of the best methods of opening the brain:

(1) At the base, by taking as guides certain fissures and other anatomical landmarks.

(2) From the upper surface, by incisions through each side of the corpus callosum, or along the lower borders of the calloso-marginal fissures.

(3) By dividing the brain into two symmetrical halves by a careful median section. This should only be done after the parts in the median line had been previously explored.

Dr. Shakespeare said that he would like the lecturer to state why he prefers to open the brain from the base rather than from above. Dr. Shakespeare thought that by opening from above, the floor of the lateral ventricles would be better exposed, which contain the large ganglia of the brain, and a better topographical view would be obtained. The most usual cause for which the brain is examined is apoplexy. In these examinations it is necessary that very thin sections shall be made, so that all parts can be carefully examined. Dr. Mills has already pointed out the desirability of making these sections in such a manner that none shall be detached, so that when the examination is over all can be readily replaced, still leaving the brain practically in one piece. I believe that these two objects can better be obtained by making the examination from above, as taught by Prof. Orth (*Compendium der Pathologisch Anatomischen Diagnostik*) than by making it from below. The only part capable of holding the sections together is the cortex with its adherent vessels. Prof. Orth advises making a longitudinal section towards the cortex on a level with the corpus cal-

losum. This section is made deep enough to cut the cortical convolutions half through. This leaves enough tissue to keep the part attached. The anterior horn, the ventricles and posterior horn, are laid open by a second incision. Transverse cuts as thin as desired are then made in the side pieces. These cuts go half way through the cortex. The large ganglia are then sliced transversely, beginning at the front and going backwards. These are also made to go half way through the cortical substances of the base, and so on. The examination being finished, the parts can all be folded together like the leaves of a book, not a single piece having been detached. The only way I can see of making thin sections of every part of the brain by the other method is to divide it into two lateral halves and then making your sections towards the cortex; for if the sections be made directly across the brain the parts in front of the corpus callosum and behind the peduncles will be entirely detached.

Another objection is that seven sections are too few, and if it is desired to have more it will be a difficult task to hold the already cut sections in one hand and split them with the knife held in the other.

Dr. Bartholow preferred to open the brain from above, for similar reasons to those assigned by Dr. Shakespeare.

Dr. Eskridge expressed a preference for the older method.

Dr. Mills then closed the debate by reiterating and amplifying the arguments contained in his paper.

C. B. NANCREDÉ, *Recorder*.

EDITORIAL DEPARTMENT.

PERISCOPE.

Transfusion.

Dr. J. F. Le Page contributes an article on this subject to the *Brit. Med. Jour.*, April 21, 1883, from which we select the salient points, as follows:

"It is utterly futile to attempt to administer stimulants, when the functions of the stomach are altogether suspended or when it rejects everything; and to inject nutrient enemata, when the absorbent system is completely paralyzed and has lost its faculty of assimilation. We notice gasping, which is an indication that the respiratory centre in the medulla oblongata is not duly stimulated; the natural stimulant of the respiratory centre is carbonic acid.

"No inspiration, as an involuntary act, could, in health, take place, were it not for the presence of carbonic acid in the venous blood traversing the medulla. How, then, does it come that this centre fails after hemorrhage? In this way: The respiratory centre is the transmitter, at regular intervals, of nerve force to the respiratory mus-

cles; but it is not the mechanism which transforms matter so as to develop that force. Whilst carbonic acid is essential to the inspiratory act, oxygen is equally essential in the generation of that force which the centre transmits. Well, there is a deficiency of oxygen because there is a deficiency of blood in the brain; and what little is there, is in a state approaching stasis. Propel more blood through the cerebral vessels, and what happens? Oxidation goes on; force is developed, which the inspiratory centre, stimulated by the carbonic acid in the blood, rhythmically discharges, and respiration is re-established.

"This leads me to the indications to which these considerations point. Oxygen must be sent to the brain, carbonic acid to the respiratory centre in the medulla, and fluid to the heart. And how can we accomplish this? I have adopted this plan in patients who were not actually *in articulo mortis*; and, so far, with complete success. First, place the head low and raise the pelvis, so that blood may gravitate to the medulla; then autotransfuse—that is to say, transfuse the patient's own blood from the extremities to the vital centres. This is done by firmly bandaging both legs and

arms, commencing at the feet and hands. At this stage, either may with very great advantage, as a most valuable means of stimulating nature's powers, be injected intermuscularly; and I venture to suggest that it would be both rational and expedient to inject a minute quantity of strychnine with the ether, for strychnine we know to be a most powerful and certain stimulant of the inspiratory centre. It now becomes our duty to supply the patient with such nutriment as is capable of sustaining life; and to this end, should the stomach still reject liquids, the assimilation of nutritive enemata will meet the case.

"Striking as is the success of this treatment, desperate cases do occur in which there is absolutely no hope excepting by placing directly into the circulation new fluid capable of arousing and sustaining life; and in those cases, as in the resuscitation of the drowned, there is ground for hope even after death has practically taken place.

"A question of no little importance is that of the form in which the aliment should be used. There are many cases on record in which *whole* blood has been used with complete success. The same thing may be said of defibrinated blood, and also of saline alcoholic solutions. The objection to the use of pure blood is its tendency to coagulate. Clotting may take place in the heart, in the vein, or in the instrument. How, then, can we avert its coagulation? By the very careful exclusion of air, by preventing cooling of the blood, and by the admixture of a small quantity of ammonia. In the first drawing of my transfusion apparatus, I had a device by which I could inject small quantities of ammonia into the blood as it passed through the instrument. As this involved a more complex mechanism than I desired, I was led to an experiment which, so far as I know, is original. Not only ammonia, but salines generally, retard fibrination; and it occurred to me that a very convenient process would be that of preparing the blood of the giver before it was drawn from his vein. I need not here explain the experiments I made at length; but the deduction was this, that by administering ten minutes before blood is drawn, as large a dose of a saline with ammonia as can well be borne, fibrination is very materially retarded. I infer that, with the precautions against cooling and the admission of air, this preparation of the blood will effectively remove all danger from clotting.

Defibrinated blood has its advocates; and their grounds of preference are, that all danger of coagulation is avoided, and that it is unnecessary to bring the giver of the blood into the room.

In favor of the saline alcoholic solutions and milk, may be urged the impossibility, which must often present itself, of obtaining blood at the time when alone it can be of any avail; and the fact that they are always available at short notice. Dr. Hodder records, in the *Practitioner* of 1873, the cases of two patients, moribund from cholera, in whom he injected pure milk, in one fourteen ounces, in the other twenty-eight ounces. Both recovered. And here there was not simply a draining of blood to contend with, but a most potent poisonous influence. A teaspoonful of common salt, half a teaspoonful of carbonate of soda, with two tablespoonfuls of alcohol in a pint of water; or even simple water, with a few drops of

ammonia in it, may be used. Half the mischief arises from the heart and arteries having nothing to contract upon; and hence we see how it is that these simple fluids answer the purpose. It is, of course, necessary to follow up transfusion by warm enemata of beef-tea, with brandy, and probably a little opium; to keep the legs and body warm, and, as soon as deglutition can be performed, to give brandy and hot water.

The operation itself is performed thus: Transfix transversely a fold of skin pinched up in the course of a vein at the bend of the elbow. Seize the vein and raise it with forceps, which are made for that purpose. Then open by a longitudinal incision. An assistant may now compress the vein with his thumb, whilst a vein is opened in the same way in the giver's arm. Then, having carefully charged the instrument with a warm saline solution, insert the cannulas into the veins; of course, pointing centrally in the patient's and distally in the giver's arm. Now, propel the blood slowly and smoothly, and watch the effect. Six or eight ounces will probably be ample. Then remove the cannulas, apply a compress, and bind with broad tape with figure of eight round the elbow.

I am convinced that the time is not far removed when, to permit a patient to die of hæmorrhage, will be considered little short of culpable homicide; when transfusion will take its proper place in medicine, in surgery, in obstetrics: when many valuable lives will be saved, which would inevitably be lost but for a weapon so potent, so effective, in defeating our common enemy, death.

How to Secure the Best Possible Physical Condition after Parturition.

Dr. R. Tauszky read a paper on this subject before the New York Academy of Medicine, which, while it contains nothing strikingly new, is worthy of reproduction in parts on account of its practical nature.

First of all, the accoucheur should be careful to cleanse his hands with soap and water, remove all foreign particles from beneath the nails, and then wash the hands in either a three per cent. solution of carbolic acid, or, what is probably more available, pure vinegar, and afterward oil the hands with carbolized oil of the same strength of carbolic acid mentioned. All instruments and articles used about the woman should be cleansed and disinfected by similar means. Just prior to confinement, or early in the first stage of labor, the bowels should be freely moved by an enema, repeated if necessary. The bladder should be emptied, and if catheterization is necessary, the urine should be drawn with a soft Nélaton catheter, which has been thoroughly cleansed in boiling water, and afterward disinfected. The vulva should be bathed with some antiseptic solution, such as a very weak solution of carbolic acid, perhaps with the addition of a small quantity of glycerine, or with a solution of thymol.

The author recommended careful dilatation of the cervix with the fingers. He also spoke of the advantage which might accrue from gently pushing up the anterior lip of the cervix above the symphysis. Tough membranes also may be ruptured with great advantage. He recommended the

use of chloroform, especially in primiparæ, not carrying the anæsthetic, however, to the production of full unconsciousness. The forceps in very many cases, if judiciously used, were advantageous rather than disadvantageous, and should be used rather than allow the head or shoulders to press unduly, for any considerable length of time, upon the perineum.

The cord should not be tied until the umbilical vessels cease to beat. Dr. Tauszky regarded this as a point of practical importance. He also recommended Crede's method of expression of the placenta.

Dr. Tauszky laid special stress upon the occurrence of hemorrhage after parturition, and remarked that a little hemorrhage after parturition is very dangerous, and should be arrested. He took the strong position that the accoucheur should be regarded as guilty of malpractice who would permit a slight quantity of blood to escape from the genital organs of a woman for days after parturition. He maintained that not a single drop of blood should appear after the completion of the third stage of labor; that the napkins when removed should be perfectly free from color; that should they be colored the physician should at once institute an examination with reference to the source from whence the blood came, and set about arresting it.

The bowels need not be moved until the third day after labor. It is not necessary, is often dangerous, is even fatal sometimes to use intra-uterine carbolized injections once or twice daily up to the second day, even after natural labor. He believed that such injections should be used only when the lochia are offensive, and febrile movement has developed. When the lochia are offensive and there is some fever present he invariably syringes the vagina several times a day with a disinfectant solution, but intra-uterine injections post-partum are necessary only in cases of internal violence, such as sometimes attends the manual separation of the placenta or the use of the forceps. When such injections are used, he preferred thymol or simple water to carbolized water, which could be introduced either through a soft catheter or the exceedingly convenient tube invented by Dr. Chamberlain. The injections might be repeated until the fetor of the lochia was either markedly diminished or entirely corrected.

Dr. Tauszky protested against the teachings of Dr. Goodell, of Philadelphia, with reference to the parturient woman being permitted to assume the upright position within three days after labor. He believed that the doctrine was a dangerous one, and unwarranted, and maintained that the recumbent posture should be kept, changing occasionally from side to side, for at least eight days after normal delivery, and especially until the uterus has returned to the pelvic cavity. Dr. Tauszky then referred to his experience on the frontier while in the army, and stated that it was not only among the civilized, but also among the savages, that women suffer from diseases peculiar to their sex, and stated that gynecological affections among the squaws were not at all uncommon. He attributed a large percentage of these conditions to early rising after parturition. He then detailed the history of a case which terminated

fatally, and, as he believed, chiefly because of the early getting up of the patient.

For pelvic peritonitis, in case it developed, he regarded cold applications as the best that could be employed, but more especially in the early inflammatory stages.

Detection of Sugar in the Urine by Means of Test Papers.

In the *Lancet*, May 19, 1883, Dr. George Oliver thus writes:

Carmines of indigo is the sulph-indigotate of sodium, an intensely blue and soluble salt (solubility 1 in 120 parts water). Sulphuric acid when heated with indigo produces the soluble sulph-indigotic acid, which, after combination with a base (such as sodium, calcium, magnesium, etc.) provides us with insoluble indigo as a reagent in a perfectly dissolved state. When carbonate of soda is mixed with a solution of the carmine the latter is precipitated in a fine state of division; but when shaken this mixture may pass for a solution much like that of Fehling in color and general appearance. A perfect solution of a greenish-blue tint is, however, obtained after heating the liquid. As such it may be employed as a reliable, sensitive, stable, and non-caustic test for sugar in the urine; but on several accounts I give preference to the test papers prepared from its constituents. In their manufacture, it is true that great care is required to secure throughout the filtering paper a perfectly even distribution of the sulph-indigotate; but this result has now been accomplished to my satisfaction. The papers offer the following advantages over the liquid preparation: (a) Every paper is charged with the same definite quantity of the reagents; a uniformity is thus provided for the qualitative testing, which, moreover, becomes a standard of known value for the quantitative estimation. (b) The paper filters out a fine precipitate, so that the alkaline solution of the sulph-indigotate is perfectly transparent, and of a true blue; but, notwithstanding this fact, the color of any remnant of the reagent left on the paper is completely discharged by the sugar, so that in the quantitative estimation the colorlessness of the paper will be found the guide as to the termination of the completed reaction. (c) The portability, cleanliness, and stability of these handy tests must commend them to your favorable attention. The characteristic reaction which indicates the presence of glucose in the urine, arises shortly after the first simmer of the solution prepared from the papers, a drop or two of diabetic urine having been added before the heating. Then a beautiful violet tint suddenly spreads throughout the bright-blue solution; very quickly the violet deepens, and passes into purple; this in its turn melts into reddish-purple, which gives place to various tints of red, and these as quickly merge into orange-red and orange, and finally the solution becomes of a straw color, which remains without further change, though heated ever so long. At this point you will observe the paper of the same light-yellow color as the liquid.

The mode of testing is important. One of the papers should be dropped into an ordinary half-inch test tube, and as much water poured in as

will just cover the upper end; a column one inch in height and half an inch in diameter will thus be produced, and the solution obtained will always acquire the same concentration. Then not more than one drop of the suspected urine is let fall into the tube from a pipette, and heat is applied. After the first change of color it is advisable to move the tube away from the flame, and merely keep its contents hot, not boiling, in the higher part of the column of heated air above the flame; then all the colors will follow in the order I have given, without disturbance from ebullition, until straw-yellow is reached, providing the amount of glucose present is sufficient to develop all the prismatic colors; if not, another drop of urine should be added. The results of the working of this test by the side of Fehling were briefly as follows: (a) On always submitting one drop of urine to the indigo test, and the presence of sugar being shown, confirmation was invariably provided by Fehling used in the ordinary way. (b) On the other hand, whenever one drop of urine gave no reaction with the test, Fehling's solution did not give a precipitate. (c) On, however, taking more than one drop of urine a different kind of experience was opened up. Then with various urines a deep violent or purple tint would strike up on the addition of the second, third, fourth, fifth, sixth, or more drops, and Fehling employed in the usual way gave negative results.

Cannabis Indica; A Valuable Remedy in Menorrhagia.

In the *Brit. Med. Jour.*, May 26, 1883, Mr. J. Brown, of Bacup, observes:

"Indian hemp has been vaunted as an anodyne and hypnotic, having the good qualities of opium without its evils. Also in dysmenorrhœa and insomnia it has not proved of much benefit. The drug has almost invariably produced some marked physiological effect, even in small doses. Text-books give the dose as ten minims and upwards, but five minims is the largest dose that should be given at first. If bought from a good house, the drug is not inert or unreliable. A drug having such marked physiological action ought to have a specific use as a therapeutic agent. Indian hemp has such specific use in menorrhagia—there is no medicine which has given such good results; for this reason, it ought to take the first place as a remedy in menorrhagia, then bromide of potassium and other drugs. The *modus operandi* I cannot explain, unless it be that it diverts a larger proportion of blood to the brain, and lessens the muscular force of the heart. A few doses are sufficient; the following is the prescription:

"R.—Tincturæ cannabis indicæ,	℥xxx.
Pulveris tragac. co.,	3j.
Spiritus chlorof.,	3ij.
Aquam ad,	3ij.
One ounce every three hours.	

"Four years ago I was called to see Mrs. W., aged 40, multipara. She had suffered from menorrhagia for several months. Her medical attendant had tried the ordinary remedies without success. Indian hemp was given as above. Its action was speedy and certain. Only one bottle was taken. She was afterwards treated for anæmia, due to

loss of blood. Twelve months after this my patient sent for a bottle of the "green medicine." I learnt afterwards that she had sent this medicine to a lady friend, who had been unsuccessfully treated by another medical man for several months for the same complaint. It proved equally successful. The failures are so few, that I venture to call it a specific in menorrhagia. The drug deserves a trial. It may occasionally fail; this, however, is not to be wondered at in a complaint due to so many different causes, and associated with anæmia and other cases of plethora."

Robert Batho, M. D., M. R. C. P., Castletown, Isle of Man, writes in reference to the same subject: "Considerable experience of its employment in menorrhagia, more especially in India, has convinced me that it is, in that country at all events, one of the most reliable means at our disposal. I feel inclined to go further, and state that it is *par excellence* the remedy for that condition, which, unfortunately, is very frequent in India.

"I have ordered it, not once, but repeatedly, in such cases, and always with satisfactory results. The form used has been the tincture, and the dose ten to twenty minims, repeated once or twice in the twenty-four hours. It is so certain in its power of controlling menorrhagia, that it is a valuable aid to diagnosis in cases where it is uncertain whether an early abortion may or may not have occurred. Over the hemorrhage attending the latter condition, it appears to exercise but little force. I can recall one case in my practice in India, where my patient had lost profusely at each period for years, until the tincture was ordered; subsequently, by commencing its use, as a matter of routine, at the commencement of each flow, the amount was reduced to the ordinary limits, with corresponding benefit to the general health. Neither in this, nor in any other instance in which I prescribed the drug, were any disagreeable physiological effects observed.

"I could say a few words in its favor, as to its action in allaying irritative cough, but I prefer confining myself to a point on which experience has left me no room for doubt."

The Abortive Treatment of Infectious Diseases.

At the opening of the third session of the Second German Congress of Internal Medicine (*Medical Record*, June 2, 1883), Dr. Binz, of Bonn, presented a paper upon this subject.

Two causes were at work which tended to make infectious diseases less dreaded now than they were in former ages. These were an improved hygiene and an improved therapeutics. Hygiene alone will not suffice to prevent entirely the occurrence of epidemics, for the simple reason that it can never become perfect; and as long as a single focus exists favorable to the growth and development of the matter of contagion, there is danger of its spread to other localities. Hygiene and therapeutics must go hand in hand. But though we can never hope to prevent absolutely the occurrence of any infectious disease, the author believed that the time would come when we could strangle the disease at its inception and thus rob it of most of its terrors. We have already five remedies which we can send after certain excitors of disease to paralyze them and abort the

diseases to which they give rise. These remedies are quinine, mercury, iodine, arsenic, and salicylic acid. The antagonism of quinine to the malarial poison was dwelt upon; the explanation of its action being that it was a poison to the micro-organism found in this disease. This was not mere conjecture, but had been proven by direct experiment. Although at present there were no remedies to be regarded as specific antidotes to the microscopical organisms found in tuberculosis and diphtheria, Dr. Binz believed that they would some time surely be found. These diseases were now in the same condition as were rheumatism and malarial fevers before the discovery of the antidotal effects of salicylic acid and quinine. In concluding, the speaker predicted a glorious future for therapeutics.

Dr. Rossbach, of Jena, followed with a thoughtful article upon the same subject, agreeing with Dr. Binz in his hopes of vanquishing these enemies of mankind. He advocated the establishment of a special commission to study the action of the various drugs now in our possession, and of others yet to be discovered, to determine their proper dose and to ascertain their poisonous effects upon the lower as well as the higher organisms. In case of an epidemic occurring in any locality, this commission should recommend some particular remedy, whose action was supposed to be inimical to the disease in question. This remedy was then to be used by all physicians in their treatment of the disease, and a report could be made to the central body, upon the subsidence of the epidemic, of the results obtained by the various observers. In this way we might hope to make rapid advances in our search for specific therapeutical agents.

The discussion which followed was without special interest. The speakers agreed upon the desirability of the establishment of some such commission, which could formulate some general plan of investigation, and collate the results obtained by individual workers.

Malignant Pustule.

At a recent séance of the Académie des Sciences, M. Richet read an interesting communication on this subject.

In 1880, two cases were observed in his service at the Hotel Dieu; the first was a butcher, who presented a sore on the right cheek, accompanied by considerable induration of that side of the face and neck; the general symptoms were of a very grave character.

Serum taken from the sore itself, and some blood obtained from the index finger, were introduced under the dermis of several animals, and all thus treated perished, presenting all the symptoms of malignant charbon. The patient was energetically treated, subcutaneous injections of iodine solutions were made all about the sore, and the actual cautery applied.

The local troubles were somewhat ameliorated, but the general condition became graver, and the patient succumbed in 48 hours.

In the second case also the general symptoms were of great gravity, the temperature very near 104°, pulse 108, great thirst, with extreme prostration. All about the sore, down to the neck,

there was a hard, œdematous swelling; the lymphatic glands under the lower jaw were swollen and painful. Neither the blood taken from the finger nor the serum of the pustule contained germs or charbon bacteria, as in the first case. Nevertheless, the liquids about the sore communicated the charbon infection to animals inoculated with it.

The treatment in this was similar to that practiced in the other—injections in seven or eight points in a circle about the sore of from four to eight grams of tincture of iodine, diluted with twice the quantity of water. The patient recovered, showing that if the case be energetically treated before the infection becomes generalized, a complete and rapid cure is possible.

BOOK NOTICES.

The International Encyclopædia of Surgery. Edited by John Ashhurst, Jr., M. D. In six volumes. Vol. III. New York. Wm. Wood & Co. 8vo. pp. 760.

The thorough and practical manner in which the various branches of surgery are discussed in this volume cannot fail to gratify those who have subscribed to the work. The articles contributed to it are all quite up to the mark of their predecessors and are in themselves complete and original treatises.

The main topics treated of in this volume are the injuries and surgical diseases of muscles, the vascular system (blood-vessels and lymphatics) nerves and joints. Such subjects as aneurism, tetanus, hemorrhage, ligations, vascular and nervous tumors, neuralgia, and dislocations, come within the scope of the volume, and are presented in an entirely satisfactory manner.

We would also mention as specially commendable, the numerous illustrations, the care with which they are printed, and the good quality of the paper and presswork. Such mechanical aids to study are by no means to be depreciated.

Handbook of the Diagnosis and Treatment of Diseases of the Throat, Nose and Naso-pharynx.

By Carl Seiler, M. D. Second edition. Philadelphia. H. C. Lea's Son & Co. 8vo. pp. 288.

Dr. Seiler has taken advantage of an early call on him for a second edition of this useful manual, to revise it thoroughly and to make extensive additions to the text, especially in the portion which treats of the diseases of the nasal cavities. New wood-cuts have also been inserted, and likewise a sketch of a case record-sheet for keeping a complete record of cases.

As a convenient, well-arranged and carefully-prepared monograph, it is safe to say that this volume stands in the first rank.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance :—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE PRACTICAL VALUE OF THE BACILLUS
TUBERCULOSIS.

While the wordy warfare wages concerning the causative properties of this bacillus, it is well for us to gather together whatsoever we may of practical value in our every-day work, concerning it.

Dr. G. A. Heron, who recently delivered a lecture on the subject, (*British Medical Journal*, April 28, 1883,) has found the bacilli in the sputa of 116 patients, all of whom presented, sooner or later, what he considered unmistakable evidences of consumption. He has not yet seen a case, with absolutely no signs of lung mischief, in which he has detected the bacillus of tubercle in the sputum. He has found them in the sputum of a patient in whom there were no signs of lung disease, but where, after a time, consumption manifested itself, which condition was verified *post mortem*. From his own experience and the authorities he quotes, it would seem reasonably fair to assume that when the bacilli tuberculosis are found in the sputum, it is a pretty strong indication that the patient is either threatened with, or actually has consumption, and when, in connection with their presence, physical signs exist, the diagnosis can be made with considerable accuracy.

When very plentiful, the prognosis is unfavorable, and vice versa.

Wherefore it would seem that whenever we have any cause to suspect tubercular troubles, as in long-delayed convalescence after pneumonia or in otherwise unaccountable prostration, and the like, it behooves us to make a microscopical examination of the sputum for bacilli; if we find them, we can enjoin the usual precautions and advice for consumption, which, to say the least, will be harmless, even though the disease does not exist.

Whether these bacilli are really the cause, *per se*, of consumption, we do not yet know; but if they afford us, as it would seem that they do, a means of detecting the disease in its incipency, an acquaintance with them is a very valuable acquisition to our knowledge. The following is the process described by the author for detecting the bacilli:

"There is, so far as I know, no other

method but Ehrlich's now in use for staining the bacillus of tubercle. Various modifications of his process have been suggested; but, in all points of importance it remains as it was given to us by Ehrlich himself. The modifications, which are improvements of this process, aim at giving the staining mixture a uniform composition; and several different formulæ have been suggested for that purpose. The one now in use in this hospital, and I have myself used it for some months past, is Weigert's. Its composition is saturated alcoholic solution of fuchsin, or methylene violet or gentian violet, 11 parts; anilin water 100 parts.

"In warm weather good results are to be obtained when the staining process is carried out at summer temperature, and without the use of artificial heat. I should advise you, however, always to stain your specimens while they are exposed, in an incubator of some kind, to a temperature of 98° to 100° Fahr. Want of attention on my part to this important point caused me much inconvenience when the cold weather set in last autumn.

"The process I have just described to you occupies some time. It has, however, certain advantages. Not only does it ensure thoroughly good staining of the bacilli, but the specimens, while being stained, may be safely left for from half an hour to ten hours, or even longer, in the fuchsin and anilin mixture, just as the experimenter finds most convenient. There is, however, a more rapid way of staining. The same standing fluids are used. A little of the fuchsin dye is filtered into a watch glass, the specimen to be stained is placed in the fluid, and heat is applied. I have been accustomed to apply the heat by lighting a Bunsen burner, not at the top of the funnel, but at the burner itself. The heat, of course, passes up the Bunsen funnel, and so reaches the watch-glass, placed at a convenient height upon a tripod. I find that one minute's exposure to the action of the staining fluid, under these conditions, is sufficient to ensure excellent coloring of bacilli in sputum or in pus. The rest of the process is identical with that I have already described to you. Following this plan, it is easy to stain, and examine with the microscope, a specimen of sputum within ten minutes' time. Most of the specimens of the tubercle-bacillus in sputum and in pus which you see here to-day, have been prepared in this rapid way. In speaking of these staining fluids, I have called the red dye fuchsin. That is the name in use on the Continent for the coloring matter which in England we call magenta."

Since practice alone can enable one to recognize the bacillus when he sees it, and since no wordy description could convey a true likeness of it, we would advise those of our readers, not already familiar with it, to seize the first opportunity to visit some microscopist and familiarize himself with the appearance of the bacillus.

PROLONGED SUSPENDED ANIMATION.

Our journals have recently had occasion to re-

port an unusual number of cases of suspended animation and apparent revivification. One case reported in the *Med. Times and Gaz.*, May 26, 1883, is very striking. The patient had been drinking freely, and was on the verge of delirium tremens, when he was given a hypodermic injection of four minims of Squire's solution of morphia and atropine. He soon became drowsy, and could not be roused from the profound slumber in which he was. In two hours, his wife hearing a peculiar noise in his chest, "like a clock running down," put her hand over his heart, and found it beating very hard. It then suddenly stopped. She now placed her ear to his chest, but could hear no sound. She also noticed that "his face was very black."

Dr. Robert Brannigan, who reports the case, arrived at the house two hours later, and found the patient lying on his back, arms folded across the chest, covered up to the chin with bedclothes, and his head propped by three pillows. His face was livid, jaws clenched, pupils widely dilated and giving no response to light. He could not detect any sign of respiration or pulse, and in fact the man seemed quite dead. His body was warm and livid, but the hands and feet were cold and pale.

The use of the electro-magnetic battery for fifteen minutes produced absolutely no results (artificial respiration had been previously tried and failed).

Continuing the electric stimulus a few minutes longer, the lower jaw was drawn towards the sternum, and on one of the electrodes slipping over the brachial plexus, the arm was drawn up.

After one hour of continuous labor with the battery, the heart began to beat feebly, and in fifteen minutes more the pulse was 120, and the respiration one to the minute. When the electrical stimulus was stopped, the respiration ceased. To make a long story short, the respiration slowly increased in frequency, until after six hours from the time of commencing the electricity, the patient regained consciousness.

In the same journal, Dr. William Alexander reports a very similar case, only here the dose was much larger.

These cases teach us two practical lessons :

1st. That we should be very cautious in handling such a very potent drug as opium. Its great value in relieving pain is apt to tempt us to its injudicious employment.

2d. That we should persevere for a long time in our efforts at resuscitation when life has apparently fled, from a narcotic poison; since the inherent power to respond to electrical stimulation may be present, when, by maintaining an artificial vitality until the poison is eliminated, we may save our otherwise doomed patients.

And they suggest to us two queries :

1st. Is the usual antagonism existing between morphia and atropia, converted into an intensity of action of one of them when they are taken together ?

2d. Does alcoholism produce an unusual susceptibility to the toxic action of these drugs ?

LEUKAEMIA AND PSEUDO-LEUKAEMIA.

Professor Senator presented to the students in his clinic in Berlin, two very interesting cases. They were twins, æt. $1\frac{1}{2}$, born of healthy parents, nursed by their mother up to their 14th month, and later fed mainly on cow's milk. The children were perfectly well up to their 17th week, when they commenced to get sickly. In both a moderate degree of rachitis developed itself. Very remarkable was the extraordinary pallor of their skin in connection with their greatly hypertrophied spleens. On examination of the blood it was found, that in both the white globules were decidedly augmented; in the one child there were five, in the other two and a half times more white corpuscles than red. Whether in these cases there existed the disease of leukaemia or pseudo-leukaemia, does according to Senator by no means depend upon the relative increase in number of the white globules; as many cases are on record, where they are not increased at all, or only very little, and notwithstanding the case runs the same course as one of leukaemia. Besides, the relation of the number of globules to each other changes more and more with the progress of the case, as was noticed also in the twins; a few weeks

later the ratio was already in one that of 1:50; in the other that of 1:45.

Leukaemia, which is better recognized by this peculiar tendency of the white globules of continuously increasing their relative number, is according to Senator not any rarer in children than it is in adults. Hereditary causes here had no influence, the less, as the children were all perfectly healthy and the parents too. The rachitic process could not have exerted any special influence on the peculiar composition of the blood, as it was one of very mild degree only, and as, notwithstanding the latter disease is an exceedingly common one, these are the first instances on record, that genuine leukaemia had complicated rachitis. While Senator himself admits that he at present has no theory to offer as yet, to explain the pathogenesis of leukaemia, he believes that there are other factors at work, of which we do not possess any knowledge, and which can be elucidated only by carefully reporting all cases which have any bearing whatever on the question.

HEPATIC ABSCESS.

It would seem that abscess of the liver may be considered as somewhat more common than is ordinarily supposed, and that our attention should therefore, be more frequently directed in this channel, when we have to do with vague, ill-defined and marked symptoms of hepatic derangement.

An accurate diagnosis from physical signs is by no means an easy task, but happily we have in the exploring needle a crucial test, when we otherwise have good reason to apprehend purulent accumulation. Dr. Joseph Fayrer recently read a valuable paper on the subject of "Abscess of the Liver" before the Medical Society of London.

He traces a causative relation in many cases between dysentery and hepatic abscess, the absorption of pus or septic matter from the ulcerated bowel acting as the cause, and he advocates exploration to ascertain the presence of pus, early evacuation whenever it can be got at, and early and free opening; drainage, and antiseptic dressing whenever practicable.

In the discussion which followed the reading of the paper, Surgeon-General Hunter drew the following pen picture of the disease:

"The man has had malaria, or lived intemperately, or both. He gets out of condition, loses flesh, has 'hepatic' dyspepsia; then a localized swelling over the liver is noticed, and, if contracted, it will burst in one or other direction."

He also advises the exploratory puncture, and recommends free opening with antiseptic drainage.

THERAPEUTIC VALUE OF NITRO-GLYCERINE.

At a recent séance of the Société de Thérapeutique, this subject came under discussion. M. Huchard had experimented with a one per cent. alcoholic solution, in the dose of from one to six drops. After from four to six minutes there supervened cephalalgia, vertigo, a sensation of fullness in the head, ringing in the ears, and amblyopia. At the same time there was marked congestion of the face, acceleration of the cardiac movements, with diastole of the pulse, which became stronger and more rapid.

In a word, nitro-glycerine induces cardio-vascular excitation, with cerebral hyperemia and fall in peripheral tension. It may then be considered as analogous in its action to nitrite of amyl, and may be used in aortic disease and in cases where cerebral anemia is present, through troubles of circulation.

M. Huchard has employed it in a case of aortic insufficiency, where vertigo was complained of, accompanied by angina pectoris. In this case much benefit was experienced, as also in two other cases of angina pectoris; in another case it gave no decisive result. M. Huchard and other French observers do not seem to have obtained the beneficial results claimed for the drug by English physicians in affections of the respiratory organs.

M. Huchard uses the following solution:

R. Sol. nitro-glycerine (1%), 30 drops.
Aque destill., 300 grams.

M. Dose. A dessert-spoonful three times daily.

In the discussion which followed M. Huchard's

communication, the general opinion of the Society seemed to be against the medicament, as one of great and dangerous powers, whose therapeutic effects were not as yet sufficiently investigated.

CHLOROFORM NARCOSIS DURING SLEEP.

The question whether or not a sleeping person can be anesthetized without being first awakened, has, in view of the reported cases of the use of chloroform by villains for various nefarious purposes, assumed some practical importance.

The question has been recently discussed in the *New York Medical Record*, and quite a number of cases have been reported by the upholders of both sides of the question.

From an impartial review of the evidence adduced, the following conclusion would seem to be justified:

A sleeping person can be anesthetized without being awakened, if the agent holding the chloroform be first kept at a considerable distance from the individual and gradually brought nearer, so that the irritating influence of the chloroform on the respiratory passages may be avoided until its obtunding effect has been procured.

NOTES AND COMMENTS.

The Treatment of Granular Lids.

After relating some cases treated with *jequirity*, Dr. W. A. Brailey says, in the *British Medical Journal*, May 19, 1883:

The result of these and other cases shows that, in *jequirity*, we have a drug of decided value. Though it does not, in ordinary cases, immediately destroy all the granulations, it diminishes very considerably the pain and photophobia, and has a decided influence in clearing the cornea. Nor does it appear to affect this tissue injuriously, in which respect we must admit it to be decidedly superior to inoculation from cases of ophthalmia neonatorum. At first, I had considerable hesitation about introducing cases of inoculation with *jequirity* into the general eye ward; but I have not found that it makes any difference to the progress of other cases, whether operative or not. Though precautions against contagion have naturally been taken, we have not succeeded in inoculating into the sound eye the ophthalmia produced by this agent.

The seeds, which are extremely hard and tough, are first broken and freed from their shell. They are infused for two hours in cold water, in the proportion of 1 to 50; by this time they are so softened as to be easily pounded up, after which they are soaked in the same water for twenty-two hours more. The solution now requires only careful filtration to be ready for use. It is applied to the everted lids, or, when this is impossible, between the lids, thrice daily, till a severe conjunctivitis, of a purulent or diphtheritic type, is produced.

Congenital Sarcoma of Abdomen.

To the Glasgow Pathological Society (*British Medical Journal*, March 3, 1883).

Mr. H. E. Clark showed the specimen. The child from whom it was removed was, at the time of death, about a year old. The tumor had first been noticed immediately after birth, as a slight swelling in the neighborhood of the femoral ring, and resembled a hernia, but was irreducible. When the child was between two and three months old, a swelling appeared in the inguinal canal, and passed gradually down towards the testicle; it had, at the canal, a diameter of about half an inch, and for some time it did not involve the testicle; its appearance caused the recession of the tumor in the femoral region, which completely disappeared. The growth was not very rapid. About two months before the child died, the abdomen began to enlarge, tortuous veins appeared in the abdominal wall, and rapidly extended upwards to the umbilicus, ultimately reaching the chin. The child began to lose flesh, and to suffer from gripes and diarrhoea, and when twelve months old it died. The *post mortem* examination was made by Dr. Lindsay, of Lesmahagow, under whose care the child had been. He found the tumor occupying the greater portion of the abdominal cavity, and involving the whole of the spleen; it also passed down into the scrotum, and involved the testicle. It was free in the abdomen, but at the back was attached by means of numerous vessels to the mesentery, and above was adherent to the transverse colon, and below was firmly adherent to the bladder. All the organs, except the spleen and testicle, appeared to be healthy, but there were evidences of slight peritonitis. The whole tumor was composed of small round cells, with a very small amount of homogeneous matter, the cells entirely agreeing with those distinguishing the round-celled sarcoma.

Foreign Body in the Urethra.

"On examination, a foreign body could be felt lying along the under side of the penis, from its lower half towards the perinæum; and about the middle of the penis a sharp point was discovered. A small incision was made through the skin over it, and the point of a large black pin was then forced through, seized by a pair of forceps, and drawn out; it was between three and four inches in length. The head of the pin was then found intact in the urethra; the point of the pin was therefore depressed, and the head pushed up through the urethra and drawn out through its orifice. A catheter was passed, and left in the bladder for twenty-four hours, and the wound dressed with carbolic oil. Blood was passed in the urine several times afterwards. No urine escaped by the wound, and at the end of the week the man was sent out, cured."

Dr. Wm. Curtis reports this case in the *Brit. Med. Jour.*, May 19, 1883. The pin was introduced when the man was drunk. We may be called on suddenly to such a case, and it will be well to bear this case in mind.

Tinea Versicolor.

Tinea versicolor or *Liver Spots* is an exceedingly common affection, and one that causes much annoyance, since the patient frets at having this blemish on his skin. To cure it, Dr. George H. Rohé (*Med. Record*, June 2, 1883,) recommends a lotion of hyposulphite of sodium, half a drachm to the ounce of water. The patient is directed to take a bath once a day, using soap freely. After the bath the affected spots are to be mopped with the parasiticide lotion. In a week the discoloration has usually disappeared. The remedy should be continued a week or two longer to prevent relapse. Dr. Rohé says it is surprising to what an extent cases of tinea versicolor are treated for syphilis, hepatic derangement, or similar supposed affections of the internal organs. Patients are sometimes compelled to take mercury or potassium iodide for months, under the supposition that they suffered from syphilis, when the only trouble was that just described, which, when properly treated, yielded to local remedies alone in the brief space of two weeks.

Cerebral Atrophy Consecutive to Amputation.

At a recent séance of the Académie, M. Bourdon reported a case, confirming his anterior researches relative to the occurrence of cerebral atrophy long after amputation. He examined the

brain of a soldier who had undergone amputation of the left arm some forty years previously.

He found considerable atrophy of the entire right hemisphere, affecting principally the white substance of the organ. This atrophy was most marked at the superior part of the motor zone of the outer layers of the brain, and had gradually become extended toward the centre, producing paralysis of the lower limb, corresponding to the amputated arm. What would seem to be proven by this case and the six others reported by M. Bourbon is that the cerebral atrophy, at first due to the loss of functional activity in the amputated limb, becomes gradually extended to other parts of the brain.

Anti-quinine Treatment of Intermittent Fever.

At a recent meeting of the Medico-Chirurgical Society of Montreal (*Med. News*, June 2, 1883), Dr. Beardsley gave the results of fifty years' experience in treating intermittent fever without quinine. Briefly, it is as follows:

First, brisk alterative purgatives, aloes, blue-mass, and capsicum in equal parts, made into pill-form, or calomel in place of the blue-mass. An alterative purgative was to be taken at the outset, and repeated as the nature of the case demands. This was to be followed by an aromatic bitter, and perhaps an alkali with it, or in combination with boneset tea, drunk very freely, was an element in the cure not to be overlooked. He stated that this method had been very satisfactory in his and others' hands, and was often successful where quinine had utterly failed, and that, too, where it had been pushed; indeed, as far as twenty-grain doses three times a day, or even oftener.

The Cost of Vegetarian Diet.

The great temperance enthusiast, Dr. Norman Kerr, recently furnished a vegetarian dinner to one hundred persons. The repast consisted of three courses, accompanied by a plentiful supply of brown bread and a cup of excellent cocoa for each guest. A "hotch-potch" soup was first served. The ingredients in this were potatoes, turnips, carrots, leeks, celery, green peas, parsley, and butter. It was palatable, and it is claimed for it that it is nutritious. The next dish was a savory pie made up of haricot beans, flour, onions, and butter; and then followed the sweets, in the shape of a pleasant hot mess of rhubarb, rice, and sugar. The cost of the entire meal was less than \$6.25, being at the rate of six cents each person.

Morbillic Rash in Typhoid Fever.

We have already reported two cases in which a scarlatiniform eruption occurred in the course of typhoid fever, and now Dr. Walter C. Beevor reports another similar case to the *Brit. Med. Jour.*, May 19, 1883. The patient was nursing two typhoid cases, when she was taken with fever, headache, pain in back, and thirst. On the third day a rash exactly resembling measles appeared. On the fourth day typhoid fever was pronounced. These cases may be explained on the supposition of the co-existence of two zymotic poisons in the blood at the same time, since we do not know that these poisons possess any special antagonisms, the one for the other.

Syphilis and Rickets.

M. Cazin does not accept M. Parrot's view that rickets is an effect of congenital syphilis. He has collected a number of cases of each disease without the other.

Another fact confirmed him in this opinion, and that was, the treatment which, when consisting of mercury and iodide of potassium as forming the anti-syphilitic treatment, had not only no effect on rickets, but was positively injurious. If rickets were the result of a diathesis, it would be that of struma, and certainly not syphilis. M. Despres sided with M. Cazin, and said that whereas rickets can be cured by cod-liver oil and phosphate of lime when not too advanced, congenital syphilis is nearly always fatal, no matter what the treatment.

The Causation of Typhoid Fever.

The *Brit. Med. Jour.*, May 19, 1883, contains an address on "Typhoid Fever in Paris during the years 1875-1882," which concludes as follows:

"To sum up: these detailed conclusions support the considerations which I have laid before you; they impress on us the necessity of new researches, before assigning to typhoid fever a simple, regular, and constant etiology. In the meantime, we must not lose sight of the fact that typhoid fever is an essentially human disease, in the sense that it derives from the internal and external conditions of man the principal elements of its existence."

Loose Bodies in the Knee Joints.

These bodies, familiar to all surgeons, are believed by Dr. Oliver Pemberton (*Lancet*, May 19, 1883,) to be due to a chipping or breaking off of the joint surface, and that as time goes on the

loose body thus produced is found to present appearances according to its age and, as it were, to the extent of the wear and tear in movement it has undergone: at one time being cartilaginous or fibrous, or osseous or mixed, as the case may be, the ultimate shaping and structure of the body being doubtless greatly influenced by the predominance of the rheumatic habit.

He removes them by incision.

Suppositories in Chronic Cystitis.

Against the attacks of pain, which supervene in chronic cystitis, the use of anodyne suppositories frequently gives greater relief than any form of internal treatment. The following prescriptions of Mallez and Mayet will prove useful:

R. Morph. hydrochlorat.,	1 to 2 centigrams.
Stramonii pulv.,	2 centigrams.
Ol. Theobromæ,	q. s. M.

For one suppository.

R. Hydrat. chloral,	3 grammes.
Ol. theobrom.,	q. s. M.

For one suppository.

Combating Fever in Young Children.

It is often difficult, and in fact not without danger, to administer any efficient febrifuge to young children. In such cases the administration of sulphate of quinine by inunction offers many advantages.

The absorption of the salt is rendered possible by the extremely thin epidermis in very young children. The following unguent will be found efficient:

R. Quinæ bisulph.,	gr. xxx.
Camphoræ,	gr. xv.
Unguent. simpl.,	3 vj.
M.	

A small quantity may be rubbed in over the groin or in the axilla.

Premature Alopecia.

In the *Berlin Klin. Woch.*, Dr. Lassar advises washing the scalp every day for fifteen minutes with soft glycerine or tar soap, or soap containing iodide of sodium. Follow this with the warm douche, gradually cooled, and then use water containing two parts per thousand of corrosive sublimate. After drying the hair, rub in a one-half per cent. spirituous solution of naphthalin. This treatment must be persevered in for two months or more.

The Value of Re-vaccination.

Two women were vaccinated after a case of small-pox had developed in a house in Glasgow.

After some days one of them sickened, and an abortive eruption of small-pox appeared. These facts show that the virus of small-pox had been imbibed, but as it lay twelve days dormant, while the vaccine virus became constitutional on the eighth day, the vaccine had four days' start, so to speak, and the woman escaped from what would have been a very severe attack, with a few blighted papules.

Hydrargyrum Formidatum.

In a former issue we referred to this drug as the new Russian treatment for syphilis. We now learn from *Petersburg Med. Woch.*, that it has been tried at the Rochus Hospital, Buda-Pesth, and has by no means answered the expectations held out. First of all, it is excessively painful in its employment, and few patients can be induced to go on with it, and great local irritation is produced by the injection. Moreover, in no respect does it possess any advantage as an anti-syphilitic over other means already in use.

Rupture of Sciatic Nerve Mistaken for Fracture of the Neck of the Femur.

In the *Berlin Klin. Woch.*, Dr. Küster relates a case of this nature in which the mistaken diagnosis had been guardedly made by two physicians. Absence of crepitus and pain upon passive movement caused Dr. K. to diagnose rupture of the sciatic nerve (the symptoms were intense pain on pressure, most severe in the neighborhood of the hip-joint, outward rotation of limb, and apparent shortening, coming on after a fall), which was confirmed by the subsequent conduct of the case.

Spontaneous Formation of Gas in Bladder.

It would seem that sometimes, in patients suffering from diabetes, a species of vinous fermentation takes place in the saccharine urine, causing the liberation of gas. So, at least, does Dr. F. Guiard (*La France Médicale*, February 10-13, 1883,) endeavor to account for the peculiar phenomenon he has now observed in several such cases, viz., the discharge per urethram of gas, sometimes with an audible report. He proposes to call this condition *diabetic pneumaturia*.

A Rapidly Successful Treatment of Erysipelas.

In the *Lancet*, April 21, 1883, Dr. N. O'D. Parks relates a case rapidly cured by the application of a thick coat of white lead paint, enveloping the limb in cotton-wool, and giving one drachm of the tincture of perchloride of iron daily, in divided doses. The patient was six years old.

Three Prescriptions for Habitual Constipation.

The following are recommended by Dr. J. Mortimer Granville in the *British Medical Journal*, May 26, 1883:

When there is a lax and torpid condition of the muscular coat of the alimentary canal, evidenced by flatulence, etc., he uses the following:

R. Sodæ valerianatis,	gr. xxxvj.
Tincturæ nucis vomicæ,	℥℥.
Tincturæ capsici,	℥℥iij.
Syrupi aurantii,	iss.
Aquâ ad.,	3vj.

Misce, fiat mistura, cujus sumatur cochleare magnum ex aquâ ter die semihorâ ante cibum.

When there is a deficiency of glandular secretions, generally, throughout the intestine, manifested by a peculiarly dry and earthy character of the dejecta when the bowels *do* act, he gives:

R. Aluminis,	℥ij.
Tincturæ quassiæ,	℥j.
Infusi misturæ,	3vj.

Misce, fiat mistura, cujus sumantur cochlearia duo magna ter quotidie, post cibum.

The third form, which depends chiefly on interruption of the natural habit of periodic discharge, often results from repeated failure to move the bowels, in consequence of one or other of the two preceding forms of this trouble. This may generally be relieved by directing a perfectly regular attempt to go to stool, and by the use of the following draught, taken the first thing after *rising* from bed—not on awaking—in the morning, as nearly as possible at the same hour. It will be observed that it is not an aperient in the ordinary sense of the term. It is, as a rule, neither necessary nor desirable to continue it for longer than a fortnight. In most instances, it will be found to re-establish the normal habit in a week or less.

R. Ammoniæ carbonatis,	℥j.
Tincturæ valerianæ,	℥j.
Aquæ camphoræ,	3vj.

Misce, fiat mistura, capiat partem sextam in modo dicto.

Nephrectomy.

Dr. J. Knowsley Thornton reports three successful cases in the *Lancet*, May 26, 1883. He concludes his report by saying:

"The three cases taken together seem to me to demonstrate the advantage of the lateral over the median incision. The perfect suitability of the abdominal operation to all cases in which nephrectomy and not mere nephrotomy is the end aimed at; the capability of the peritoneum to dispose of large quantities of effused fluid under aseptic conditions, without the aid of the drainage tube, and without serious constitutional disturbance arising

from the absorption of the effused fluids, even after the removal of such an important eliminator as the kidney. The great differences in the ages of the patients, seven, twenty-six, and fifty-eight, and the varying diseases for which the operations were performed, make the records of especial value. The operation of Langenbeck with the extra-peritoneal treatment of the bladder end of the ureter, seems so surgically perfect, that I can not conceive any case presenting itself in which I should care in the future to face the difficulties and uncertainties of the loin incision. Indeed, I should be inclined to recommend an exploratory incision by the lateral abdominal section, with careful Listerian precautions, in any case in which it was of importance to thoroughly examine the kidney and ureter."

Subinvolution of the Uterus.

A very valuable lecture on this subject by Dr. Clinton Cushing, of San Francisco, is to be found in the *Med. News*, June 2, 1883. He considers premature assumption of domestic duties after parturition as one of the most frequent causes of this unfortunate condition, and he formulates the following sound advice to physicians:

"If it is possible to do so, I know of no better investment of time and money than for a woman who is raising a family to devote at least a month following her delivery to rest and quiet, and as free from excitement of any kind as may be. Unless she is confined to her bed by poor health, it is the only opportunity a mother of a family has to remain quiet long enough to get really rested; and I would advise you to inculcate, in the most thorough manner, the minds of your puerperal patients with the idea that a full month must be given up to rest and recuperation after delivery, and that a portion of each day after getting out of bed must be spent upon a lounge or couch for several weeks. Of so much consequence do I consider this advice, that I would again urge you to use all your eloquence to show your patients the advantages to be derived from a month's bodily and mental rest following confinement.

Solution of Vesical and Renal Calculi.

Before the Harveian Society of London (*Lancet*, May 26, 1883), Dr. Broadbent read notes of two cases illustrating the solution of vesical and renal calculi—one renal, the other vesical—which had yielded to treatment by large doses of alkaline salts. The first case was that of a man, aged fifty-five, who after an attack of renal colic de-

veloped characteristic symptoms of vesical calculus. He was ordered a mixture of an ounce of citrate of potash and half an ounce of acetate of potash, one drachm of these salts mixed to be taken three times a day, with a dessert-spoonful of succus taraxaci, in a quart bottle of salutaris water, the latter being selected as the vehicle, as it was stated to be simply distilled water aerated with carbonic acid. After persevering with this plan of treatment for a month, with no interruption to his business pursuits, the patient passed a small calculus, which, though of course it was impossible to say how far it had been reduced in size, bore marks of erosion from the solvent action of the urine; immediate relief was afforded the patient from his symptoms, and he had remained perfectly well since.

Scarlatina Evolved From Diphtheria.

The interconvertibility of zymotic diseases has not received the attention which it deserves. No less an authority than Dr. W. B. Carpenter believes in it (see vol. 47, p. 546), and now Dr. John Meredith furnishes additional proof in the *Lancet*, May 26, 1883. He relates a case of diphtheria, the *Simon Pure* disease, occurring in one member of a family; after a while a second one, who was exposed to the contagion, contracted a scarlatini-form disease, and subsequently a third person, who came much into contact with the second, developed a typical case of scarlatina. Whether all zymotic diseases are due to an identical poison, their differing manifestations being due to the peculiarities of the soil upon which they drop, we do not know; but we do know that the evolution of zymotic diseases is a field full of interest for the acute and intelligent observer.

Belladonna, a Prophylactic Against Scarlet Fever.

Dr. Owen Pritchard thinks he has discovered a prophylactic. As soon as one member of a family was taken with the disease, all the children in the house between the ages of six months and fourteen years were at once ordered to take the tincture of belladonna, in doses of from one to three minims, according to age, three times daily. It was thus given to twenty-eight families numbering seventy-four children, of which only four, or a percentage of 5.4, took the fever; while among those similarly exposed, and to whom belladonna had not been given, the percentage of sufferers was 36.2. It is only fair to state that the ordinary antiseptic precautions, with isolation, etc., were followed indifferently in all cases. This observation is made in the *Lancet*, April 14, 1881.

Specimens of Renal Carcinoma.

Before the Midland Medical Society (*British Medical Journal*, March 24, 1883).

Dr. Windle showed a large deposit of carcinoma in a left kidney, secondary to scirrhus mammae of two and a half years' duration, the patient being a female, aged 62. This was the only secondary deposit existing. After removal of the breast, very little urine was passed, and none at all the day preceding death. The fatal termination occurred six days after the operation.

The Swallowing of a Silver Half-dollar.

A peculiar case is that described by Dr. C. E. Webster in the *Boston M. and S. Jour.*, May 31, 1883. The coin lodged transversely in a vertical plane, so that a sound could pass it without obstruction, thus giving rise to the opinion that it had passed on into the stomach. The patient died from hæmatemesis, the result of two small ulcerations and consequent perforations into the aorta at the site of lodgment of the coin.

Aneurism of Anterior Communicating Artery.

In presenting a case to the Medico-Chirurgical Society of Montreal (*Medical News*, March 3, 1883), Dr. Osler called attention to the fact of the frequency of aneurism of the cerebral vessels, and to the fact that many cases of apoplexy in young persons were caused by them. This was the eighth instance which had come under his observation in the past few years.

Subcutaneous Injection of Quinine.

The following solution when injected hypodermically has frequently proven of service in obstinate cases of neuralgia; it should be injected close to the painful point:

R. Quinæ bromhydrat,	1 gram.
Æther. sulphuric,	8 grams.
Sp. vini rect.	2 grams.
M.	

Each cubic centimeter of this solution contains ten centigrams of the quinine salt.

Axillary Aneurism.

Dr. Little reports a case in the *Lancet*, May 19, 1883. The subclavian was reached by an infra-clavicular incision and ligated in its third stage. A perfect cure resulted.

A New Styptic.

Dr. Hill, of Goldsboro, told the Medical Society of the State of North Carolina, at its last meeting, that he had used ambrosia trifida, or rag-weed, in

epistaxis, pulmonary and uterine hemorrhage, hemorrhage from the bowels, hemorrhagic diathesis, etc., and found it of great value.

Nitrite of Amyl in Uræmic Asthma.

Dr. Thomas Sanctuary adds his testimony to its efficacy. His case is reported in the *Brit. Med. Jour.*, May 19, 1883. Like the other cases reported, relief was experienced from it, but finally, the patient was seized with a paroxysm, and died before the amyl could be used.

Abdominal Sanguineous Cysts.

Dr. J. S. Bristowe describes two cases in the *Lancet*, May 5, 1883, of abdominal cysts (in the male) containing a sanguinolent fluid. Tappings gave temporary relief, but the sacs filled again and again, and both patients finally died. The author cannot offer any explanations.

Permanganate of Potash vs. Carbolic Acid.

Dr. C. Roberts believes that a solution of the permanganate forms the most delicate test of the asepticity of sponges, as it leaves a brown mark on any collection of organic matter, so that in the *Brit. Med. Jour.*, May 5, 1883, he recommends this as a test of their purity, after washing in carbolic acid.

An Obstetrical Phenomenon.

In the *Lancet*, May 26, 1883, Dr. G. Yeates Hunter reports the case of a Hindoo woman in which placenta prævia, with shoulder presentation, occurred twice in the course of nine months. On each occasion version was performed, a dead child delivered, and a rapid recovery followed.

CORRESPONDENCE.

Eclampsia.

EDS. MED. AND SURG. REPORTER:—

Dr. E. Michener seems not to agree with my axioms.

1st. Bleeding must be done for effect, always very freely. I agree with him, for I am an old fogey on the subject of bleeding—believe in it in pneumonia, apoplexy, and all evident congestions of the great organs.

2d. Immediate and unconditional forced delivery. Premising that the operator *knows* enough about anatomy, turning, use of the hand and instruments, to make it safe: if not—not. All physicians of experience have seen cases ending with success where (with all knowledge of the curve of the pelvis) the full power of not one, but two,

was required to succeed. The doctor need not shudder. I think it is still the rule. Within a week I delivered a woman, Irish, primipara, 40 years old, with forceps, using all my power of traction, and a fat nurse into the bargain. No rupture of the perineum, œdema or malaise, except two or three days' retention of urine, and didn't wait twenty-four hours for *nature* to use up the patient.

3d. If the doctor has not seen a return of consciousness between convulsions, I think many have where *chloroform* was not used. I protest against the doctrine that the use of veratrum will be safe without bleeding in eclampsia, as a doctrine dangerous to life and false from teachings of the past. Phlebotomy, too, is safer, even in exceptional cases, than anodynes or anæsthetics. This terrible prejudice against opening a vein is merely the result of the insane cry of quackery, or the semi-medical education of our schools.

H. LEE BURRITT, M. D.

Bridgeport, Conn., June 12, 1883.

Urinary Examination.

EDS. MED. AND SURG. REPORTER:—

Having been constantly engaged in the examination of urine during the past four years, it has occurred to me that many physicians must find it inconvenient to make *thorough chemical and microscopical urinary examinations*, in consequence of the great amount of time required. I beg to announce, therefore, that I am prepared to make such examinations in the most careful manner, and to furnish promptly a written report of the results. A moderate fee will be charged. The examinations will be made at the University Hospital, and specimens may be sent directed to me at that place, or to 1811 Spruce street.

JUDSON DALAND, M. D.,

Assistant Curator to the University Hospital.
Philadelphia, June 15, 1883.

NEWS AND MISCELLANY.

Massachusetts State Medical Society.

At the one hundred and second annual meeting of this Society, held in Boston, June 12 and 13, the following papers were read:

"A Contribution to the Study of the Tubercle Bacillus," Dr. H. C. Ernst, of Jamaica Plain.

"The Use and Abuse of Ergot," Dr. G. L. Woods, of Springfield.

"The Use and Abuse of Ergot," Dr. W. A. Dunn, of Boston.

"Glykogen," Dr. J. W. Warren, of Boston.

"Phlyctenular Disease of the Eye," Dr. O. F. Wadsworth, of Boston.

"Minor Injuries of the Spinal Cord," Dr. B. Hartwell, of Ayer.

"Plumbing Appliances," Prof. T. M. Clark, Institute of Technology, Boston.

"Recent Changes in the Methods of Medical Instructions," Dr. E. N. Whittier, of Boston.

"Neurasthenia, Its Causes and Its Home Treatment," Dr. J. S. Greene, of Dorchester.

"The Artificial Feeding of Infants," Dr. J. W. Spooner, of Hingham.

"The Early Symptoms of General Paralysis of the Insane," Dr. W. B. Goldsmith, of Danvers.
 "The Annual Discourse," Dr. Amos H. Johnson, of Salem.

OFFICERS FOR THE ENSUING YEAR.

President—Alfred Hosmer, M. D., of Watertown.
Vice President—Ira Russell, M. D., of Winchendon.
Treasurer—Frank W. Draper, M. D., of Boston.
Corresponding Secretary—C. W. Swann, M. D., of Boston.
Recording Secretary—F. W. Goss, M. D., of Roxbury.
Librarian—David H. Hayden, M. D., of Boston.
Orator for Anniversary in 1884—John Crowell, M. D., of Haverhill.

The Depopulation of France.

This question is commencing to alarm the authorities. At a recent meeting of the Chamber, a deputy gave the following as the reasons:

1. Because the people have a dislike to emigrate, the Government having done nothing to encourage it.
2. Because the people are not kept enough in the country, and that the taxes are too high.
3. Because the Government does not restrain enough prostitution, and does not encourage marriage amongst the poor.
4. Because the consumption of tobacco and absinthe are attaining enormous proportions, so that the race is becoming weakened and stunted in intelligence and physique.

One of the most distinguished French economists, Beaulieu, said recently: "If the morals do not change in France, in fifteen or twenty years the population will have an excess of deaths over births."

A bill was introduced which contained two clauses calculated to check this depopulation. The first provides for a decrease in the taxes for every family which has more than four children; while the other proposes a bounty for every child above four where the parents paid no taxes.

An Anomaly in Hearing.

Dr. James C. L. Carson relates this unusual case in the *Brit. Med. Jour.*, May 26, 1883:

Mr. W. Harshaw, of Coleraine, consulted me about his ears. He was so thoroughly deaf that he could not hear a word that was said to him. He could not even hear the noise from the firing of a cannon. On examination, I could find nothing wrong with his ears; but in the course of the investigation, I made a most extraordinary discovery. Although he could not hear any sound which came through the air, he could hear the sound from a mouse running on the floor. I asked him to go to Edinburgh to show himself to Sir Charles Bell, Dr. Abercrombie, and Dr. Alison. He did so, and they kept him under daily examination and observation for ten days. They wrote to thank me for having given them an opportunity of seeing such a remarkable case, but they could not in any way account for it, and they thought there was no similar case in the records of the world. I wrote to suggest that it went to prove that the nerve of hearing, in place of being

a single organ, was double; and that one portion was for hearing through the air, and the other for hearing through the body by a sort of touch.

Medical Society of the State of Delaware.

This Society met in Wilmington June 12. Drs. Howard Ogle and Willard Springer, Wilmington, acted as president and secretary pro tem. Members of the Pennsylvania State Medical Society, J. J. McFerran, L. K. Baldwin, and M. O'Hara, who were present, were invited to participate in the deliberation of the meeting. The Committee on Application for Membership reported in favor of admitting the following persons as members of the society: H. B. Mitchell, J. P. Burwell, Charles Green, Thomas H. Keables, J. D. W. Temple, W. N. Wood, H. T. Persing, John Palmer, Jr., A. Lawber, James Stevens, Michael J. Hughes, Samuel W. Murphy, H. Collins, J. W. Short, and Francis W. Gum, and they were elected.

OFFICERS FOR THE ENSUING YEAR.

President—Robert M. Hargadine, M. D., of Felton.
Vice-President—Willard Springer, M. D., of Wilmington.
Secretary—George W. Marshall, M. D., of Milford.
Treasurer—J. W. Sharp, M. D., of Camden.

New Jersey State Medical Society.

The one hundred and seventeenth annual session of the Medical Society of New Jersey, the oldest association of the kind in the United States, was held at Atlantic City, June 12th and 13th. The following officers were elected for the ensuing year:

President—Stephen Wickes, M. D., of Orange.
Vice-Presidents—P. C. Barker, M. D., of Morristown; Joseph Parrish, M. D., of Burlington; Charles J. Kipp, M. D., of Newark.
Corresponding Secretary—William Elmer, Jr., M. D., of Trenton.
Recording Secretary—William Pierson, M. D., of Orange.
Treasurer—W. W. L. Phillips, M. D., of Trenton.

Standing Committee—Drs. T. J. Smith, of Bridgeton; Samuel S. Clark, of Belvidere; E. J. Marsh, of Paterson.

The next meeting will be held at Cape May, on the second Tuesday in June, 1884.

Sanitary Conventions in Baltimore.

At a recent meeting of the Maryland State Board of Health, on motion of Dr. Chancellor, it was decided that hereafter sanitary conventions or meetings be held at least once a year, under the auspices of the Board, in different parts of the State, with a view to promote a general interest in sanitary science; that the first meeting be held in Baltimore on the fourth Tuesday in October, 1883, and that a committee, consisting of the President and two members of the State Board, the President of the City Board, the President and Secretary of the Medical and Chirurgical Faculty of Maryland, and five citizens be

appointed to consider the best means of holding the convention, that prominent sanitarians throughout the country be invited to take part in the convention, and that manufacturers and dealers in sanitary appliances be invited to forward their goods for exhibition at the meeting.

Medical Registration.

A remarkable instance of the utility of legal enactments making the registration of physicians compulsory, has recently occurred in Wheeling, W. Va. A quack went to that city and started out with a most glaring and ingenious scheme of advertising, among which was the publication of an obscene journal called "Health and Home." The Board of Health were soon after him, and as he could not produce a satisfactory diploma or certificate, they refused to register him. After delaying the Board by various pretexts, he finally hastily packed up and decamped, just in time to avoid arrest.

Publication of the Formulæ of Proprietary Medicines.

At the last meeting of the Connecticut Medical Society, upon motion of Dr. Chamberlain, it was voted that the Secretary memorialize the Legislature on behalf of this Society, for the passage of a law requiring that no patent or proprietary remedy shall be sold in this State, unless the formula of its construction be plainly printed on the label; that there shall be a heavy fine for evasion of this law, and if analysis shows any considerable difference from the alleged formula.

Death from a Fall on a Needle.

La Presse Médicale reports a curious accident, resulting in the death of a little girl, three years of age. The child had picked up a needle, and was running with it to her mother, when she fell upon the needle, which penetrated the fourth intercostal space, the eye of the needle alone remaining outside the wound. The mother withdrew it by means of her teeth, but the child died before medical aid could be obtained, probably from internal hæmorrhage, which, gradually pressing upon the lung, brought about extreme dyspnoea.

California State Medical Society.

OFFICERS FOR THE ENSUING YEAR:

President—Ira E. Oatman, M. D., of Sacramento.
Vice-Presidents—Drs. W. S. Thorne, of San José; R. K. Reid, of Stockton; W. F. McNutt, of San Francisco; R. H. Plummer, of San Francisco.
Treasurer—Dr. F. W. Hatch, of Sacramento.
Permanent Secretary—Dr. Wallace A. Briggs, of Sacramento.
Board of Censors—Drs. Geo. W. Davis, C. A. Kirkpatrick, C. Cushing, A. G. Anthony, G. G. Tyrrell.

Medical Society of North Carolina.

The following are the officers for the ensuing year:

President—Dr. A. B. Pearce, of Weldon.
First Vice-President—Dr. F. W. Potter.
Second Vice-President—Dr. Geo. W. Graham.

Third Vice-President—Dr. R. Dillard.
Fourth Vice-President—Dr. Geo. W. Long.
Treasurer—Dr. A. G. Carr, of Durham.
Secretary—Dr. L. J. Picot, of Littleton.

The Suez Canal a Sanitary Nuisance.

The Suez Canal is in a fair way of becoming an open and stagnant sewer. The stations on its banks are drained into its waters. It is never flushed, there is no tide, and the stench is becoming intolerable. Diarrhoea and sickness prevail in vessels detained in the canal, and as detentions are increasing in number and duration, the matter is becoming serious.

Sanitary Progress in New Zealand.

The medical officer of health for Christchurch District points, in his annual report for 1882, to a rapidly diminishing mortality. In 1875 it amounted to 30.4 per 1000; in 1879 20.1, and in 1882 only 13.7. This great lowering can be directly traced to sanitary improvements.

Officers of the New York Neurological Society for 1883.

Dr. Wm. J. Morton, President; Dr. L. Weber, First Vice-President; Dr. Farrington, Second Vice-President; Dr. M. J. Roberts, Secretary; Dr. M. Putnam-Jacobi, corresponding Secretary; Dr. E. C. Harwood, Treasurer.

The Royal Red Cross.

Such is the title of a new order for women, who have done good service in civil or military hospitals, while nursing the sick and injured, that has been instituted by the Queen of Great Britain.

Personals.

—Lüer, the famous instrument-maker of Paris, has recently died.

—Dr. Julius Althaus, of London, has been elected a Corresponding Fellow of the New York Academy of Medicine.

—Prof. Ellerslie Wallace has resigned the Chair of Obstetrics and Diseases of Women and Children in the Jefferson Medical College, on account of ill-health.

—According to a London city missionary in Westminster, the Duke of Westminster has closed no fewer than twenty-four public houses on his Grosvenor Square estate within the last five years. He had closed thirteen others previously. Of the twenty-four still remaining several are already doomed, as the Duke will not renew the leases for their continuation as public houses.

Items.

—Salicin in half-drachm doses every two hours is said to relieve acute coryza.

—M. Vulpian, as the result of numerous experiments with tuberculous virus, recommends sulphurous acid as the most powerful destroyer of its specific properties.

—The summer resorts of North Georgia will be re-opened this year with increased accommodations. Many Southerners who formerly visited Northern resorts will go there.

—The manufacture of patent medicine in the United States involves a capital of ten and a half millions, and produces mixtures valued at fourteen and a half millions annually.

—The Municipal Council of Paris has voted a sum of 3,000f. for the year to organize a pharmaceutical night-service for Paris on a basis similar to the present night-service of physicians and midwives.

—A Lexington, Ky., doctor hangs out the following sign: "Dr. Tooles, scientific carver of toes and limbs; specialist and expert in removing rheumatism; corns and cramps extracted according to nature."

—Prof. Huxley says that the presence of a rat in the house always indicates a connection with a sewer. This will surprise many persons who don't live within ten miles of a sewer, and are troubled with rats.

—Dr. I. H. Morton reports, in the *British Medical Journal*, May 12, 1883, a case of hydrocele radically cured by the injection of two drachms of the spirituous extract of ergot. Very little pain and but slight inflammatory action followed.

—"You may say what you please," remarked the old doctor; "physicians are not all humbugs. There are some honest men among them." "Unfortunately, yes," replied Fogg; "of course you refer to their patients, doctor."—*Boston Transcript*.

—Mrs. Carter, of Bellair, Ohio, says in her application for divorce that her husband compelled her to swallow spoons, buttons, long strings of wrapping-yarn, and marbles, as punishment for smiling at other railroad men as they passed the house.

—For a long time official circles in London have been agitated over the question whether or not a woman should be appointed to be superintendent of the female employes in the post-office. It has at last been decided by the appointment of a woman physician.

—It is proposed to erect a Swiss Hospital and Home in New York city. The enterprise is under the management of the Swiss Benevolent Society, which already has five thousand dollars for the object. The Swiss in New York number between twelve and fifteen thousand.

—A bill to prevent the manufacture and sale in this State of the "toy" pistol was presented to the Legislature recently. Another bill was introduced allowing the killing of English sparrows at all times. Now if the English sparrows could only be taught to play with toy pistols, all sides would be satisfied.

—A cabman, convicted at the Marlborough street police court for being drunk and incapable while in charge of his cab, and fined 20s., assured the magistrate, in his defense, that it all arose through the folly of attempting to be one's own doctor. He thought the remedy for the complaint he was suffering from was stimulants, but he no doubt had prescribed for himself too much.

—Persistent war continues to be made in Cincinnati upon Italian fruit venders who sell decayed or frozen bananas. Heretofore they have been fined \$5 and costs upon conviction, but Judge Higley says that offenders hereafter brought before him will not be dealt with so leniently.

—There is an earnest attempt making to root out the terrible disease of leprosy from the Hawaiian Islands. Fifty lepers have recently been removed from Honolulu to the leper settlement at the island of Molokai, to be separated from their friends and families forever.

—The Chinese papers state that Li-Fu-Yen, wife of the ex-Viceroy of the province of Chilli-le, being seriously ill, her husband had sent for "Miss Dr. Howard." It is added that this lady, who appears to be established in Peking, is obtaining a good practice among the titled ladies of China.

—The latest instance of the utilization of waste products is that effected at Elk Rapids, Michigan, with the gaseous matter given forth by a blast furnace in which are manufactured fifty tons of charcoal iron per day. In the case to which we refer, the vast amount of smoke from the pits formerly lost in air is now turned to account by being driven by suction or draught into stills surrounded by cold water, the result of the condensation being first, acetate of lime; second, methyl alcohol; third, tar; the fourth part produces gas, which is consumed under the boilers. Each cord of wood produces 29,000 cubic feet of smoke; 2,900,000 feet of smoke is handled every 24 hours, producing 12,000 pounds of acetate of lime, 200 gallons of alcohol, 25 pounds of tar.—*Stearns' New Idea*.

QUERIES AND REPLIES.

Subscriber.—The salary varies on the different lines. The appointments are made by the directors of the companies.

MARRIAGES.

CRAMPTON—MARLING.—On Tuesday, June 5, 1883, at the Fourth Street Presbyterian Church, New York, by Rev. F. H. Marling, pastor, Henry E. Crampton, M. D., to Ellen Eliza, daughter of the officiating minister.

DISBROW—COUSE.—On Wednesday, June 13, at the residence of the bride's father, Newark, N. J., by the Rev. James Montgomery, E. Clarence Disbrow, M. D., of Toms River N. J., to Evalena L., daughter of E. M. Couse.

FRAER—WILLIAMS.—June 7, at the residence of W. H. Clement, Esq., Morrow, O., by Rev. E. T. Swiggett, Dr. J. M. Fraer, of Chattanooga, Tenn., to Mrs. Julia S. Williams, of Cincinnati. No cards.

HASBROUCK—SEWALL.—On Wednesday, June 6, at Dobbs Ferry, New York, by the Rev. D. L. Marks, Joseph Hasbrouck, M. D., to Mrs. Ellen M. Sewall, daughter of the officiating clergyman.

KING—NORRIS.—On Tuesday, June 12, 1883, at St. Paul's Reformed Church, Mott Haven, by the Rev. Hasbrouck DuBois, assisted by the Rev. J. M. Sherwood and the Rev. Carlos Martyn, M. Eva Norris, daughter of David Norris, and Nathan S. King, M. D., both of this city.

REICHERT—WELSH.—On Thursday, June 7, at the country residence of the bride's parents, by the Rev. Joseph A. Seiss, D. D., Edward T. Reichert, M. D., and Marion C. Welsh, daughter of Henry D. Welsh.

DEATH.

LEVINGS.—In New York, on Sunday morning, June 10, 1883, Dr. Noah C. Levings, aged 59 years.

JENSEN'S CRYSTAL PEPSIN,

Strictly Inodorous and Tasteless, and Perfectly Soluble in Water without Acid.
(gr. j. of it will dissolve the boiled whites of two or three eggs.) See advertisement on page 10.

A NEW DISEASE OF THE NASAL CHAMBERS NOT NOTICED BY PROF. HARRISON ALLEN.

BY W. STUMP FORWOOD, M. D.,
Of Darlington, Md.

As sentinels upon the watch-towers of the profession, it becomes the duty of every member thereof to give warning of the approach of error, in whatever guise it may appear, and to be especially watchful when it presents itself in the robes of high authority.

Within the last ten years two new causes of disease have been introduced into this—Harford—county, by new industries, established within the decade. One of the diseases referred to results from operating in *flint mills*, where the flint-stone or rock is reduced to a fine powder, which is used in the manufacture of porcelain ware, the ordinary table ware. The operatives exposed to the inhalation of the flint dust in these mills for a length of time, die of a pulmonary disease similar to, and might very readily be mistaken for, pulmonary consumption. We made a brief report of this very fatal disease in the columns of the MEDICAL AND SURGICAL REPORTER, some five or six years ago—the date not now remembered.

The object of the present article is to note a disease which is produced in the operatives who are connected with a particular department of the *canning* industry. We refer to the canning of fruits and vegetables, which industry is more extensively carried on in Harford county, Md., where dozens of establishments are in active op-

eration, which prepare millions of cans annually for the markets of the world, than, we are informed, in all other parts of the United States combined. These goods are put up in tin cans, varying in capacity from two to three pounds, corn being usually put up in two-pound cans, and tomatoes in three-pound cans. A considerable number of hands are required to be employed in the various processes of canning. The cans containing the fruits before they are immersed in a cauldron of boiling water, are hermetically sealed by the “capper” with solder. *Muriatic acid* is used with the soldering material, and when the hot iron is applied, the fumes arise to the “capper’s” face and *nostrils*. This is the source of disease, and, so far as we are aware, is a cause that has not been noted in medical literature. Certainly it is a cause that is unknown to so high an authority as Dr. Harrison Allen, Professor of Physiology in the University of Pennsylvania. In an instructive paper by Dr. Allen, entitled “*Abscess, Ulceration, and Necrosis, as met with in the Nasal Chambers*,” recently—May 26, 1883—published in the MEDICAL AND SURGICAL REPORTER, he states unqualifiedly, in speaking of the causes of perforation of the *septum nasi*, after excluding the congenital openings, saying: “The acquired perforations are always syphilitic, and co-exist with other signs and symptoms of this disease.” Vol. xlviii. p. 575.

I feel sure that no one will be more gratified than Dr. Allen himself in having a statement of facts that will contradict this sweeping assertion; a statement that will protect some innocent individuals from the charge of contamination with so dreadful a “disorder.”

The constant inhalation of the fumes of muriatic acid, associated, as they are, with the lead solder, which the busy capper neglects to protect himself against, soon produces inflammation of the mucous membrane of the nose, which finally results in ulceration. With some patients, after the removal of the cause, and the application of proper treatment, recovery takes place after two or three months; but with those who have a scrofulous taint in their constitutions, this ulceration is exceedingly intractable; and in spite of all treatment proceeds for months, and even years, until the septum is finally perforated. And, strange to say, it is the common experience of those who have suffered, that as soon as perforation takes place, all the soreness and consequent annoyance disappears without treatment, and the patient recovers—with, of course, a permanent opening in the nasal septum.

There are several of such cases now in this vicinity, which present positive evidence that ulcerated perforations of the septum nasi may exist in individuals who have never suffered with syphilitic disease, either from personal exposure or inheritance.

The finger-ends and finger-nails are often chronically injured in those who work with the muriatic acid and solder. The matrix of the nail becomes diseased in the manner of an intractable "run-around," as it is commonly called; and this condition will often resist all treatment for months.

It is evidently the poison by the *lead* which maintains the ulcerations produced by the more active irritant, muriatic acid.

This irritation of the nasal passages that the cappers suffer with, is often the result of carelessness and ignorance. By the exercise of a little care in keeping to the windward of the fumes, and by anointing the nose thoroughly, internally and externally, several times daily during exposure, with mutton tallow, or other oleaginous substance, the irritations spoken of, and the consequent perforations, may be avoided.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, May 10, 1883.

Vice-President F. P. Henry in the chair.

Tympanic Caries Producing Sub-dural Abscess, Opening into Lateral Sinus.

Nell D., aged 18, was admitted into Prof. Agnew's ward in the Pennsylvania Hospital, with the following history: When he was five years of

age he had measles, and since that time he has had suppuration of the right middle ear. It discharged at intervals. Two weeks previous to admission he had acute pain in his right ear, and a week later it began discharging. He had severe headache ever since he was first attacked. The pain was situated principally towards the front, but existed also towards the sides of the head. The discharge was profuse and offensive. He was emaciated, his face was haggard, pale, with a slightly yellowish tinge, he had an anxious expression of countenance, and altogether looked very bad. His mother says that this change occurred entirely in the two weeks prior to admission. The ear was cleansed, and astringents applied; the discharge ceased in about six days. Bromide of potash failed to relieve the headache, but morphia hypodermically gave temporary relief. He held his neck stiff, with the head slightly drawn back. This increased as the disease progressed. He had nausea, and later vomited large quantities of greenish-black fluid. Three days after entrance, the pains extended down the spine and into the legs, and to the under side of his arms. On the fifth day after his admission, the headache and pains in the lower extremities were very severe. The discharge had almost ceased. His temperature rose to 102.5°. An ice cap afforded no relief. On the eighth day he died.

	TEMPERATURE.		PULSE.	
	Morn- ing.	Even- ing.	Morn- ing.	Even- ing.
Day of entrance,	9—100°	103°	62	86
"	10—101.5°	101.5°	70	96
"	11— 98.5°	102.4°	66	80
"	12— 99.5°	100.8°	68	84
"	13—102°	102.5°	84	88
"	14—102°	105.4°	100	102 •
"	15—103.5°	102.5°	106	104
"	16—101.6°	102°	136	114
"	17— 99°	100°	112	108

His bowels moved regularly; they werenot constipated.

Post mortem examination made twenty hours after death. Skull was very thin at all points. Dura-mater apparently normal. Marked congestion of the arachnoid and pia mater, more so on the right side. No evidences of thickening or other disease. Brain normal. No excessive cerebro-spinal fluid.

Region of Right Ear.—Beneath the dura mater, covering the petrous portion of right temporal bone over the middle and interior ear, there was an abscess about an inch long. It communicated by a small opening with the tympanum. At its opposite extremity it opened into the lateral sinus. This was filled with pus from the point of opening to within two inches of the torcular herophili. These two inches were filled with a soft black clot. Below the point of opening to the jugular foramen, there was thick pus and a partly decolorized clot, much firmer than the one extending in the direction of the torcular herophili.

Remarks.—The congestion was active, not passive. It was most marked on the surface of the brain. The large veins were not distended, and there was consequently no excess of fluid.

The patient's mind was clear to the last. The

most marked feature of the case was the emaciation, which was very rapid. An interesting point in connection with the case is the cause of death. It seems to have been due to the entrance of pus into the circulation. In other words, it was probably a case of true pyæmia. He had two marked symptoms of pyæmia, the sallow countenance and the rapid emaciation; besides these he had the vomiting. He never had the slightest chill or the sudden rise and fall of temperature, both so marked in cases of pyæmia. Sweet breath and any external abscesses or lung affection were also absent. I was unable to examine the other organs.

Specimens (Lungs, Heart, and Kidneys,) from a case of Bright's Disease.

By Frederick P. Henry, M. D.

The organs upon the table were taken from a typical case of chronic parenchymatous nephritis. The kidneys are slightly enlarged, extremely pale, with marked arborescent vascularity of the surface, and with non-adherent capsules. In fact, they represent one of those instances in which the gross appearance suffices for diagnosis. The heart is slightly enlarged, its left ventricle dilated, its walls fatty and its valves competent. This heart gave rise to no murmur, strictly so-called, but did produce in typical degrees the sound called by Bouillaud and Potain the *bruit de galop*. Potain considers this sound to be diagnostic of interstitial nephritis; but, for my part, I have invariably encountered it in cases of Bright's disease in which the parenchymatous affection was predominant. The lungs are congested and oedematous throughout. The pleura is greatly thickened on both sides and the pleural cavities abolished, with the exception of the diaphragmatic portion of the right side, which contains a small amount of fluid in the shape of a number of serum-containing loculi. The cause of death was oedema of the lung, and the interesting question arises as to whether oedema of the lungs, which is so common an event in cases of Bright's disease, may not be favored by the obliteration of the pleural cavity also commonly present in these cases; or, in other words, and conversely, whether the pleural cavity may not serve as an outlet for effusions which, but for its presence, would infiltrate the lung parenchyma.

Although my attention has not been especially directed to the point which I have just raised, and therefore I have no cases other than that just reported to bring forward in its support, I think I can state, in general terms, that before oedema of the lungs occurs, in cases with open pleural cavity, that cavity contains a considerable quantity of fluid. That is to say, that its capacity to act as a drain to the lung tissue is exhausted, and it does not at all follow that, for this result to be produced, the pleural sac should be distended with fluid. In fact, it would seem that a moderate amount of fluid in the pleural sac may be sufficient to exhaust this conservative power, and this amount varies with the state of the pulmonary circulation. The view just advanced is in complete harmony with what we know of the physiological function of lymph spaces, among which the large serous sacs are reckoned. The last volume of our *Transactions* (Vol. X.) contains a paper

upon pleural effusions in which I argued at considerable length that any cause which interfered with a proper expansion of the thorax would lead to congestion of the pulmonary capillaries, thereby favoring pleural effusion. The results of capillary congestion vary in different systemic conditions. In Bright's disease, owing to the altered state of the blood, the result is oedema, that is, a serous infiltration of lymph spaces. Effusion into the serous investment of organs, such as the lungs and heart, is conservative, so far as concerns the parenchyma of these organs. The practical result of these considerations is that oedema of the lung, in cases of Bright's disease, is favored by pleuritic adhesion, and secondly, that oedema of the lung may perhaps be averted by the timely performance of paracentesis.

Myxomatous Tumor of the Subcutaneous Cellular Tissue of the Chest.

Presented by Dr. MacConnell.

The specimen was removed by Dr. Allis at the Jefferson Hospital clinic one week ago. The patient was a man aged 63 years, who stated that six years ago he had been struck on the side of the chest by a box, at a spot corresponding to the site of the tumor. The growth commenced shortly after this traumatism, and at the time of the operation was of the size of a pecan nut. The microscopical appearances were somewhat the same as those presented by the specimen presented for him by Dr. Nancrede, in December, 1882. The present specimen very beautifully illustrates the transitional stages of the fetal development of blood-vessels, such as budding, etc. Abundant yellow elastic tissue is also seen. The cells are but faintly stained with picro-carmin, owing to the highly refractive substance of the growth (mucin), rendering the coloring of the nucleus indistinct. Dr. MacConnell thought that the apparent rarity of similar growths was due to the use of alcohol for hardening purposes. If such a reagent be used, only the appearance of a young connective tissue growth will be detected.

The Green Box.

In his address at the recent meeting of the American Medical Association, Dr. John L. Atlee said:

Many of the elderly gentlemen present to-day must have heard of the much dreaded "green box." During the time of Drs. Rush and Barton, it was reported that favoritism was shown to their respective students, and the same was said of the students of Drs. Chapman and Dorsey. To obviate this, or the appearance of it, a large green screen was placed across one corner of the room, having a door behind it, through which the candidate entered, and here underwent his examination, unknown to any one but the dean of the faculty. This mode of examination was adhered to until after the death of Dr. Dorsey, when it was optional with the student to go into the green box or present himself openly before the faculty. Some ten or twelve candidates had such a terror of the green box, that they went to New York, where they obtained the degree of M. D., by undergoing an examination and paying the graduating fee.

EDITORIAL DEPARTMENT.

PERISCOPE.

Chloroma.

The *Lancet*, April 21, 1883, says:

Nearly fifty years ago Billroth is said to have described a form of malignant growth distinguished by a green discoloration, whence we derive the name of chloroma or "green cancer" (Billroth). There can be no question that the disease is of rare occurrence. In 1878, Huber (*Archiv. der Heilkunde*, xix.) was able to collect only seven examples. The tumors are not cancerous in the modern sense of the term, and so may best be described as chloro-sarcomata, or more simply, chloromata. Such tumors have been met with in connection with bones (e. g., the skull), but perhaps the chief centres of the lymphoid tissue of the body are the seats *par excellence* of tumors of a green color, this anatomical system having become involved in a secondary manner, or even having been the primary seat of disease. As an apparent example of this, we shall describe the main features of an interesting case recorded in Virchow's *Archiv.* for January, by Louis Waldstein. A man, aged forty-four years, by occupation a laborer, suffered from a short attack of "ague" many years before the commencement of his present illness. Without any assignable cause the symptoms of marked progressive anæmia set in rather suddenly. Satisfactory collateral evidence of the nature of the disease was not forthcoming; the urine, however, was noted to be of a green color, and there was rather high persistent fever. On the twenty-fifth day of the illness, the patient complained of pain on percussion of the sternum, and later also of some of the ribs. Gradual enlargement of the spleen and liver was detected by the ordinary methods. A great increase in the number of the white cells of the blood was first observed on the forty-first day of the illness; repeated observations negatived the existence of leucocythæmia before that date. Death followed in three days, on the forty-fourth day of the malady. At the post-mortem examination the mediastinal glands were found to be much enlarged, and colored green; the retro-peritoneal glands, and those of the portal fissure were also stained green. Although there were plugs of leucocytes in the hepatic capillaries, distinct areas of hyperplasia of the lymphatic tissues of the liver were not observed. It will be remembered that some investigators regard the white areas in the kidneys and liver of cases of leucocythæmia as extravasations from the blood-vessels. The spleen was enlarged, the Malpighian corpuscles being much overgrown. The medulla of the bones was red, and in many places of a greenish hue. Wherever the chlorotic tint was seen, the microscope revealed either a diffuse "coloration," or the pigment existed in granules in the protoplasm of the cellular elements. The green tint has been severally described as apple-green, grey-green, grass-green.

The results of chemical analysis have been by no means satisfactory. Huber thought the pigment was that of a fatty body, Balfour regarded it as biliverdin, Dressler suggested its identity with the coloring matter of greenish pus, whilst Dittrich has advanced the notion of its dependence on putrefaction. Waldstein is inclined to believe the colored pigment was derived from the coloring matter of the blood, and he points to its general presence in the morbid tissues, and to its passage with the urine as favoring his view. It is not at all improbable that every form of pigment occurring in the human body may ultimately be traced to one original source—viz., hæmoglobin.

The Radical Cure of Hay Asthma.

Dr. John O. Roe contributes an article on this subject to the *N. Y. Med. Jour.*, May 19, 1883, in which he reaches the following conclusions:

1. That hay fever is an affection not confined to age, sex, or condition in life.
 2. That it is excited by the pollen of flowers or grasses, dust, or other irritating substances floating in the atmosphere, which are brought, by inhalation, in contact with the nasal and bronchial mucous membrane.
 3. That the nasal mucous membrane in certain individuals is very susceptible to the irritating effect of these substances, while in others it is not.
 4. That this hyperæsthesia is associated with or occasioned by a diseased condition, either latent or active, of the naso-pharyngeal mucous membrane, and with an hypertrophied condition of the vascular tissue covering the turbinated bones and the lower portion of the septum.
 5. That the systemic disturbances, such as asthma, etc., are the effect of the local irritation of this diseased tissue in the nasal passages, which is reflected to the larynx, bronchi, and lungs, causing in them a fluctuatory hyperæmia, produced through the correlating function of the sympathetic ganglia connecting these different regions.
 6. That the treatment during the attack can only be palliative, such as to soothe the inflamed parts and to quiet the systemic disturbance which may be occasioned.
 7. That in most cases the only effective relief during the attack consists in going to a seaport or mountainous region, or to any locality where the air is free from the substance which produces the irritation.
 8. That curative measures can only be adopted when the individual is free from the attack.
 9. That the removal of the diseased tissue in the nasal passages removes the susceptibility of the individual to future attacks of hay fever.
- For the removal of this tissue, Jarvis' snare is the most efficient means of removing that at the posterior end of the turbinated bone, while that covering the middle and anterior portion is most reliably removed by the galvano-cautery.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

ANOTHER VOLUME.

This issue completes another volume of the MEDICAL AND SURGICAL REPORTER, and adds another six months to our already ripe age.

During our almost unequaled lengthy career as a medical journal, numerous younger brethren have been born into the world of medical literature, to all of whom we have and do extend the fraternal hand of good fellowship.

With age, we trust we have gained experience, and realizing that the *practical* doctor wants a *practical* journal—one that will aid him to *recognize* and *cure* disease—we have endeavored to furnish such; how we have succeeded, we leave for our subscribers to decide.

During the past six months our pages have contained 83 Original Communications, 33 Hospital Reports, 59 Society Meetings, 171 articles in the department of Periscope, 120 Editorials, 441 Notes and Comments, 51 Correspondence, to say nothing of a large and varied assortment of interesting *News and Items*.

To furnish still more of practical value shall be our constant endeavor in the future, and we shall aim so that any one who subscribes to the REPORTER and the *Quarterly Compendium*, will learn of everything of interest in the medical world.

Through the columns of these two journals all operations of any importance will be recorded, so that complete statistics can be made up from our pages.

Without going into details, we will simply repeat, that it is our intention to carefully peruse our enormous exchange list, and culling therefrom the practically valuable points, serve them up to our readers, well dressed and ready for immediate use. Our original department speaks for itself.

We will make the REPORTER in the future, as it has been in the past, *the* journal for the busy practitioner.

SANITARY ASSURANCE.

An organization has been recently formed in England for the purpose of examining into the sanitary condition of all houses offered for rent.

The great benefits of such an organization to

the large masses who do not own their dwellings must be immediately manifest, and the protection to life thus offered at a small cost is incalculable.

Commenting on this organization, Dr. Norman Chevers, comparing the sanitary condition of ancient Rome and modern London, referred to his experience in Calcutta, and urged that the sanitary condition of all large towns was such that no householder should be satisfied without the assurance of some competent authority that his dwelling, whether a palace or a cottage, was free from drain contaminations. He expressed an opinion that consumption was hereditary principally because successive generations neglected to remedy the sanitary defects from which their forefathers suffered.

VALUE OF EARLY OPERATIONS IN MORBID GROWTHS.

In. *Vol. XLVI.*, March 4, 1882, p. 243, we called attention to what Mr. Jonathan Hutchinson so aptly calls the "Pre-cancerous Stage of Cancer," and noted that he strongly advises early operation in all cases of suspicious tumors. Now, our distinguished Prof. S. D. Gross, in a paper read before the American Surgical Association, practically recommends the same thing. He seems to recognize a stage of malignant neoplasms in which there is, so to speak, an absence of malignity; and if we seize this early period to operate, we can do so with good hopes for non-recurrence.

Again, even though the morbid growth may be benign, yet at some future time its removal will be indicated when its growth has made its retention inconvenient.

It would seem, then, to be in accord with the teachings of good surgery, to perform *early* operations for the removal of all morbid growths, whether malignant or benign, unless some positive contra-indications exist.

CAMELS IN WAR.

Some curious experiments were recently made in the Zoological Park of Hagenbuch, at Ham-bourg. It was thought possible to use camels for

the transport of the wounded in the German army, and these experiments were instituted to decide the question.

A simple receptacle in wood covered with canvas was so constructed that it could be used with the ordinary camel or with the dromedary.

In case of urgency, a similar apparatus could be rapidly devised with muskets and the soldiers' overcoats.

The experiments gave excellent results; each animal could carry from two to four men, and, if necessary, an apparatus carried between two camels could be used.

FOREIGN CHARLATANS.

We are acquainted here in France (*Gazette Hebdomadaire*) with the American quack, high in color, loud in voice, noisy and impudent; with the Spanish charlatan, mystic, sombre, the crucifix in hand, always ready in prayer; with the paternal Dutch impostor, writing his consultations with a flask of urine in hand, as in the famous "Dropsical Woman" of Gerard Dow. But the German charlatan is of a different species; he is surrounded with piles and electric apparatus; he is a professor of occult physical science, who cures with the same spark pulmonary tuberculosis and cerebral debility. He is a professor, a distinguished lecturer, the apostle of a newly-discovered art. The Medical Society of Leipsic are about to take measures against two such individuals, one an ex-carpet-worker, now director of an electro-therapeutic establishment, and another, Hindorf, a professor of natural medicine.

NOTES AND COMMENTS.

Paraldehyde.

Dr. John Brown (*Brit. Med. Jour.*, May 19, 1883,) says that the hypnotic dose is from thirty to fifty minims. It does not produce headache, constipation, nor stomach derangement. Paraldehyde in some cases causes a peculiar burning taste in the mouth the following morning. The breath smells of the drug for several hours after waking. It is probable that nearly all the drug is got rid of by the lungs in the same way as it is taken. Paral-

dehyde is not much, if anything, superior to chloral. It costs \$1.25 per ounce; chloral, 12 cents per ounce; besides which, it requires a larger quantity of the former, so that it is about sixteen times as dear as chloral. Therefore it is not likely to come into general use. Being so insoluble in water, it makes rather a large draught, which is objectionable.

Unusual Tumor of the Breast.

Before the Cambridge Medical Society (*British Medical Journal*, May 19, 1883), Mr. Sheild showed a specimen of malignant tumor removed from the breast of a girl, aged 14, by Professor Humphry. The history could not be obtained, but it was probably of rapid formation. Under the microscope, it showed the characteristics of spindle-celled sarcoma. Such tumors were very rare at that age, and, from their soft brain-like consistence, might give one the idea of a collection of fluid; rapid recurrence was to be expected. The wound was kept open and made to heal by granulation, in the hope that suppuration might get rid of any sarcomatous cells that might remain about the base of the tumor.

On Transplantation of Skin-flaps from Distant Parts without Pedicle.

Dr. J. R. Wolfe removes all the cellular tissue from the lower surface of a skin flap, and then plants it where he desires, and it takes root and grows fast. By this simple procedure we can (he claims) do away with the inconvenient method of allowing the flap to remain attached to its original site until it has grown fast in its new home. In the *Practitioner* for May, 1883, he reports good success, and claims for himself priority in recommending this modification.

Malarial Pseudo-Epilepsy.

In the *Med. Times*, May 19, 1883, Dr. H. C. Wood relates a case of attacks of convulsions and unconsciousness somewhat resembling, though in many respects differing from, epileptic seizures. The patient had been subjected to malarial influences, and had unavailingly consumed large quantities of quinine. He was given twenty-five grains of quinine daily, tincture of the chloride of iron and arsenic with chloral at night, under which treatment he rapidly recovered.

Hæmatinuria.

Urine with a red, port-wine color, acid reaction, sp. gr. 1030, lots of albumen, but no blood cor-

puscles, were the obvious signs presented to Dr. Wm. H. Sutton (*Medical Herald*) in the case of a boy who had had chills and fever for months. Vomiting, anemia, temperature 100.5°, and pulse 138, completed the symptoms. Iron and gallic acid, followed by pepsin, morphia, and bismuth, gradually controlled the symptoms, and the boy made a recovery.

Malaria in Flower-pots.

Tending to corroborate the idea that malaria is caused by any vegetable decomposition is the case reported by Dr. Eichwald, of St. Petersburg, of a lady who lived constantly in a room filled with flowers in pots, and who thus acquired an intermittent fever with symptoms of true malaria.

Is the Spleen Necessary for Life?

Prof. Schuethauer, of Pesth, reports in the *St. Petersburg Med. Woc.* the post mortem upon a woman, aged seventy, where no spleen was found. The organ had not been destroyed by disease, but had never been present.

NEWS AND MISCELLANY.

The Medical Society of Washington Territory.

This society held its eleventh annual meeting in Seattle, June the 8th. At 10 a. m., the president called the meeting to order, and after the reading of the minutes of the previous meeting, the society listened to a most interesting report by the Secretary, Dr. C. H. Merrick, in which he reviewed the good already done by the society since its organization, and pointed out much that as yet remains to be accomplished. He showed that there were now about ninety regular physicians practicing in the Territory, and that the relative proportion of quacks was fast diminishing since the new act to regulate the practice of medicine has been in force. He also pointed out the need of both a Territorial and local Board of Health. The following physicians were then elected to membership:

Drs. A. J. Beach, J. C. Sundberg, Mary Brown, S. Whittemore and J. S. M. Smart.

Dr. Sundberg next read a paper on "The Hygienic Care of the Eye," and Dr. Weed read an interesting report on a case of "Diaphragmatic Hernia." A communication from the Eastern Washington Medical Society was read and referred to a committee. Means to raise the status of the medical profession throughout the Territory were discussed, and committees were appointed to carry out the various plans by which this could be accomplished.

The following were the officers elected for the ensuing year: Dr. E. L. Smith, President; Dr. C. H. Merrick, Vice-President; Dr. J. C. Sundberg, Secretary; and Dr. G. A. Weed, Treasurer. To constitute the Board of Censors, Dr. H. C.

Willison, of Port Townsend, Mary Brown, of Seattle, and C. W. Harvey, of New Tacoma were elected.

After a vote of thanks to the various transportation companies that had courteously reduced the fare for delegates to the society, and also to Drs. Smith & Willard for the use of their office, the meeting adjourned to convene again at Seattle, on the third Wednesday in June, 1884.

Mississippi State Medical Association.

The following are the officers for the ensuing year:

President—Dr. J. M. Greene, of Aberdeen.

Vice-Presidents—Drs. S. N. Walker, of Baldwin, and D. McCallum, of Westville.

Recording Secretary—Dr. W. E. Todd, of Clinton.

Assistant Secretary—Dr. J. F. Hunter, of Jackson.

Corresponding Secretary—Dr. M. S. Craft, of Jackson.

Treasurer—Dr. Robert Kells, of Jackson.

Judicial Council—Drs. W. D. Carter, J. M. Taylor, N. L. Guice, R. S. Toombs, B. F. Ward, S. V. D. Hill, J. P. Moore, W. Powell, and B. F. Kittrell.

Medical Association of Georgia.

The following are the officers for the coming year:

President—Dr. A. W. Calhoun, of Atlanta.

Vice-Presidents—Dr. R. J. Nunn, of Savannah, and Dr. M. P. Deadwiler, of Elberton.

Secretary—Dr. James A. Gray, of Atlanta.

Treasurer—Dr. E. C. Goodrich, of Augusta.

Additions to the Board of Censors—Dr. Eugene Foster, of Augusta, and Dr. J. S. Todd, of Atlanta. Macon is the place of meeting next year.

Professor Ellerslie Wallace's Successor.

The Trustees of Jefferson Medical College have elected Professor Theophilus Parvin, of Indianapolis, successor to Professor Ellerslie Wallace in the chair of Obstetrics and Diseases of Women and Children. Professor Parvin is a Delawarean by birth. His mother was the eldest daughter of Cæsar A. Rodney, the Attorney-General of the United States during President Jefferson's administration. He was last year President of the American Medical Association, and is at present a professor in the University at Indianapolis.

Items.

—San Francisco has one thousand physicians.

—A painter made a village chemist's sign read —"Physicians' prescriptions carefully confounded."

—The New Jersey State Legislature has passed a law forbidding any person, knowingly, to sell cigarettes or tobacco in any form to any minor under sixteen years of age.

—A case of polyorchism has been observed in Bulgaria, in a farmer eighteen years of age. There were three testicles, two being on the right in the scrotum, one above the other.

—A four years' graded course is soon to be introduced into the Medical School of San Francisco, and every student will have to take it as prescribed.

OBITUARY NOTICES.

NOAH C. LEVINGS, M. D.

Dr. Noah C. Levings died at his late residence, No. 47 West Ninth street, New York, June 12, of chronic Bright's disease of the kidneys. The deceased was born in Burlington, Vt., March 4, 1824, and was graduated at the Albany Medical College in 1841. He remained in Albany one year after his graduation, when he came to New York city and obtained his degree from the Medical Department of the University of the City of New York in 1843. He then opened an office on Spring street, and began the practice of his profession. In 1849 he went to California, holding the position of ship's surgeon on his outward voyage. He remained on the Pacific Slope six months. Returning to New York, he resumed his medical practice. He was married to the daughter of the late George W. Allen, of New York city, and the lady survives him. He also leaves two children, Dr. Allen Levings, who was graduated from his father's Alma Mater this spring, and Mrs. Albert H. Warren, who was married recently at the earnest request of her deceased father. The doctor had been unable to attend to his night practice for several years past, but was strong enough to serve his office patients until very recently. He made his last visit on Decoration Day. Interment at Greenwood.

WILLIAM E. KENNEDY, M. D.

Dr. William E. Kennedy, one of the oldest and best known of the medical fraternity of New Orleans, died June 10. He was born in New Orleans in 1809. In 1833 he graduated in medicine at the University of Pennsylvania, returning to New Orleans and beginning a practice which he has conducted ever since. He was for many years the partner of the late Dr. Warren Stone in conducting the famous Maison Santé of before the war.

MARRIAGES.

DE GROOT—YOUNG.—On June 13, 1883, at the First Presbyterian Church, Stanhope, N. J., by the Rev. C. S. Woodruff, pastor of the Mattison Methodist Episcopal Church, Bayonne City, assisted by the Rev. George Porter, George S. De Groot, M. D., of Mendham, and Miss Ella Young, of Stanhope.

KEITH—DE LISSER.—At home, on Wednesday, June 20, 1883, by the Rev. George Williamson Smith, D. D., Frank L. Keith, M. D., of Bonne Terre, Mo., and Mary Frances, daughter of R. L. De Lisser, of Brooklyn, N. Y.

LLOYD—HINCKLEY.—On Wednesday, June 6, 1883, at South Street Presbyterian Church, Morristown, N. J., by the Rev. Dr. Erdman, Dr. T. Mortimer Lloyd, of Brooklyn, N. Y., and Grace Mary Hinckley, daughter of the late John G. Hinckley.

LOMBARD—COOK.—On Thursday, June 21, at the Church of the Redeemer, New Brighton, Staten Island, by the Rev. Dr. Farley, of Brooklyn, Dr. Warren P. Lombard, of Boston, Mass., and Caroline, daughter of George E. Cook, of New York.

PAINE—JAQUITH.—On June 11, in Andover, Vt., by the Rev. S. B. Eastman, W. L. Paine, M. D., of Stratford, and Mary A. Jaquith, of Andover.

DEATHS.

KERR.—In this city, on June 19, 1883, of valvular disease of the heart, Mark G. Kerr, M. D., aged sixty-eight years.

LLOYD.—In Louisville, Ky., on June 15, Dr. H. C. Lloyd, only son of Dr. John Lloyd, deceased, and Mary R. Lloyd, aged thirty-nine years, two months and nineteen days,
